a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 20/07/09
Central NGR: ST 196455	Hedge ref number: H17
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 2-5m

LENGTH: 337m

WIDTH: 3-5m

PERCENTAGE GAPS: 15%

DESCRIPTION: Hedgerow is mature and comprises predominantly English elm (some of which is dead or diseased). Ground flora does not support typically woodland species but does contain a range of calcareous grassland indicator species including salad burnet, ladies-bedstraw and dwarf thistle

WOODY SPECIES PRESENT[1]	English elm	Blackthorn	Dog-rose
Hawthorn	Field maple		
		Elder	**TOTAL: 5 (+1)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 3	WOOD:	POND:	**TOTAL: 3**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 13/05/09
NGR: ST207450	Hedge ref number; H25
SURVEYOR; Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

HEDGE STRUCTURE:

HEIGHT: 2m

LENGTH: 120m

WIDTH: 2m

PERCENTAGE GAPS: 2% (for gate)

DESCRIPTION: Likely to have been planted fairly recently. The hedge is compact, managed and dense. Species-poor ground flora dominated by ivy and nettle.

WOODY SPECIES PRESENT[1]	Hawthorn	Dog rose	Blackthorn

PERCENTAGE GAPS: 4%

DESCRIPTION:

WOODY SPECIES PRESENT[1]	Hawthorn	Dog rose	Blackthorn
Dogwood	Field Maple	Spindle	Ash
			Wayfaring Tree
Wild Privet	English Oak	English Elm	**TOTAL: 7 (+4)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 4	WOOD	POND	**TOTAL: 4**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

HEDGE STRUCTURE:

HEIGHT: 1.5 - 5m

LENGTH: 40m

WIDTH: 4m

PERCENTAGE GAPS: 0% (but not stock proof)

DESCRIPTION: Wide hedge/broad-leaved woodland, supplemented with additional broad-leaved planting of beech and ash. Possibly not a hedge.

WOODY SPECIES PRESENT[1]	Field Maple	English Oak	Sycamore
Hawthorn	Blackthorn	Apple	Ash
Beech			
			TOTAL: 8

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 4	WOOD: 2	POND	**TOTAL: 6**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 13/05/09
Central NGR: ST197448	Hedge ref number: H42
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

HEDGE STRUCTURE:

HEIGHT: 2 - 3m

LENGTH: 90m

WIDTH: 1 – 1.5m

PERCENTAGE GAPS: 0%

DESCRIPTION: Hedge adjacent to bridleway and is unmanaged (or very infrequently managed) on the track side.

WOODY SPECIES PRESENT[1]	Elder	Hawthorn	Blackthorn
Dog Rose	Dogwood	English Elm	Wild Privet
	Field Maple	Ash	**TOTAL: 7 (+2)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 3	WOOD:	POND	**TOTAL: 3**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 13/05/09
Central NGR: ST199451	Hedge ref number: H47
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 2 - 3m

LENGTH: 130m

WIDTH: 2 - 4m

PERCENTAGE GAPS: 0%

DESCRIPTION:

WOODY SPECIES PRESENT[1]	Field Maple	Hawthorn	Blackthorn
Dog Rose			
	Goat Willow	Ash	**TOTAL: 4 (+2)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 3	WOOD:	POND	**TOTAL: 3**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Hedge Survey Proforma

Site Name: Hinkley	Date: 14/05/09
Central NGR: ST206452	Hedge ref number: H54
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 3m

LENGTH: 170m

WIDTH: 1m

PERCENTAGE GAPS: 2%

DESCRIPTION: Hedge is dominated by Elm at the eastern end and blackthorn at the western end.

WOODY SPECIES PRESENT[1]	Hawthorn	English Elm	Blackthorn
Field Maple	Goat Willow	Dog Rose	
	Apple	Elder	**TOTAL: 6 (+2)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 3	WOOD:	POND	**TOTAL: 3**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Hedge Survey Proforma

Site Name: Hinkley	Date: 14/05/09
Central NGR: ST205451	Hedge ref number: H60
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 2 - 3m

LENGTH: 90m

WIDTH: 1.5m

PERCENTAGE GAPS: 0%

DESCRIPTION:

WOODY SPECIES PRESENT[1]	Hawthorn	Blackthorn	Dog Rose
Field Maple	English Elm		
			TOTAL: 5

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 4	WOOD:	POND	**TOTAL: 4**

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as ‘Hinkley C’) on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now part of AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds. This report summarises the programme of ornithological work undertaken at Hinkley during 2007-09, including the following:

- Breeding bird surveys undertaken between April and July (inclusive) 2007;
- Intertidal and Inshore Marine Surveys undertaken between April 2007 and March 2009 inclusive;
- Daytime Field Surveys undertaken between September 2007 and April 2009 inclusive; and

Nocturnal Field Surveys undertaken between December 2007 and May 2008 inclusive and between August 2008 and March 2009 inclusive.

1.2 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. In 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1.1).

The study area for some of the bird survey work described in this report extends beyond the SSA to include other nearby bird habitats that, at the time that the survey work was undertaken, were assessed as potentially being affected by the construction of Hinkley C. The survey area for each of the bird surveys that was undertaken is described in section 2.2.

1.3 Scheme Description

An area of land directly west of the Hinkley ‘A’ and ‘B’ Power Stations has been identified as having the potential to accommodate nuclear new build. The new power station and the majority of associated permanent terrestrial infrastructure will be situated in fields adjacent to the coast[1], with additional temporary infrastructure located to the south of this (e.g. construction compounds and areas for soil storage).

[1] Extending as far inland as the east-west Green Lane (also a footpath) that runs along the ridge towards the middle of the SSA.

New build will also require additional infrastructure remote from the immediate terrestrial site footprint. This will include a warm water intake and outfall and a marine aggregates jetty extending offshore from the intertidal zone adjacent to the northern SSA boundary.

An upgrade to an exisiting wharf on the River Parrett (to take abnormal indivisible loads) and a bypass around the village of Cannington will also be required to facilitate the construction and operation of the power station. These proposed 'associated developments' have both required considerable ornithological survey work, but this is not summarised in this document.

1.4 Strategic Siting Area Description and Context

The SSA comprises open, gently rolling mixed lowland farmland with hedgerows of variable quality, small scrubby[2] woodlands and occasional standard trees. Much of the area is intensively managed, and there is little semi-natural habitat present away from the cliff edge and the immediate vicinity of the built plant.

The northern SSA boundary lies adjacent to the Bristol Channel from which it is separated by a low cliff, between five and ten metres in height that forms an escarpment between the land and sea. At low tide, the shore adjacent to the SSA comprises a relatively narrow neck of rock (extending to approximately 200m from the cliff and running parallel to it), interspersed with and fringed by muddy sand. Intertidal areas to the west include more extensive areas of mobile sand, while to the east, adjacent to the built nuclear power stations, the intertidal rock platforms, mud and sand extend up to 500m from shore at low water. Further east again, approximately 1km from the proposed build area, the mosaic of intertidal habitats grades into an area of open mud and sand known as Stert Bay.

Areas of land within close proximity to the built nuclear plant have been managed to create a mosaic of habitats. This has been completed through a land management plan; initiatives have included the mowing and harrowing of grassland, establishment and management of scrub and the creation of one of the aforementioned pools. The result has been the establishment of range of habitat types including flower rich grassland (much of which has calcareous influences), woodland, scrub and reedbed.

There are no substantial water-bodies within the SSA boundary, although two streams (Bum Brook on the southern SSA boundary and the Holford Stream in the valley to the south of the Green Lane) run east-west to connect to watercourses within the Bridgewater Bay SSSI. A more substantial drain (or rhyne) forms the boundary between the eastern arm of the SSA and Wick Moor (North Moor). Standing water is also limited in extent, with the largest pools being to the south of the plant sewage works and in the plant nature reserve (Pixies Field).

The eastern boundary of the SSA is formed (moving north to south) by the operational nuclear plant, the Bridgewater Bay SSSI and mixed farmland which has similar characteristics to that found within the SSA boundary. This part of the SSSI consists of an area of flat, open improved grassland which is seasonally grazed. To the south and west of the site there is further mixed farmland and a series of small villages including Wick, Shurton and Knighton.

[2] Given their coastal location it is likely that new growth is intermittently 'burnt off.' As a result the woodlands are dense and have a low canopy. Woodland only occurs (in terms of the planning application boundary) within a few hundred metres of the coast (there is one additional plantation towards the southern boundary – but this is immature).

1.5 Background and Scope

The key potential ornithological issues relating to the development are:

- The effects of direct habitat loss to birds due to land take by the proposed power station, any new access road and construction compounds;
- The effects of indirect habitat loss, i.e. the displacement of birds from the proximity of the proposed development and associated infrastructure as a result of disturbance. Such disturbance may occur as a consequence of construction work, or due to the presence of the power station or associated infrastructure close to nesting or feeding sites or on habitual flight routes;
- The fragmentation of habitat and the potential barrier to movement resulting from a new power station, particularly as a result of the construction of a new access road;
- Thermal regime change (caused by discharge of cooling water) leading to changes in the composition of intertidal benthic communities and the abundance and biomass of individual invertebrate prey species within them; and
- The potential of the impacts identified above to have significant adverse effects on the species that form the cited/designated interest of the European and nationally designated sites adjacent to the planning application boundary.

There is no guidance available that details potentially appropriate methodologies for ornithological survey work aimed at informing EIA for new nuclear power station proposals. The bird survey programme for Hinkley was therefore based on the results of desk study, consultation (with Natural England and RSPB) and professional judgment. The potential for species protected under Schedule 1 of the Wildlife & Countryside Act 1981 (as amended)[3] and/or listed under Annex 1 of the EC Directive on the Conservation of Wild Birds (79/409/EEC), commonly referred to as the Birds Directive[4] to occur within the SSA and surrounding areas was the subject of specific investigation. Migratory water birds forming part of the featured interest of designated sites were also considered. As a result of the desk study, a survey programme incorporating a range of generic bird surveys was instigated.

[3] All species of wild birds are afforded some degree of protection under the Wildlife and Countryside Act 1981 (as amended). Some species are considered to be rare or vulnerable and receive increased protection through their inclusion on Schedule 1 of the Act.

[4] Certain endangered, rare, or vulnerable bird species, which warrant special protection, are included on Annex 1 of the European Communities Council Directive on the Conservation of Wild Birds (79/409/EEC).

2. Methodology

2.1 Desk Study

To understand the ornithological context of the SSA, the locations and qualifying features of Special Protection Areas (SPAs) and Sites of Special Scientific Interest (SSSIs) within 5km of the boundary were determined through the use of the websites www.magic.gov.uk, www.jncc.gov.uk, www.naturalengland.org.uk, and other published sources. There are no established criteria with regard to the distance from a development site that a search should cover, and 2km has been suggested as a sufficient distance in the past (e.g. IEA, 1995). Due to the known ornithological interest of nearby intertidal habitats, however, this search area was extended to 5km for European and nationally important sites[5]. The ornithological interest of non-statutory designated sites within 3km of the proposed new build and associated infrastructure were also considered. The positions of these designations in relation to the SSA are shown on **Figures 2.1** and **2.2**.

A considerable amount of baseline ecological survey work has been conducted at Hinkley during the past 25 years. This has been undertaken by a range of organisations including British Energy's[6] and EDF Energy's conservation wardens, and ecological consultants (commissioned by Nuclear Electric and latterly by British Energy and EDF Energy.). A great deal of baseline survey work was undertaken between 1981 and 1986 in preparation for the submission of the Hinkley 'C' station planning application. This information was made available to Entec by British Energy to help determine the scope of the ornithological survey programme. Additional data from survey work commissioned by Magnox in association with the decommissioning of Hinkley 'A,' and the West Hinkley Wind Farm Environmental Statement (this wind farm proposal is for land adjacent to the proposed build area) were also used to inform the work.

In addition to this information, a number of further primary sources of data were identified and used to inform the work. These included:

- The results of annual breeding and wintering bird surveys conducted by British Energy's Conservation Warden and ADAS on parts of British Energy's land ownership (summarised in the annual land management reviews by ADAS / British Energy);
- A history of the birds of Somerset (Ballance, 2006);
- Somerset Birds 2005-09 (the annual county bird reports); and
- Wetland Bird Survey annual report 2008/09 (Calbrade *et al.*, 2010).

[5] This allowed greater contextual information with regard to bird populations (e.g. for the potential for movement between sites). This could have been re-evaluated if geese or swans (or large numbers of other species that make considerable daily commutes between feeding and roosting areas) were located during the work.

[6] British Energy became part of EDF Energy in 2009.

A thorough desk study was undertaken with Wetland Bird Survey[7] (WeBS) data obtained from the British Trust for Ornithology and general bird sightings records obtained from the Somerset Ornithological Society.

2.2 Bird Surveys

2.2.1 Overview of Survey Area

The key objective of the bird surveys undertaken at Hinkley during 2007-09 was to establish a suitable baseline for the assessment of the potentially significant effects on birds of a new nuclear power station and associated infrastructure. The breeding bird community within the SSA and surrounding land was characterised though territory mapping surveys. The numbers and diversity of bird species feeding, loafing[8] or commuting through the intertidal zone and inshore waters adjacent to the SSA and the existing power station were investigated through regular watches at a number of suitable coastal locations. In addition, walkover (field) surveys were conducted during daylight hours and at night in order to determine whether any significant congregations of feeding, roosting or loafing birds occurred on fields (in particular wildfowl, waders and raptors) within or in close proximity to the SSA. The area within which each bird survey methodology was undertaken is described in greater detail in Sections 2.2.2-2.2.5.

2.2.2 Territory Mapping

Territory mapping surveys based on the BTO's Common Bird Census (CBC) methodology (Marchant, 1983) were carried out in 2007 in areas within 1km of the land that was owned by British Energy (excluding the built nuclear plant). These surveys therefore covered the entire SSA boundary. Of the area covered in 2007, 75ha / 0.75km^2 of land was under British Energy's ownership (of which the built power station accounted for 42ha / 0.42km^2), and outside this area access permission was only achieved for Wick Moor, which is part of the Bridgwater Bay SSSI.

Within British Energy's land ownership and on the SSSI, transects no further than 50m apart were walked across all open habitats, while all field boundaries, the edge of the small reedbed and the edge of the small belts of semi-natural woodland were also walked. Outside British Energy's land ownership and Wick Moor SSSI, access was restricted, and surveys could only be conducted from public footpaths and bridleways, road and tracks. Therefore, outside areas with access permission, a series of transects were walked to enable characterisation of the wider bird community.

While the areas outside the British Energy land ownership and SSSI are very well served by footpaths, it is clear that robust breeding densities cannot be reliably derived from them as a result of the survey work. The aim of the survey, in conjunction with data from other sources (such as the West Hinkley Wind Farm application) was to characterise the bird community of the area and to provide a basis to assess the value of the community potentially affected by the

[7] WeBS is the main scheme for monitoring the numbers of non-breeding waterbirds in the UK. The principal aims of WeBS are to identify population sizes, determine trends in numbers and distribution and to identify important sites for waterbirds. WeBS counts are predominantly undertaken by skilled volunteers.

[8] Being inactive, but not actually roosting.

build. The survey area for the territory mapping work and British Energy's land ownership boundary (during the 2007 survey), are shown on **Figure 2.3**.

While eight to ten visits are the norm for CBC sites being monitored over the long-term, where territory mapping is being used for the purpose of assessing potential environmental impacts it is generally accepted that three to four visits are sufficient to determine the numbers and densities of breeding birds with reasonable accuracy. Four survey visits were therefore undertaken at Hinkley. It took a total of three man days to complete each survey visit (two surveyors worked together). The dates on which surveys were conducted were as follows:

- 10 and 11 April 2007;
- 23 and 24 May 2007;
- 13 and 15 June 2007;
- 19 and 21 June 2007.

Supplementary records of birds recorded outside timed surveys were also used when compiling the final territory map, along with information supplied by Martin Sage of ADAS (who are responsible for the conservation management of British Energy's land ownership and conduct annual bird surveys in collaboration with the site warden).

2.2.3 Intertidal and Inshore Marine Bird Survey

In order that any potential disturbance effects on birds using the intertidal areas and inshore marine waters adjacent to the SSA could be evaluated, intertidal and inshore marine bird surveys were undertaken between April 2007 and March 2009 inclusive. Surveys were undertaken on a regular basis during the entire survey period from five observation points. OS Grid References of these are as follows:

- ST19131 45837;
- ST19923 46162;
- ST20838 46284;
- ST21468 46318;
- ST21786 46088.

These locations, and the areas surveyed from them are shown on **Figure 2.4**. All waders, wildfowl and seabirds flying over the intertidal area and the inshore waters up to 500m from the shore were systematically recorded[9]. Numbers and apparent behaviour of all species were noted and their position in relation to the survey location estimated (with the aid of rangefinders).

---

[9] 500m offshore from each location was selected as the maximum threshold for recording on the basis that all relevant bird species within this distance were generally identifiable in normal sea states and weather conditions, and accurate and comparable counts could therefore be made. It is also apparent that any disturbance effects are most likely to affect birds occurring in relatively close proximity to the proposed power station. During quiet periods surveyors noted the presence of seabirds and large flocks of species outwith this survey area, while the open expanse of mud in Count Sector 5 was generally systematically recorded, meaning low water counts extended to 700-800m from the observation point.

Some limited parts of the survey area, particularly to the east and west of Location 2 were sufficiently distant from the observation point that individual birds, particularly those foraging on pool edges and in gullies could have been missed. In addition, there were several small blind spots in coverage around the upper reaches of the shore, due to the topography of the coast. The surveyors collected supplementary information from these areas during walks between the survey locations, and this is unlikely to have resulted in concentrations of birds being missed.

Table 2.1 Characteristics of the Shore within the Count Sectors[10]

Count Sector	Description of Extent and Characteristics of Shore at Mean High Water	Description of Extent and Characteristics of Shore at Mean Low Water
1	Approximately 10 to 20m of sand remains exposed on the upper shore throughout much of the sector. A strandline, mainly consisting of brown seaweed is present. The area of sand borders a superlittoral[11] storm beach. The eastern part of the sector has more rock at high water than sand.	Approximately 350-400m of open shore with large areas of sand bordered to the east by rock platforms and loose boulders. Some pools are present in the rocky areas, these being dominated by brown seaweeds.
2	Between 0 and 30m of exposed rock platforms partially covered by areas of pebble / boulder storm beach and a strand line dominated by brown seaweeds.	Slightly in excess of 200m of mainly solid rock platforms with some overlying large loose rocks. Some shallow gullies and pools dominated by brown seaweeds.
3	A strip of between 0 and 10m of loose boulders, some rock with pockets of shingle and an intermittent strand line.	Approximately 400-450m of open rock platforms traversed by narrow east-west bands of sand and mud and bordered by an extensive and dynamic area of open sand and mud in the western part of the count sector.
4	A boulder shore / storm beach of between 0 and 15m in width, with a brown seaweed dominated strand line. A relatively linear band of sand runs east from the survey location parallel to the coastal defence of the built nuclear power station.	Approximately 400-450m of exposed shore featuring a mosaic of areas of open rock (particularly around the warm water outfall) and extensive mud covered by loose pebbles and boulders with some pools
5	0 to 5m of sand with occasional boulders and a strand line following neap tides. Some areas of boulder shore/ storm beach in the western part of the sector.	Between 700 and 800m of very extensive open mud. Patchy areas of rock close to the survey location and in the western part of the count sector.

The aim of the survey work was to record the numbers, diversity and activity of birds present and to identify areas of importance for birds (in the intertidal zone and inshore marine waters) during the tidal cycle in relation to the SSA. On each survey day, survey was conducted over six full hours, so that any changes or patterns in bird distribution across the tidal cycle could be identified. During each hour of survey, the intertidal area and inshore waters within each count sector were scanned using binoculars for 45 minutes, and all species present or commuting

[10] This basic summary of the dominant intertidal habitats within each sector is included here to inform the reader. A more formal and scientific description of the shore will be produced as part of the marine **biological studies that will be an integral part of the EIA for the site.**

[11] The supralittoral zone is that area of the shoreline not normally covered by water, being above the tide line.

through were recorded[12]. There was then a ten to fifteen minute break in survey, to allow the surveyor to rest his eyes, walk between survey locations and regain focus before the next snapshot survey commenced.

During the first year of survey (April 2007 to March 2008 inclusive), intertidal surveys were undertaken approximately twice each week. During this period, a total of 495 hours of intertidal survey was completed, equating to 99 hours of observation at each survey location. Results from the surveys indicated that the intertidal area adjacent to the SSA was not used by large numbers of species that appear as cited/designated features of statutory designated sites within 5km, and therefore a less intensive survey programme was carried out in the second year (April 2008 to March 2009 inclusive). During this period, surveys were undertaken approximately once each week, with a total of 187.5 hours of survey completed, equating to 37.5 hours at each location. Table 2.2 presents the dates on which surveys were undertaken in the two survey years.

Table 2.2 Intertidal and Inshore Marine Survey Dates

Month	2007/08	2008/09
April	3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 24 & 25	1, 9, 18 & 24

2.2.4 Daytime Field Surveys

In order to identify any significant concentrations of birds (particularly bird species listed as part of the qualifying interest of nearby designated sites) that might be using fields adjacent or close to the new build for foraging, loafing or roosting, field-by-field (walkover) surveys were

[12] The surveyor used a telescope to confirm identity and activity of birds as necessary. High quality rangefinders were used throughout the season to improve distance estimation, although these were not generally of use in estimating the distance of individual birds on the sea (due to the more reflective nature of the water than the bird often preventing a confident estimate of distance).

undertaken during daylight hours within approximately 1km of the initial works area (identified by British Energy) at Hinkley. This survey area covered the entire SSA plus the terrestrial part of the Severn Estuary SPA and Ramsar site and Bridgwater Bay SSSI adjacent to the SSA.

The daytime field surveys were carried out as instantaneous counts that recorded a snapshot of the birds present within each field at the time it was surveyed. The surveys involved scanning the fields from suitable local vantage points and recording the birds within them. Each field was given a unique identification number, which was logged onto a recording sheet during each survey, together with details of the species seen, their numbers and activity (e.g. foraging, loafing, roosting, etc.). The habitat and crop types in each of the fields in which birds were seen were also recorded on each visit. Although all species were recorded during the surveys, particular emphasis was given to the following:

- Any species cited/designated in the Severn Estuary SPA, Severn Estuary Ramsar site or Bridgwater Bay SSSI descriptions, either as assemblage species, or for their internationally or nationally important winter or passage populations at these sites;
- UK BAP, Local BAP species and species listed under Section 41(1) of the Natural Environment and Rural Communities Act 2006[13];
- Species of conservation concern (BoCC Red or Amber Listed species);
- Species listed in Schedule 1 of the Wildlife and Countryside Act 1981 (as amended);
- EU Birds Directive Annex 1 species not covered in these categories;
- All other wader species;
- All other wildfowl species (swans, ducks and geese); and
- Flocks of 50 or more birds of any other species (e.g. wintering passerines).

Figure 2.5 shows the field identification numbers and survey area for the daytime field surveys. Each month, a full audit of habitat and crop types within each field was carried out using a predetermined set of habitat/crop type categories, with further categories added during the survey if necessary. The predetermined habitat/crop types included: *Ploughed*, *Winter-sown Cereal*, *Rape*, *Brassicas*, *Pasture*, *Horse Paddocks*, *Set-aside*, *Cereal Stubble*, *Rough Grassland*, *Woodland and Scrub*. The idea of this was that a link could be drawn between any large concentrations of birds or consistently occurring species and crop type.

[13] The Secretary of State for Environment, Food and Rural Affairs was required under Section 41(1) of the Natural Environment and Rural Communities Act (NERC) 2006 to prepare a list of the species and habitats considered to be of principal importance for the purpose of conserving biodiversity in England. Under Section 41 of the act, consultation was required with Natural England in determining the species and habitats to appear on the list and also to take steps (where they are reasonably practicable), and promote the taking of steps by others, to further the conservation of the habitats and species on the list. The Section 41 list was published in 2008 and replaced the list published by Defra in 2002 under Section 74 of the Countryside and Rights of Way (CRoW) Act 2000. Planning Policy Statement 9 (PPS9) refers to the steps that local authorities should take through the planning process in relation to species and habitats of principal importance. The new list of species of principal importance is found at http://www.defra.gov.uk/wildlife-countryside/biodiversity/sect41-nerc.htm.

After initial surveys undertaken on 21 and 24 September (a single survey undertaken over two days) and 26 October 2007, the frequency of survey was intensified to approximately once each week between November 2007 and March 2009 inclusive. Table 2.3 shows the dates on which daytime field surveys were undertaken. When poor weather conditions prevented the survey being completed in one day, the survey was undertaken over two (usually consecutive) days as indicated by the dates enclosed in square brackets.

Table 2.3 Daytime Field Survey Dates

Month	2007/08	2008/09

March	11, 14, [17-18] & 21	5, [10-11], 18 & 24

2.2.5 Nocturnal Field Surveys

Nocturnal bird surveys were included within the scope of the baseline work at the request of Natural England. The aim of these surveys was to establish whether there was any nocturnal use of coastal fields during the winter period (December to February), particularly in the Wick Moor area[14] (which can be seasonally inundated) which Natural England are responsible for managing, and which is adjacent to the SSA boundary.

These nocturnal field surveys involved scanning the fields using night vision equipment. Surveys followed a predetermined route chosen to cover the coastal development area adjacent to the shoreline, the upper intertidal zone, and Wick Moor area. In addition, a series of vantage-points (which included the five coastal survey locations used during the intertidal surveys) were used to collect further data, with the surveyor stopping at each to scan for several minutes (long enough of the visible area to be systematically scanned several times). During each survey, the numbers of each bird species and the number of the field in which they were present were

[14] This forms an inland spur of the Severn SPA and Ramsar Site and the Bridgwater Bay SSSI.

recorded, together with the activity of the birds (e.g. foraging, roosting, etc.) if apparent. The route used during the nocturnal surveys is shown on **Figure 2.6**.

Due to the limited effectiveness of even the most sensitive night vision equipment, nocturnal visits were generally carried out within a week of full moon to increase the chance of there being good level of background light. During good background light conditions more extensive foraging will occur at night in some species, potentially making them more detectable.

Prior to at least one of the nocturnal surveys each month, a field survey was undertaken. This enabled the observer to identify areas that had recently become inundated (and therefore might be good areas for waterbirds) and feeding areas that were being used in the day that might also be used at night. The surveyor had the freedom to amend the route in response to the findings of these surveys. In the event, however, the same approximate route was followed during each survey, as field use was very limited and the key areas for birds were all on the route of thetransect.

Two survey visits were undertaken each month between December 2007 and May 2008 inclusive and August 2008 and March 2009 inclusive on the following dates, with the nearest date of the full moon in parenthesis.

2007

- December 21 & 26 (December 25).

2008

- January 17 & 24 (January 22);
- February 18 & 21 (February 21);
- March 17 & 19 (March 21);
- April 14 & 20 (April 20);
- May 19 & 20 (May 20);
- August 14 & 21 (August 16);
- September 17 & 18 (September 15);
- October 13 & 16 (October 14);
- November 18 & 19 (November 13); and
- December 10 & 13 (December 12).

2009

- January 10 & 13 (January 11);
- February 6 & 10 (February 9); and
- March 10 & 14 (March 11).

3. Results

3.1 Designated Sites of Ornithological Importance

3.1.1 European Designated Sites

The Severn Estuary SPA is located adjacent to the northern boundary of the SSA. The SPA was classified on the basis of its wintering bird interest and for the large numbers of waterfowl that regularly use the site.

The SPA qualifies under Article 4.1 of the Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex 1 of the Directive:

Over winter:

- Tundra (Bewick's Swan) (*Cygnus columbianus bewickii*), 280 individuals representing approximately 3.9% of the wintering population in Great Britain (5 year peak mean 1991/2 - 1995/6).

The site also qualifies under Article 4.2 of the Directive by supporting populations of European importance of the following migratory species:

Over winter:

- Russian white-fronted goose (*Anser albifrons albifrons*), 2,664 individuals representing 0.4% of the North-western Siberian. North-eastern European and North-western European wintering population (5 year peak mean 1991/2 - 1995/6);
- Dunlin (*Calidris alpina alpina*), 44,624 individuals representing at least 3.2% of the wintering Northern Siberian, European and Western African population (5 year peak mean 1991/2 - 1995/6);
- Gadwall (*Anas strepera*), 282 individuals representing approximately 0.9% of the wintering North-west European population (5 year peak mean 1991/2 - 1995/6);
- Redshank (*Tringa totanus*), 2,330 individuals representing at least 1.6% of the wintering Eastern Atlantic population (5 year peak mean 1991/2 - 1995/6); and
- Shelduck (*Tadorna tadorna*), 3,330 individuals representing at least 1.1% of the wintering Northwestern Europe population (5 year peak mean 1991/2 - 1995/6).

The SPA also qualifies under **Article 4.2** of the Directive by regularly supporting at least 20,000 waterfowl:

> *"Over winter, the area regularly supports 93,986 individual waterfowl (5 year peak mean 1991/2 - 1995/6) including: Gadwall, Shelduck, Pintail, Dunlin, Curlew, Redshank, Bewick's Swan, Wigeon, Lapwing (Vanellus vanellus), Teal, Mallard (Anas platyrhynchos), Shoveler, Pochard, Tufted Duck (Aythya*

fuligula), Grey Plover (Pluvialis squatarola), White-fronted Goose and Whimbrel."

Subsequent to the publication of the data above (as included in the Natura 2000 Standard Data Form), the following changes have been suggested by the SPA Review (Stroud *et al.*, 2001).

Removal of the following species that originally qualified under Article 4.2 of the Directive[15]:

- Russian white-fronted goose;
- Gadwall.

Addition of the following species that now qualify under Article 4.2 of the Directive by supporting populations of European importance:

- On passage:
    - Ringed Plover *Charadrius hiaticula*, 655 individuals representing at least 1.3% of the Europe/Northern Africa wintering population (5 year peak mean 1991/2 - 1995/6).
- Over winter:
    - Curlew *Numenius arquata*, 3,903 individuals representing at least 1.1% of the wintering European population (5 year peak mean 1991/2 - 1995/6);
    - Pintail *Anas acuta*, 599 individuals representing at least 1.0% of the wintering Northwestern Europe population (5 year peak mean 1991/2 - 1995/6).

The SPA Review has yet to be formally adopted, although in practice SPA Review information (regarding additional species) is given the same credence by nature conservation consultees as that contained on the Natura 2000 Data Sheets.

The Severn Estuary has been recently designated a Special Area of Conservation (SAC), and some limited information is included here for contextual purposes. The area contains species and habitats that are rare or threatened in a European context: migratory fish such as Twaite (*Alosa alosa*) and Allis shads (*Alosa fallax*) and sea (*Petromyzon marinus*) and river lampreys (*Lampetra fluviatilis*); Atlantic salt meadows (often referred to as salt marsh), mud and sandflats, estuaries and subtidal reefs.

3.1.2 Internationally Designated Sites

The Severn Estuary Ramsar Site, which shares a common boundary with the Severn Estuary SPA and Bridgwater Bay SSSI in this location (refer **Figure 2.1**), is adjacent to the north of the SSA. The Severn qualifies as a Ramsar site under Criterions 5 and 6 of the Ramsar Convention due to the internationally important bird assemblage and individual populations that occur.

[15] For the purposes of this assessment, the importance of the survey area to gadwall has still been considered against the Severn Estuary SPA qualifying population. The desk study and surveys found no recent evidence of Russian white-fronted goose using the survey area.

Qualifying ornithological interest listed on the Ramsar Information Sheet is summarised as follows:

- During winter the site supports an assemblage of 70,919 waterfowl (5 year peak mean 1998/999 - 2002/03).

Under Criterion 6, during the winter the site supports internationally important numbers of:

- Tundra (Bewick's) swan (*Cygnus columbianus bewickii*), 229 individuals representing an average of 2.8% of the GB population (5 year peak mean 1998/999 - 2002/03);
- Greater white-fronted goose (*Anser albifrons*), 2,076 individuals representing an average of 35.8% of the GB population (5 year peak mean for 1996/7 - 2000/01);
- Common shelduck (*Tadorna tadorna*), 3,223 individuals representing an average of 1% of the north-western European population (5 year peak mean 1998/99 - 2002/03);
- Gadwall (*Anas strepera strepera*), 241 individuals representing an average of 1.4% of the GB population (5 year peak mean 1998/99 - 2002/03);
- Dunlin (*Calidris alpina alpina*), 25,082 individuals representing an average of 1.8% of the Western Siberian/Western European population (5 year peak mean 1998/99 - 2002/03);
- Redshank (*Tringa totanus totanus*), 2,616 individuals representing an average of 1% of the population (5 year peak mean 1998/99 - 2002/03).

Species identified on the Ramsar Information Sheet for possible future consideration under Criterion 6 are as follows:

- Lesser black-backed gull (*Larus fuscus graellsii*), a breeding season population of 4,617 apparently occupied nests, representing an average of 2.8% of the breeding population (Seabird 2000 Census);
- Ringed plover (*Charadrius hiaticula*), 740 individuals representing an average of 1% of the European/North-west African passage population (5 year peak mean 1998/999-2002/03);
- Teal (*Anas crecca*), 4,456 individuals representing an average of 1.1% of the north-west European wintering population year (5 peak mean 1998/99 - 2002/03);
- Pintail (*Anas acuta*), 756 individuals representing an average of 1.2% of the population (5 year peak mean 1998/99 - 2002/03).

In addition to these species currently and potentially forming the cited/designated interest of the Ramsar Site, a number of species occur at nationally important levels during the breeding season, passage periods and over winter. These are:

- Herring gull (*Larus argentatus argentatus*), 1,540 apparently occupied nests, representing an average of 1.1% of the GB breeding population (Seabird 2000 Census);

- Little egret (*Egretta garzetta*), 17 individuals, representing an average of 1% of the GB passage population (5 year peak mean 1998/99 - 2002/03);
- Ruff (*Philomachus pugnax*), 12 individuals, representing an average of 1.7% of the GB passage population (5 year peak mean 1998/99 - 2002/03);
- Whimbrel (*Numenius phaeopus*), 333 individuals, representing an average of 11.1% of the GB passage population (5 year peak mean 1998/99 - 2002/03);
- Curlew (*Numenius arquata arquata*) 2,021 individuals, representing an average of 1.3% of the GB passage population (5 year peak mean 1998/99 - 2002/03);
- Common greenshank (*Tringa nebularia*), 26 individuals, representing an average of 4.3% of the GB passage population (5 year peak mean 1998/99 - 2002/03);
- Wigeon (*Anas penelope*), 4,658 individuals, representing an average of 1.1% of the GB wintering population (5 year peak mean 1998/99 - 2002/03);
- Northern shoveler (*Anas clypeata*) 297 individuals, representing an average of 2% of the GB wintering population (5 year peak mean 1998/99 - 2002/03);
- Common pochard (*Aythya farina*) 1,118 individuals, representing an average of 1.8% of the GB wintering population (5 year peak mean 1998/99 - 2002/03);
- Water rail (*Rallus aquaticus*), 11 individuals, representing an average of 2.4% of the GB wintering population (5 year peak mean 1998/99-2002/03);
- Spotted redshank (*Tringa erythropus*) 10 individuals, representing an average of 7.3% of the GB wintering population (5 year peak mean 1998/99 - 2002/03).

In addition to the bird interest the site has also been designated for extensive areas of intertidal sand and mudflats, intertidal rock platforms, vegetated shingle beach and maritime grasslands with freshwater and brackish ditches, which support nationally important plant species. Sea lamprey (*Petromyzon marinus*) occurs at the site at an internationally important level.

3.1.3 Nationally Designated Sites

Bridgwater Bay SSSI lies adjacent to the northern boundary of the SSA and also takes in land to the east and south of the SSA, including the Parrett Estuary (which includes Huntspill and Stert Flats) and the open coastal fields at Wick Moor. Hinkley is located at the western end of the SSSI, which extends in a north-easterly direction along the coast to Brean Down, just south of Weston-Super-Mare and covers a total area of 3,574ha (35.74km^2). Its position is shown on **Figure 2.1**.

The SSSI is of national importance for the succession of habitats it supports. These include intertidal mud, wave-cut platforms, cliffs, sand dunes, shingle ridges and extensive areas of saltmarsh. Associated with these habitats are internationally and nationally important assemblages of wintering and passage migrant waders and waterfowl, and a diverse invertebrate fauna. The SSSI supports internationally important numbers of passage whimbrel[16] and black-

---

[16] The information contained in the SSSI site description is dated, and for black-tailed godwit may never have been wholly accurate. Since the early 1980s there has been a decline in the whimbrel population using Bridgwater Bay. It is possible that birds have moved to other locations within the estuary, but the precise reason for the decline is

tailed godwit (*Limosa limosa*) and nationally important numbers of overwintering dunlin and wigeon. Shelduck use the bay as a moulting ground, and are also present in nationally important numbers.

The Severn Estuary is used by internationally important numbers of dunlin, shelduck, wigeon, curlew, redshank and teal and nationally important numbers of ringed plover and grey plover. Knot (*Calidris canutus*), turnstone (*Arenaria interpres*), snipe (*Gallinago gallinago*) and mallard also occur. Bridgwater Bay SSSI is used by a substantial proportion of the overall waterfowl and wader populations of the Severn Estuary. The SSSI is also ecologically linked to the Somerset Levels, which provide additional winter-feeding grounds for large numbers of waders and wildfowl.

Blue Anchor to Lilstock Coast SSSI, designated due to its geological interest, is located approximately 350m to the west of the proposed new build site and partially overlaps with Bridgwater Bay SSSI.

3.1.4 Non Statutory Designated Sites

Fifteen non-statutory designated sites (known as County Wildlife Sites in Somerset) are present within 3km of the SSA. A summary of conservation interest from information provided by SERC is included in Table 3.1 below.

Table 3.1 Non-statutorily Designated Sites Information

CWS Reference Number	Name	Brief Description*	Distance from SSA
ST24/043	Hinkley	Species-rich scrub, coastal grassland and broad-leaved woodland with ponds and areas of improved grassland.	CWS lies within the planning application boundary.
ST04/051	Blue Anchor to Lilstock Cliff	Coastal cliffs with unimproved calcareous grassland and scrub habitats from Blue Anchor to Lilstock.	Approximately 2.2k to the west.
ST14/027	Cross Elms	Small field of unimproved grassland and adjacent semi-natural broad-leaved woodland.	Approximately 1.8km to the west.
ST14/045	Pophams Park	A small area of deciduous woodland.	Approximately 2.2km to the south.
ST14/046	Honilbere Wood	A large tract of hedged, embanked and ditched ancient semi-natural woodland occupying very wet-lying ground on coastal strip of county (north of Stringson).	Approximately 1.3km to the west.

unknown. It remains of national importance (Archer, *in litt*). Black-tailed godwit numbers, in contrast, are increasing at regional and national level. This is due to the success of the Icelandic breeding population, and numbers of birds using the area on autumn passage regularly exceed the threshold of national importance, while winter numbers are also approaching this threshold (Archer, *in litt*).

CWS Reference Number	Name	Brief Description*	Distance from SSA
ST14/047	Fairfield Wood	A large tract of high-forest, partly ancient woodland straddling the stream which marks the boundary between Nether Stowey and Stringston parishes on essentially level and rather wet-lying ground amidst arable and grassland.	Approximately 2.7km to the south-west.
ST14/054	Quarry Copse	A small copse of Ancient Woodland on relatively high ground north of Stringston.	Approximately 2.8m to the south-west.
ST14/070	Martin's Wood	A more or less square tract of ancient semi-natural woodland hedge, ditched and embanked all round and with a small stream flowing eastwards along its southern edge.	Approximately 1.4km to the south-west.
ST14/099	Fairfield House Park	Parkland site as marked on the 1st edition Ordnance Survey map with an important assemblage of veteran trees.	Approximately 1.6km to the south-west.
ST14/103	Cole Pool Field	Field with unimproved neutral and marshy grassland and semi-improved areas.	Approximately 0.8km to the south south-west.
ST24/001	Monk Wood	Broad-leaved ancient woodland.	Approximately 1.5km to the south south-east.
ST24/002	Wick Park Covert	Ancient semi-natural broad-leaved woodland bisected by road.	Approximately 1.4km to the south-east.
ST24/003	Mud House Copse	Ancient semi-natural broad-leaved woodland.	Approximately 1.2km to the south-east.
ST24/004	Claylands Corner Verge	Roadside verge with species-rich unimproved neutral grassland supporting diverse invertebrate fauna, flanked by tall hedge/tree-belt and with advancing scrub.	Approximately 2.8km to the south-east.
ST24/017	New Barn Wood	Ancient semi-natural broadleaved woodland with broadleaved plantation.	Approximately 2.9km to the south-east.

*There is no indication from the information received that wintering or passage birds are an important feature of any of these sites.

3.2 Desk Study Data

3.2.1 Wetland Bird Survey and Somerset Ornithological Society Data

The following information was obtained from the BTO's Wetland Bird Survey (WeBS) and from the Somerset Ornithological Society:

- WeBS Core Counts[17] for count sectors within Bridgwater Bay (that are within 2km of the SSA). The Core Count or 'high tide' data for the five most recent years was

[17] The WeBS Core Counts survey is the principal scheme of The Wetland Bird Survey. Counts are made annually at around 2,000 wetland sites of all habitats, primarily estuaries and large still waters. Monthly co-ordinated counts are made at predetermined count sectors, principally from September to March, with fewer observations made during the summer months. Core Counts on estuaries are usually carried out around high tide and the Core Count year runs from July to June of the following year.

obtained (not all sectors have five years of data available). **Figure 3.1** shows the location of the count sectors for which Core Count data were obtained. Table 3.2 provides a summary of the years and months for which these data were obtained;

- WeBS Low Tide Counts[18] for count sectors within Bridgwater Bay (that are at their closest less than 2km from the SSA). Data were obtained for the most recent winter in which the count sector was surveyed (2008/09 for BV691-7 and 2002/03 for BV670 and 690). **Figure 3.1** also shows the location of the count sectors for which Low Tide Count data were obtained. Table 3.2 provides a summary of the years and months for which these data were obtained;

- Somerset Ornithological Society: general bird sightings records within approximately 3km of the initial British Energy works area were obtained from the Somerset Ornithological Society in 2008. These covered the period 1997 to 2007 inclusive (data for 2008 was unavailable at the time of writing the Hinkley Third Interim Bird Report). It should be noted that OS Grid References for the sightings are not available and therefore only broad locations have been provided (i.e. Hinkley Point, Knighton, Lilstock and Stolford). Additionally, no details on the behaviour of the birds recorded were provided.

Table 3.2 WeBS Core Count and Low Tide Counts: Years and Months of Data Obtained

WeBS Count Sector No.	Area Covered	SPAs	Years (months) of Data Obtained[19]
Core Counts			
13411	A large area encompassing much of the Stert Flats in Bridgwater Bay that includes all of Count Sector 5.	Severn Estuary SPA[20]	July 2004 to June 2009
Low Tide Counts			
BV670	Approx. 2km north east of the intertidal survey area	Severn Estuary SPA	2002-03 (Jan-Feb)
BV690	Approx. 1km north east of the intertidal survey area	Severn Estuary SPA	2002-03 (Nov-Dec, Feb)
BV691	Approx. 1km east of the intertidal survey area	Severn Estuary SPA	2008-09 (Dec-Feb)

[18] WeBS Low Tide Counts are co-ordinated counts of feeding and roosting waterbirds on estuaries, each month between November and February. Counts are carried out on pre-established subdivisions (count sectors) of intertidal habitat during the period two hours either side of low tide. The WeBS Low Tide Counts scheme aims to cover most individual estuaries approximately once every six years, although on some sites more frequent counts are made.

[19] All periods are inclusive.

[20] As the SPA, Ramsar Site and SSSI share common boundaries, all surveys covering the SPA also therefore covered the other designated areas.

WeBS Count Sector No.	Area Covered	SPAs	Years (months) of Data Obtained[19]
BV692	Approx. 1km east of the intertidal survey area	Severn Estuary SPA	2008-09 (Nov-Feb)
BV693	Approx. 1km east of the intertidal survey area	Severn Estuary SPA	2008-09 (Nov-Feb)
BV694	Approx. 1km east of the intertidal survey area	Severn Estuary SPA	2008-09 (Nov-Feb)
BV695	Includes much of the southeast corner of the survey area for the daytime field surveys, including Wick Moor and North Moor.	Severn Estuary SPA	2008-09 (Nov-Feb)
BV696	The western half of this WeBS Count Sector includes all of Count Sector 5.	Severn Estuary SPA	2008-09 (Nov-Feb)
BV697	This area is almost contiguous with the area covered by Count Sectors 1, 2, 3 and 4.	Severn Estuary SPA	2008-09 (Nov-Feb)

The peak WeBS Core Count and peak and mean 2008/09 Low Tide counts for each species are presented in **Appendix A, in Tables A1 and A2 respectively**. **Tables B1 and B2 in Appendix B** presents a summary of the data provided by the Somerset Ornithological Society (the maximum count of each species at each location for cited/designated and non-cited/designated species respectively).

WeBS data has indicated that several species forming part of the cited/designated interest of statutorily designated sites occur on the Stert Flats immediately to the east of the Hinkley survey area.

Peak counts during 2004/05 to 2008/09 inclusive, in WeBS Core sector 13411, which covers much of the Stert Flats included:

- 11 Bewick’s swan, 2,900 shelduck, 950 wigeon, 1,800 teal, 70 mallard, , 44 pintail, 21 shoveler, 8,400 lapwing, 780 ringed plover, 520 grey plover, 11,100 dunlin, 148 black-tailed godwit, 1,550 curlew, 28 whimbrel and 950 redshank. Numbers of teal, shoveler, lapwing, ringed plover, black-tailed godwit and whimbrel show considerable variation between years.

Low Tide count data for those sectors counted in 2008/09 that form the western part of the Stert Flats (BV691-7 inclusive) indicated that a number of species forming part of the cited/designated interest of statutorily designated sites occurred in this area. Low tide counts across all these count sectors included:

- 394 shelduck, 727 wigeon, 121 teal, 98 mallard, 131 pintail, 58 ringed plover, 319 grey plover, 155 lapwing, 4,232 dunlin, 355 curlew and 169 redshank.

Low tide counts conducted in Sector BV696 (which covers all of Count Sector 5) included:

- 185 shelduck, 485 wigeon, 73 teal, 57 pintail, 43 lapwing, 230 dunlin, 98 curlew and 36 redshank.

Very few birds were recorded in Low Tide sector BV695 (which covers farmland immediately to the east of the power stations). Low tide counts in Low Tide Sector BV697 (which covers much the same area as Count Sectors 1-4) included:

- 65 shelduck, 185 wigeon, 35 pintial, 35 ringed plover and 28 curlew.

White-fronted goose, gadwall, pochard and tufted duck were not recorded on either Core Count or Low Tide counts during 2004/05 - 2008/09 and 2008/09 respectively

Of the species that do not appear as cited/designated features of either the Severn Estuary SPA/Ramsar site or Bridgwater Bay SSSI, peak counts of 19 cormorant, 42 little egret, 200 oystercatcher, 68 avocet, 1,950 golden plover, 1,650 knot, 140 sanderling, 32 snipe, 43 bar-tailed godwit, 12 spotted redshank, 5 greenshank and 165 turnstone were recorded in WeBS Sector 13411 (although counts of oystercatcher, golden plover, knot, sanderling and turnstone showed considerable between year variation). The Low Tide data indicated that good numbers of knot occurred on the Stert Flats in 2008/09 (combined peak count of 384 birds for sectors BV691-97 inclusive). Peak counts in WeBS count sectors located within the intertidal survey area included: 40 oystercatcher, 12 purple sandpiper and 26 turnstone, all in BV697.

3.2.2 Passage and Wintering Bird Information from the West Hinkley Wind Farm Environmental Statement (Dulas, 2006)

The proposed West Hinkley Wind Farm was a nine turbine scheme for which an Environmental Statement was submitted to the local planning authority in December 2006. This scheme has been bought out by EDF Energy.

The wind farm would have been partially within and partially to the west of the SSA, although there is a considerable degree of overlap between the two planning application boundaries. As a result of this, much of the baseline data collected for the wind farm is of relevance to the new nuclear proposal.

In order to provide baseline information on the bird interest of the wind farm area, breeding bird surveys, walkover field surveys and vantage point surveys were undertaken during 2003-06. The wind farm application area and the SSA for the new nuclear build are shown on **Figure 3.2**.

Breeding Bird Surveys

Two breeding bird surveys were undertaken in relation to the wind farm application, the first by Ecology Consulting in 2003 and the second by Terence O' Rourke Ltd in 2006.

The Ecology Consulting surveys covered the wind farm application area plus a perimeter area of 300m around it. Five survey visits were undertaken during May, June and July 2003 using territory mapping methods employed in the BTO's Common Bird Census (CBC), Marchant, (1983). A supplementary survey of a barn where barn owl pellets had previously been found was carried out in spring 2004 to determine if breeding was likely to occur. Species considered to be breeding within the survey area (numbers of territorial birds are included in brackets) included shelduck (2), buzzard (1), skylark (16), lesser whitethroat (3), linnet (6) and yellowhammer (1). Nightingale was not recorded within the survey area, although three pairs are known to have held territory in scrub in close proximity to the power station from the annual British Energy work. Barn owl was not recorded breeding in the barn that was surveyed. It was considered that the structure was used as an occasional roost and had no potential to support breeding owls.

Terence O' Rourke undertook a ten visit CBC between March and July 2006. This survey work included eight morning and two afternoon visits and covered the wind farm application area only (1.3km^2). Nightingale and lesser whitethroat were not recorded holding territory in the survey area (which did not take in favoured scrub and woodland habitats), but species that were present included skylark (30), song thrush (2), linnet (5) and yellowhammer (1). The density of skylark recorded within the survey area during this study was far higher than during the Ecology Consulting surveys (which covered a larger area). It would therefore seem likely that either the survey results were interpreted differently or that numbers of territorial skylarks in the area fluctuate markedly between years. There is no evidence in the text of the document to suggest that management of the arable fields within the area surveyed might have changed appreciably between the two surveys (e.g. fields might have been put into set aside) which could account for the apparent differences.

In addition to the CBC, Terence O' Rourke undertook a barn owl survey of the four barns and all mature trees within the wind farm application area. This work recorded some old owl pellets, indicating an occasional roost in two of the barns, as well as a dead barn owl (cause of death was not established). It was concluded that the barns did not and were unlikely to be capable of supporting breeding barn owl and that there were no trees in the area with suitable cavities that could accommodate breeding owls.

Field Surveys and Vantage Point Surveys

In order to provide baseline information on the migratory bird interest of the proposed wind farm site, three phases of bird survey were undertaken between 2003 and 2006 inclusive (phases 1 and 2 by Ecology Consulting and phase 3 by Terence O' Rourke Ltd):

- The first phase of survey work undertaken between October 2003 and March 2004, involved 12 visits to record all waders, wildfowl, birds of prey, large flocks or notable species in fields and intertidal habitat within or close to the proposed wind farm site (referred to here as the winter bird study area). In addition, flight observations were carried out from a vantage point over-looking the proposed wind farm site;
- The second phase of survey work also involved counts of target species in fields and intertidal habitat within the winter bird study area, and vantage point surveys from two locations, with 18 visits undertaken between August 2004 and May 2005;
- The third phase of survey work involved field surveys only, with six visits undertaken in March 2006.

The winter bird study area for the wind farm and the SSA for the new nuclear power station are shown on **Figure 3.2**. An overview of the main findings from the wind farm surveys is provided below. The peak counts for waders, wildfowl and other notable species for each of the three phases of fieldwork are presented in Table 3.3.

Table 3.3 Peak Counts during Each Phase of Surveys Undertaken for the Proposed West Hinkley Wind Farm

Species		Phase 1 (2003/04)[21]	Phase 2 (2004/05)[22]	Phase 3 (2006)[23]
Shelduck	*Tadorna tadorna*	421 (9)	450 (7)	104 (6)
Wigeon	*Anas Penelope*	64 (8)	102 (4)	124 (6)
Teal	*Anas crecca*	6 (2)	2 (1)	50 (5)
Mallard	*Anas platyrhynchos*	32 (9)	3 (3)	19 (6)
Pintail	*Anas acuta*	182 (1)	0	70 (5)
Shoveler	*Anas clypeata*	0	0	21 (3)
Common Scoter	*Melanitta nigra*	0	0	2 (2)
Cormorant	*Phalacrocorax carbo*	8 (3)	2 (5)	1 (3)
Little Egret	*Egretta garzetta*	3 (9)	6 (3)	6 (6)
Grey Heron	*Ardea cinerea*	3 (6)	2 (6)	2 (4)
Merlin	*Falco columbarius*	0	0	1 (3)
Peregrine	*Falco peregrinus*	2 (4)	1 (2)	1 (3)
Oystercatcher	*Haematopus ostralegus*	45 (11)	81 (7)	50 (6)
Ringed Plover	*Charadrius hiaticula*	22 (2)	23 (2)	1 (1)
Golden Plover	*Pluvialis apricaria*	0	189 (1)	332 (2)
Grey Plover	*Pluvialis squatarola*	0	0	1 (1)
Lapwing	*Vanellus vanellus*	30 (3)	105 (2)	106 (1)
Knot	*Calidris canutus*	0	0	2 (1)
Purple Sandpiper	*Calidris maritime*	25 (1)	0	0
Dunlin	*Calidris alpine*	1 (1)	0	0
Black-tailed Godwit	*Limosa limosa*	1 (1)	0	1 (1)
Curlew	*Numenius arquata*	22 (12)	37 (7)	70 (6)
Redshank	*Tringa tetanus*	0	1 (1)	5 (1)
Turnstone	*Arenaria interpres*	22 (3)	5 (5)	14 (1)
Black-headed Gull	*Chroicocephalus ridibundus*	101 (12)	P	63 (4)
Common Gull	*Larus canus*	332 (7)	P	15 (4)

[21] Number in parenthesis denotes the number of visits (out of 12) that the species was recorded between 20 October 2003 and 29 March 2004. Approximately two surveys were undertaken in each month.

[22] Number in parenthesis denotes the number of months (out of 9) that the species was recorded between September 2004 and March 2005 inclusive. Approximately, two survey visits were undertaken in each month.

[23] Number in parenthesis denotes the number of visits (out of 6) that the species was recorded between 1-28 March 2006 inclusive.

Species		Phase 1 (2003/04)[21]	Phase 2 (2004/05)[22]	Phase 3 (2006)[23]
Lesser Black-backed Gull	*Larus fuscus*	133 (6)	P	72 (6)
Herring Gull	*Larus argentatus*	205 (12)	P	944 (6)
Great Black-backed Gull	*Larus marinus*	7 (9)	P	8 (5)
Kingfisher	*Alcedo atthis*	1 (2)	0	0
Fieldfare	*Turdus pilaris*	50 (n/a)	45 (1)	
Redwing	*Turdus iliacus*	40 (n/a)	15 (1)	
Raven	*Corvus corax*	2 (4)	4 (3)	
Starling	*Sturnus vulgaris*		2180 (6)	

NB: blank cells do not indicate that the species was not recorded during that phase of surveys, rather that data was not provided for that species, and it is unclear whether it was present or not. P denotes that the species was recorded but no count was undertaken / made available.

Waterfowl

Shelduck were recorded during all three phases of the wind farm survey (2003-06). The intertidal area to the east of the Power Stations supported the largest concentration of foraging birds, particularly the western part of Stert Flats, with the largest numbers recorded around low tide. Small numbers of shelduck were also recorded in 2006 (there were very few records in 2003/04) on the foreshore to the west of the built power station, with numbers generally in the range of 1-15 birds.

Teal were recorded infrequently during the 2003/04 and 2004/05 winter bird surveys but were seen in larger numbers in March 2006. Flocks of 20-50 teal favoured the area around the outfall at Hinkley Point and the open mudflats to the east of this. Movements of small numbers of teal were noted between these intertidal areas and the pools to the south of the Power Stations within Hinkley Point CWS. Shoveler were not recorded during the 2003/04 or 2004/05 winter bird surveys but small numbers including counts of 11 and 21 birds were recorded with teal around the outfall and on the Hinkley Point CWS ponds in 2006.

A count of 182 pintail was recorded on 20 October 2003, but none were recorded during the 2004/05 surveys. During March 2006, a small flock of foraging pintail was present on mudflats to the east of Hinkley Point at low water (mean count 22 birds, peak count 70 birds). No pintail were observed to the west of the operational power stations during any of the winter bird survey work. Wigeon were recorded regularly in all three phases of the survey work, with birds concentrated around the warm water outfall towards the edge of Stert Flats and on the nearby open mud.

Of the other species of waterfowl recorded during the survey period, small numbers of mallard were regularly noted throughout the survey period and 1-2 common scoter were noted offshore on two dates in March 2006. Overall, shelduck, wigeon and mallard made regular use of the winter bird study area throughout the survey period (2003-06), with teal, pintail and shoveler regular only in March 2006 and absent or irregular during the first and second phases of surveys. Shelduck, wigeon and mallard predominantly made use of the intertidal habitat to the east of the plant.

Waders

Curlew and oystercatcher were recorded feeding along the much of the shoreline within the winter bird study area during all three phases of the wind farm survey work. Small numbers of curlew were occasionally recorded in fields close to the shoreline, although there was no evidence of regular use of fields to the west of the built plant for foraging or loafing. Golden plover and lapwing were recorded infrequently during the survey period, although relatively large numbers (332 and 106 birds respectively) of both species were noted during cold weather conditions in March 2006. These counts comprised flocks of lapwing foraging on pasture on Wick Moor, whilst the golden plover were on arable fields to the west of the built plant. Flocks of lapwing (105) and golden plover (189) were recorded in December 2004 and February 2005 respectively[24].

Turnstones were rather irregular in occurrence during the survey period, although a flock of 22 birds was noted on intertidal habitat in front of the built plant on 27 December 2003. A flock of 25 purple sandpipers was also recorded on rocks in front of the built nuclear plant on 27 December 2003 but the species was not recorded subsequently during the survey period. Ringed plover grey plover, black-tailed godwit, dunlin, knot and redshank all made low level use of intertidal habitat within the Winter Bird Study Area during the survey period, being recorded infrequently and in small numbers in the intertidal habitat (see Table 3.3).

Other Species

Up to six little egrets were recorded on at least 19 survey visits throughout the survey period (2003-06). One or two little egrets were frequently recorded feeding in the network of ditches on Wick Moor to the south of the Power Stations, and elsewhere lone birds were occasionally noted on intertidal habitat and pasture to the west of Knighton. Up to three grey heron were recorded on at least 17 survey visits throughout the survey period, and 1-2 loafing cormorants were a frequently recorded on the intertidal habitat within the winter bird study area.

Peregrine were noted on at least nine survey visits[25], particularly around the Power Stations, with the area being used by at least two wintering birds during the survey period (2003-06). Merlin was recorded on three survey visits (around Wick Moor to the south and south-east of the operational power station in March 2006) but not at any other time during the survey period.

Large numbers of herring gulls were recorded around the Power Stations, with birds using the outfall to bathe and drink around low water. A noticeable movement of herring gulls inland from the Bristol Channel during early morning and back again in the evening was noted. Small numbers of great black-backed gull and lesser black-backed gull were recorded during the majority of survey during 2003/04 and in March 2006, the former primarily comprised of immature birds (no data was available for these species for 2004/05). There was one record of a

---

[24] Subjective terms such as ‘small’ or ‘large’ numbers,’ ‘regular’ and ‘irregular’ and ‘reasonably frequent’ occurrence have been taken directly from the wind farm ES. Exact numbers of birds have not been provided within the ES, which leaves little alternative but to adopt this nomenclature when reporting results.

[25] It is also not possible to say exactly how many survey visits individual bird species were recorded on, as only peak counts per month are provided in the ES.

relatively large number of common gulls: 332 birds on 9 November 2003. Kingfishers were recorded on two survey visits during the first phase of surveys in 2003/04 but not subsequently.

Spring Migratory Bird Survey

Surveys were also undertaken by Terence O' Rourke on seven days between 19 April 2006 and 17 May 2006 inclusive. These surveys covered all areas of open coast up to approximately 2km east and west of the proposed wind farm. In addition, fields surrounding the proposed wind farm were also surveyed. The field survey area extended approximately 3km to the south-west, 1km to the south and 1.5-2km to the east and south-east of the proposed wind farm. Although there is no detailed methodology set out in the West Hinkley Wind Farm Environmental Statement it seems likely that instantaneous counts were made of birds using areas of open shore and agricultural fields from a series of local vantage-points and by walking transects through the survey area. This is consistent with earlier winter survey work undertaken by Ecology Consulting as part of the same application.

The commonest species recorded by Terence O' Rourke was herring gull, with 135-383 birds present during each survey visit. Herring gulls favoured the open coast, where they mixed with smaller numbers of lesser black-backed gull, but were also recorded commuting inland and flocking in some areas of farmland, such as on Wick Moor. The surveys recorded small numbers of little egret (4-6) using the rock platforms and gullies off the built nuclear facility and the intertidal creeks to the east of it. Wildfowl included maximum counts of 8 mallard, 4 shoveler, 10 pintail and 2 wigeon in the intertidal zone and inshore waters. Shelduck was recorded with regularity along most sectors of the coast, with counts of 30-110 birds during surveys in April 2006 and 36-84 birds in May 2006. A range of wader species were also noted during this work of which oystercatcher, curlew and whimbrel were the most consistently recorded. The peak count of oystercatcher was of 82 birds roosting on the foreshore at the western end of the existing power station on 17 May. Small numbers of curlew (1-2 birds) were generally recorded during each survey, while whimbrel numbers peaked on 9 May, with 18 birds recorded, and 1-10 birds present on an additional five (of six) survey days. Within the survey area, whimbrel appeared to favour the mudflats on the western edge of Stert Bay, and also used the area of intertidal rock at the western end of the built nuclear power station.

3.2.3 Breeding Birds (British Energy Sources)

Successive British Energy Conservation Wardens have undertaken breeding bird surveys of scrub and woodland habitats to the south and west of the built nuclear power stations at Hinkley on an annual basis since 2000, and the results of these are included in the annual land management review (British Energy/ADAS 1999-2007). Prior to the initiation of annual surveys, ornithological survey work had been conducted sporadically, (e.g. Robins 1986, Somerset Ecological Consultants 1993). Annual surveys are undertaken in two areas of woodland and two areas of scrub; Seaberton Brake (referred to by successive site wardens as site 1); Branland Copse (site 2), scrub near Pixies Pond (site 3) and an unnamed triangular area of scrub (site 4). Surveys are conducted using CBC methodology (Marchant, 1983). The annual survey area is shown on **Figure 3.3**.

The number and diversity of breeding species within the area surveyed by the warden varies between years. In 2004, 35 species were considered to have bred, which is the highest total to date. The commonest species in these annual monitoring plots are generalist species with relatively wide ranging habitat preferences such as blue tit, blackbird, chaffinch and greenfinch. Some species that also favour scrub and woodland edge habitats such as chiffchaff, blackcap and bullfinch are also well represented. The features of the bird community of greatest interest from a national and regional perspective are lesser whitethroat, which is close to the western limit of its national breeding range (Ballance, 2006), and nightingale, which has a restricted national distribution. Nightingale numbers fluctuate, with a maximum of six territories in 1998 (five in 2005, four in 2004 and three in 2003, 2002 and 2000[26]). One pair of lesser whitethroats (occasionally two pairs) consistently breeds in scrub within the annually monitored area and black redstart, which is protected under Schedule 1 of the Wildlife and Countryside Act, bred within the built power station in 1996.

During the 2008 ADAS breeding bird surveys, two territories of nightingale and lesser whitethroat were recorded in site 4. These results were not markedly different to those of the 2007 Entec surveys, for the same species within the same area. The locations of the two nightingale territories recorded in 2008 were very similar to those identified during the 2007 Entec breeding bird surveys (both within the SSA). The two lesser whitethroat territories recorded in 2008 were in a similar location to one of the territories found in the 2007 Entec surveys (all within the SSA).

This annual monitoring work undertaken by the site warden built on baseline surveys of the same woodland and scrub habitats undertaken by Somerset Ecology Consultants (SEC) in 1992 and 1993 (SEC, 1993). These surveys were also undertaken to CBC methodology, and (in 1992) ran in conjunction with a ringing programme. Six nightingale territories were recorded in 2002 and three in 2003. Two lesser whitethroat territories were recorded in 2002. Willow and marsh tit, which are red listed species of conservation concern (Gregory et al., 2002), were recorded as breeding species during the work. Willow tit is on the verge of extinction at county level, while marsh tit is uncommon (Ballance, 2006). Neither species appears to have been recorded breeding in the area since this time[27]. The report by SEC has little interpretation or discussion of results and some data errors and these combined with the fact that it is now rather outdated, indicate it is not considered a key document for informing the baseline.

Robins (1986) conducted a CBC of the whole of the land now considered as the SSA, plus a perimeter zone of approximately 500m to the west and south and 1km to the east in connection with the original Hinkley C Station proposal. Nine survey visits were undertaken between 25 March and 30 May 1985. The commonest species recorded were those with wide ranging habitat preferences such as chaffinch, wren, blackbird, dunnock and woodpigeon. Features of the bird community at that time were nightingale, with six territories located (five in woodland and one in scrub[28]) and lesser whitethroat, with nine territories (eight of which were in hedgerow and one in scrub). Farmland birds included 1 pair of corn bunting, which is now extinct as a breeding species in Somerset (Ballance, 2006), and a number of red-listed species of conservation concern (Gregory *et al.*, 2002) since included on the Section 41 (NERC Act) list including grasshopper warbler (1), bullfinch (2), spotted flycatcher (3), song thrush (4), grey partridge (5), yellowhammer (7) and starling (10). Skylark was present at low density in the

[26] Although both 3 and 6 pairs are quoted for 2000 depending on the source that is referenced.

[27] Marsh tit continue to occur on an occasional basis. E.g. 2 birds were ringed in this area in autumn 2009 (Owain Gabb, pers comm.).

[28] Two in Branland Copse and one each in Whitewall Brake, Seaberton Brake, scrub south of Power Station and Haysgrove Brake.

agricultural fields[29]. Reed warbler, which is now common in wetland habitats throughout the area, was not recorded during the work.

Robins (1986) also noted that barn owl was regularly recorded hunting over the survey area and had formerly nested in a barn at ST208 456. This barn is still extant and accessible to barn owl, and a couple of old pellets found during a preliminary site visit in 2007 suggest an occasional roost site. There is little opportunity for owls to currently nest in this location however, as there is no roof space or appropriate box or recess that would allow them to do so.

3.2.4 Other Information

No novel bird survey work was conducted in preparation for the Environmental Statement for the decommissioning of the Hinkley A Station. Some ornithological information has been received from the Somerset Environmental Records Centre (SERC) relating to bird sightings within 3km of the proposed build area, but many records are not contemporary and lack behavioural context, hence are of limited value and are not summarised here.

3.3 Breeding Bird Surveys

The survey programme resulted in 45[30] species of breeding bird being recorded across an area approximately 4.6km^2 in extent. The location of breeding territories is shown in **Figure 3.4 and Figures 3.4(a-e)**. A key indicating the species that each code refers to is also provided. It should be remembered when considering the figures that the two letter registrations refer to the apparent centre of territorial activity rather than nest sites. It should also be noted that the aim of this survey was to characterise the bird community rather than derive exact densities, which would require a considerably more involved survey programme and is not necessary to inform an EIA. It is inevitable that the densities of some mobile, vocal species have therefore been overestimated due to the precautionary approach that has been taken in interpreting the data, where peak counts of apparently territorial birds have been used to derive densities. Where potential overestimation is considered likely this is acknowledged in the text.

The results of the surveys are presented in Table 3.4.

[29] 12 pairs were recorded at an overall density of 5.8 per km^2.

[30] It is possible that several additional species bred. Figures for swallow and house martin, which forage regularly over the area, are not included in Table 3.4, as domestic properties and farm buildings were not generally entered or walked around, so no accurate census was possible. Feral pigeon and swift may also breed within these buildings, but were not recorded doing so.

Table 3.4 Numbers of Breeding Bird Territories Recorded in the Survey Area

Species	Number of Territories Recorded in Survey Area	Number of Territories Recorded in SSA	Wildlife and Countryside Act Schedule 1 / Annex 1 of EU birds Directive	UK BAP Priority Species	Birds of Conservation Concern Red List	Birds of Conservation Concern Amber List
Buzzard	1	1				
Pheasant	15	9

Bullfinch	3	2		4	4	
Linnet	20	10		4	4	
Yellowhammer	27	11		4	4	
Reed bunting	13	7		4	4	

* These species can be difficult to accurately census as they are high mobile, vocal and / or have complex breeding ecology. Therefore, it is probable that the number of pairs of each has been overestimated to some extent.

Territory mapping found that the commonest species in the survey area were a mixture of farmland birds and ubiquitous species with wide ranging habitat preferences. The large rookery in Branland Copse (109 nests) within the SSA and a smaller rookery of 12 nests at Wick resulted in rook being the most abundant breeding species in the survey area. Other common species included wren, whitethroat, chaffinch, robin and dunnock which bred in the woodland, scrub and hedgerow habitats throughout the survey area. The commonest species (other than rook) with a strong association with open farmland were skylark and yellowhammer.

Skylark was generally sparsely distributed in the survey area, with a notable aggregation of registrations in arable fields to the east and south-east of the SSA. Despite the fact that full access was not possible to this part of the survey area, the network of public footpaths that exists allowed a number of transects to be walked, and the audibility of the species resulted in numerous registrations being plotted. Yellowhammers were mainly found in farmland in the southern and south-western parts of the survey area. Concentrations of breeding records occurred along Wick Moor Drove (the access road for Hinkley A & B) and along a footpath just to the north of Bullen Farm. The mature and extensive hedgerows that occur in these locations, combined with the proximity of arable farmland for foraging provide suitable local breeding conditions for the species.

The density of breeding birds was greatest in the mosaic of scrub and wetland habitats to the south of the built nuclear power stations (outside the SSA). Notable species breeding in this area included four pairs of lesser whitethroat (two pairs were recorded during the Entec surveys and an additional two pairs were recorded by ADAS with a total of seven pairs across the entire survey area), two pairs of nightingale and three pairs of Cetti's warbler[31] as well as red-listed passerines such as bullfinch and linnet. It is acknowledged that nightingale numbers were underestimated during the Entec survey work, as the May territory mapping survey missed the peak song period as a result of bad weather. Complementary survey data collected by ADAS suggests that 4-5 pairs were present in annually surveyed areas (Martin Sage, pers comm.). In total it seems likely that 5-6 pairs were present within the survey area (one of the Entec registrations is likely to be one of the birds recorded by ADAS, but the other registration was out with the annually surveyed area).

Reed warbler occurred in wetland habitats (ditches and reedbed) in the eastern half of the survey area, with the highest density of registrations being around the Sewage Works of the operational plant. Other species with a wetland association such as sedge warbler and reed bunting were also present, but occurred in lower numbers. Grasshopper warbler, which was recorded 'reeling' from ditch-side vegetation on Wick Moor, may have bred, but is more likely to have been a passage migrant given the regional status of this species, the timing of the record and the sub-optimal breeding habitat in which it occurred.

3.4 Intertidal and Inshore Marine Bird Surveys

Intertidal and inshore marine surveys conducted between April 2007 and March 2009 inclusive (the survey period) resulted in a total of 14 species of wildfowl, 17 species of wader, two species of heron, 10 species of gull and tern, and eight additional species of seabird and water bird being recorded. A summary account of use of each count sector by each of the species that appear as cited/designated interest of at least one of the statutory sites within 5km of the SSA is provided below. The peak monthly counts of cited/designated and non-cited/designated species in each count sector are presented in **Tables C1 and C2** respectively in **Appendix C**.

3.4.1 Qualifying/Assemblage Species

Of the species that appear as designated features of the Severn Estuary SPA during either the winter and/or passage periods; shelduck, dunlin and redshank were recorded during the intertidal surveys undertaken at Hinkley between April 2007 and March 2009. In addition, ringed plover, curlew and pintail (which appear in the SPA Review) were also noted. Bewick's swan, white-fronted goose and gadwall (which appear as designated features for their populations of European importance in the Severn Estuary SPA) were not noted during the intertidal surveys. Wigeon, teal, mallard, shoveler, grey plover, lapwing and whimbrel which are listed in the winter assemblage qualification for the SPA were also recorded, but not pochard or tufted duck.

---

[31] Cetti's warbler is the only highly protected species considered to breed within the survey area. It is included on Schedule 1 of the Wildlife and Countryside Act.

Lesser black-backed gull which appears on the Natura 2000 Data Form as a possible future addition to the designated interest of the Severn Estuary Ramsar site during the breeding season was recorded using the survey area during the intertidal surveys (this species has been included in the non-cited species, Section 3.4.2.). In addition, black-tailed godwit, which appears as a cited feature of the Bridgwater Bay SSSI was also recorded.

Shelduck *(Tadorna tadorna)* [SPA, Ramsar and SSSI Qualifying Species]
During the first survey year (April 2007 to March 2008 inclusive), shelduck was recorded on 127 (of 132) intertidal survey dates. The largest numbers were present during August and September 2007, with peak counts of 400 and 700 birds respectively, both in Count Sector 5. In addition, just outside the survey area, counts of 600 and 650 birds were recorded loafing more than 500m offshore from Count Sector 2 on 30 and 21 July 2007 respectively (these counts have been included in **Table C1**). Shelduck were observed in all count sectors, although the largest numbers were recorded in Count Sector 5, both loafing on the water and foraging in the intertidal habitat. The three largest counts of shelduck within the survey area were all of foraging birds in Count Sector 5 (700 birds on 22 September 2007, 530 birds on 6 September 2007 and 400 birds on 23 August 2007). Birds were seen foraging on the intertidal habitat in all count sectors although the vast majority were recorded in Count Sector 5 with very low level use of Count Sectors 1, 2 and 3. Relatively small numbers were seen commuting along the shoreline with no notable movements recorded. Roosting birds were noted on only two occasions, with the largest count being of 13 birds seen 150m offshore on 2 October 2007. Shelduck were recorded throughout the tidal cycle, with the largest numbers recorded foraging in Count Sector 5 approximately two hours either side of low tide. Relatively small numbers were recorded foraging in other count sectors during this part of the tidal cycle. In contrast, numbers of loafing birds were relatively evenly spread across the count sectors and tidal cycle.

During the second survey year (April 2008 to March 2009 inclusive), shelduck was recorded throughout the survey period, being noted on 48 (of 50) intertidal survey dates. The largest flocks were noted during July, August and September 2008, with peak counts of 219 birds feeding in Count Sector 5 on 4 July, 500 birds recorded loafing on the sea in Count Sector 2 on 6 August and 280 birds feeding in Count Sector 5 on 19 September. Numbers in excess of 50 birds were regularly recorded in Count Sector 5 (on 22 occasions) involving birds foraging in intertidal habitat and loafing on the water close inshore. Foraging shelduck were recorded in all count sectors although only regularly in large numbers in Count Sector 5. Foraging activity was concentrated at low tide, with the largest numbers observed three hours either side of low water. In contrast, the largest numbers of loafing shelduck were recorded three hours either side of high water when suitable foraging areas on nearby intertidal habitat were covered by the sea. The numbers of shelduck counted loafing on the sea and on intertidal habitat was more evenly spread across the five count sectors, and not concentrated in Count Sector 5 as for foraging activity. Very few roosting birds were recorded, but included 16 birds in Count Sector 1 on 18 December 2008 and 13 birds in Count Sector 3 on 24 July 2008.

Wigeon (*Anas penelope*) [SPA Assemblage and SSSI Qualifying Species]
During the first survey year (April 2007 to March 2008 inclusive), 2-3 birds were consistently recorded on surveys prior to 12 April 2007 (loafing in Count Sectors 2-5). Wigeon were then recorded on most survey visits from 20 September 2007 to 22 March 2008, with the largest numbers present between November and February inclusive. The three largest counts of wigeon involved 220 birds loafing on the sea close to high tide in Count Sector 4 on 26 January 2008, 170 birds loafing on the sea close to high tide in Count Sector 5 on 15 November 2007 and 150

birds foraging in Count Sector 5 close to low tide on 27 November 2007. Wigeon were observed in all count sectors, although the vast majority (91% of birds) were seen in Count Sectors 4 and 5, most records involving birds loafing on the sea around high tide or foraging on the water close to the tide line. Individuals were also seen feeding on the beach and mudflats, however. Foraging birds were not observed in Count Sectors 1 or 2. Relatively small numbers were seen commuting, usually east along the shoreline with no movements involving large numbers of birds. Roosting birds were noted on only two occasions, including a count of 75 birds on intertidal habitat in Count Sector 4 during high tide on 22 November. The other records of roosting, involved 6 birds on the sea in Count Sector 5 and 27 birds on the sea in Count Sector 3. Wigeon were recorded throughout the tidal cycle with no discernable pattern in numbers of foraging birds, but with larger numbers of loafing birds (usually on the sea) recorded three hours either side of high tide.

During the second survey year (April 2008 to March 2009 inclusive), wigeon were recorded in the intertidal survey area on a total of 24 (of 50) survey dates. Wigeon were noted between 19 September 2008 and 25 March 2009 and were seen on every visit between 23 October and 25 March. The largest numbers were recorded between November and March inclusive, including peak counts of 150 birds foraging in Count Sector 4 on 30 January, 121 birds foraging in Count Sector 4 on 26 February and 110 birds foraging in Count Sector 5 on 12 February. Wigeon were observed loafing on the sea in all count sectors, although the large majority (95% of birds) were seen in Count Sectors 4 and 5. Foraging birds were seen on intertidal habitat and close inshore across much of the tidal cycle in Count Sectors 4 and 5 with no discernable pattern of occurrence. Loafing birds tended to congregate offshore within two hours either side of high water, particularly in Count Sectors 4 and 5. Relatively small numbers were seen commuting, usually east or west along the shoreline with no movements involving large numbers of birds. Roosting birds were noted on two occasions, involving 75 birds in Count Sector 5 on 11 March 2009 and (possibly the same) 75 birds, 1km offshore from Count Sector 1 on the same date.

Teal (*Anas crecca*) [SPA Assemblage and Possible Future Ramsar Site Qualifying Species, SSSI Qualifying Species]

During the first survey year (April 2007 to March 2008 inclusive), teal were recorded irregularly during the survey period. A total of 36 teal were recorded within the intertidal survey area on five occasions as follows: 25 birds on the sea in Count Sector 4 on 27 January 2008, one bird loafing on the sea in Count Sector 2 on 27 February 2008, six birds foraging in Count Sector 4 and three birds loafing on the sea in Count Sector 5 on 2 March 2008 and finally, one bird foraging in Count Sector 5 on 3 March 2008. Teal were not recorded during the second year on intertidal surveys undertaken between April 2008 and March 2009 inclusive. Too few birds were recorded during 2007-09 to identify any patterns in occurrence or use of the intertidal survey area.

Mallard (*Anas platyrhynchos*) [SPA Assemblage Species]

During the first survey year (April 2007 to March 2008 inclusive), mallard were recorded consistently throughout the survey period on 62 (of 132) survey dates, with occurrence being most frequent during January, February and March 2008. Most records involved small numbers of birds, with the largest counts including: 27 birds loafing in Count Sector 5 on 15 June 2007, 20 foraging in the same count sector on 22 June 2007, 17 flushed from the shoreline in Count Sector 5 on 12 February 2008 and 15 birds loafing on the sea in Count Sector 4 on 12 January 2008. Mallard were recorded in all count sectors, with the largest numbers noted in Count Sectors 2, 4 and 5. Most records related to loafing birds and very few mallard were seen roosting, foraging or commuting along the shoreline. Sightings of foraging birds were primarily confined to Count Sectors 4 and 5 and the only records of roosting birds involved a pair in Count Sector 2 on 23 January 2008 and six birds in Count Sector 4 on 24 February 2008.

During the second survey year (April 2008 to March 2009 inclusive), mallard were recorded on 16 (of 50) survey dates in the intertidal survey area: irregularly between April and October but on a more regular basis from November until February. Mallard were recorded in all count sectors, although the majority (93% of birds) were seen foraging or loafing in Count Sectors 4 and 5. The largest counts included 51 birds loafing on the sea in Count Sector 5 on 22 June 2008, 32 birds loafing in Count Sector 4 on 4 July 2008 and 30 birds foraging in Count Sector 5 also on 4 July. However, in general, small numbers of mallard were recorded, with 1-4 birds being seen on most occasions. No roosting mallards were observed, and birds were recorded across much of the tidal cycle with no discernable pattern of occurrence.

Pintail (*Anas acuta*) [SPA Review and Possible Future Qualifying Ramsar Site Species]

During the first survey year (April 2007 to March 2008 inclusive), pintail was recorded on a total of 30 (of 132) survey dates, being present between 4 and 13 April 2007 and 20 September 2007 and 12 March 2008. The three largest counts were of birds loafing on the sea, with 35 birds in Count Sector 4 on 29 October 2007 and 25 birds in Count Sector 5 on 30 October and 16 December 2007. Birds were observed in Count Sectors 2, 3, 4 and 5, although the majority were seen in Count Sectors 4 and 5 (86% of birds). Most records related to birds either loafing on the sea or foraging along the tide-line in Count Sectors 4 and 5. No birds were observed in Count Sector 1 and very few in Count Sectors 2 and 3. Relatively small numbers were seen commuting, usually along the shoreline, with no movements involving large numbers of pintail recorded. Roosting birds were noted on only two occasions, including 12 birds on the water, 150m offshore in Count Sector 5 on 16 December 2007. Pintail were recorded throughout the tidal cycle with the largest numbers of foraging birds occurring three hours either side of low tide in Count Sectors 4 and 5, whereas the majority of loafing birds were recorded on the sea in these count sectors, two hours either side of high tide.

During the second survey year (April 2008 to March 2009 inclusive), pintail were recorded in the intertidal survey area on a regular basis between 19 September 2008 and 19 March 2009 (on 16 of 26 survey dates during this period). Pintail were noted in Count Sectors 3, 4 and 5, with the majority of records (83% of birds) involving individuals loafing or foraging on intertidal habitat or close inshore in Count Sectors 4 and 5. However, the largest count was of 60 pintail loafing in Count Sector 3 on 30 January 2009. No roosting was observed and commuting birds were seen on two occasions, including 40 birds flying east through Count Sector 4 on 30 January 2009. Pintail were recorded across the tidal cycle, although the majority of loafing birds were seen on the sea, two hours either side of high tide and most foraging birds were on intertidal habitat 2-3 hours either side of low water.

Shoveler (*Anas clypeata*) [SPA Assemblage Species]

During the first survey year (April 2007 to March 2008 inclusive), a total of seven shoveler were recorded within the intertidal survey area on four occasions, all in Count Sector 5, as follows: single birds loafing on the sea on 13 February 2008 and commuting offshore on 22 February and 25 February, and 4 loafing birds also on 25 February.

During the second survey year (April 2008 to March 2009 inclusive), a total of five shoveler were recorded on two survey dates as follows: four birds loafing in Count Sector 3 on 11 December 2008 and one bird foraging in Count Sector 5 on 19 March 2009. Too few birds were recorded during 2007-09 to identify any patterns in occurrence or use of the intertidal survey area.

Ringed Plover *(Charadrius hiaticula)* [SPA Review and Possible Future Qualifying Ramsar Site Species]

During the first survey year (April 2007 to March 2008 inclusive), ringed plover was recorded on 37 (of 132) survey dates, and occurred in all months except July. The largest count was of 35 birds commuting east over the sea through Count Sector 2 on 30 October 2007. Birds were observed in all count sectors, although most frequently in Count Sector 1 (48% of birds), with very few birds observed in Count Sectors 3 and 5 (on one date each). Records of foraging birds were almost confined to the beach and rocks in Count Sector 1 with none seen in Count Sectors 3 or 5. Roosting was observed on three occasions, involving 10 birds in Count Sector 4 on 23 September 2007 and 2-3 birds in Count Sector 1 in February and March 2008.

During the second survey year (April 2008 to March 2009 inclusive), ringed plover were recorded in the intertidal survey area in all months of the survey period, and on 27 (of 50) survey dates. The largest count was of 33 birds roosting in Count Sector 1 on 19 September 2007. Ringed plover were recorded in all count sectors, although Count Sectors 1, 2 and 5 received the largest number of records (55%, 22% and 14% of birds respectively). The majority of feeding birds were observed on intertidal habitat in Count Sectors 1 and 2 (76% of birds) with very few seen in Count Sectors 3 and 4 and none in Count Sector 5. Small numbers of ringed plover were observed commuting along the shoreline in all count sectors and roosting was recorded in all but Count Sector 3. Roosting was recorded on eight occasions, five of which were in Count Sector 1 involving 2, 2, 4, 12 and 33 birds respectively. The remaining records of roosting birds were from Counts Sectors 2 (8 birds on 18 December 2008), 4 (1 bird on 5 February 2009) and 5 (4 birds on 27 November 2008). During both survey years, ringed plover were recorded across the tidal cycle with no discernable pattern of occurrence for foraging or loafing birds, although roosting was primarily confined to a period two hours either side of high water.

Grey Plover *(Pluvialis squatarola)* [SPA Assemblage Species]

During the first survey year (April 2007 to March 2008 inclusive), grey plover were recorded on two occasions within the intertidal survey area: a single bird was foraging amongst rocks near the shoreline in Count Sector 2 on 19 December 2007 and three birds roosted in Count Sector 1 on 25 February 2008. Grey plover were not recorded during the intertidal surveys undertaken in the second survey year. Too few birds were recorded during 2007-09 to identify any patterns in occurrence or use of the intertidal survey area.

Lapwing *(Vanellus vanellus)* [SPA Assemblage Species]

During the first survey year (April 2007 to March 2008 inclusive), lapwing were recorded in the intertidal survey area on 18 dates between 19 September 2007 and 12 March 2008 inclusive. Although the species was noted in Count Sectors 1 and 4, all but three sightings came from Count Sector 5. The largest counts were all recorded in Count Sector 5, and included: 40 loafing birds on 23 November 2007; 37 loafing birds on 26 January 2008 and; 36 roosting birds on 22 November 2007. Of the very few foraging birds recorded, all were in Count Sector 5. The only record of roosting birds outside Count Sector 5 involved two lapwings in Count Sector 4 on 15 December 2007. Small groups of 1-4 birds were also seen commuting along the shoreline through Count Sector 5.

During the second survey year (April 2008 to March 2009 inclusive), lapwings were recorded in the intertidal survey area on 7 (of 50) survey dates. Lapwing were seen on 10 July and 18 July 2008, and then on six dates between 7 November 2008 and 16 January 2009. Records were confined to Count Sectors 4 and 5 and foraging birds were only observed on intertidal habitat in Count Sector 5, including 36 birds on 11 December 2008, 18 birds on 11 January 2009 and 45 birds on 16 January. Roosting was recorded on two occasions involving three birds in Count Sector 4 on 18 July 2008 and five birds in Count Sector 5 on 27 November 2008. Too few birds were recorded to identify any detailed patterns of occurrence or use of the intertidal survey area through the tidal cycle.

Dunlin (*Calidris alpina*) [SPA, Ramsar Site and SSSI Qualifying Species]
During the first survey year (April 2007 to March 2008 inclusive), dunlin were recorded on six (of 132) survey dates, as follows: two birds commuting through Count Sector 4 on 24 April and 22 June 2007, seven foraging in Count Sector 1 on 20 July, 13 foraging in Count Sector 2 on 30 July, one foraging in Count Sector 1 on 14 August and two birds commuting through Count Sector 1 on 17 August.

During the second survey year (April 2008 to March 2009 inclusive), small numbers of dunlin (1-9 birds) were recorded on seven (of 50) survey dates. Foraging birds were noted on four occasions, including one bird in Count Sector 1 on 27 June 2008, five birds in Count Sector 1 and another three in Count Sector 2 on 19 September 2008 and nine birds in Count Sector 5 on 24 September. One roosting bird was observed in Count Sector 1 on 23 October 2008. Too few birds were recorded during the intertidal surveys in 2007-09 to identify any clear patterns in occurrence or use of the intertidal survey area. However, the data suggests that dunlin predominantly use the survey area during passage, with very few recorded during winter (one record of two birds commuting through the area on 21 November).

Black-tailed Godwit (*Limosa limosa*) [SSSI Qualifying Species]
During the first survey year (April 2007 to March 2008 inclusive), six black-tailed godwit were recorded commuting west through Count Sector 3 on 13 December 2007. During the second survey year (April 2008 to March 2009 inclusive), black-tailed godwit were recorded in the intertidal survey area on two dates: 15 birds foraging in Count Sector 5 on 27 June 2008 and 100 birds foraging in Count Sector 5 on 21 August 2008. Too few birds were recorded during 2007-09 to identify any detailed pattern of occurrence or use of the intertidal survey area.

Whimbrel *(Numenius phaeopus)* [SPA Assemblage and SSSI Qualifying Species]
During the first survey year (April 2007 to March 2008 inclusive), whimbrel was recorded on 16 (of 132) survey dates. During the spring passage period (primarily April-May), whimbrel were seen on all but one survey date between 24 April and 25 May 2007 inclusive, with a total of 90 birds counted. Birds were recorded in all count sectors, but most frequently in Count Sectors 4 and 5 where 1-5 birds were seen regularly. Foraging birds were recorded in Count Sectors 2-5, with a peak count of 15 birds in Count Sector 5 on 12 May 2007. During autumn passage, whimbrels were noted between 10 and 17 August 2007. All records involved single birds, including individuals commuting through Count Sectors 2 and 5 and foraging birds in Count Sectors 4 and 5.

During the second survey year (April 2008 to March 2009 inclusive), whimbrel was recorded on a total of 12 (of 50) survey dates. During spring passage, a total of 45 birds were counted, with birds recorded on all six visit dates between 9 April and 16 May 2008, with an additional record of two birds on 13 June. During autumn passage, a total of nine birds were recorded on six (of seven) survey dates between 10 July and 21 August 2008. Foraging or loafing whimbrel were observed in all count sectors, with the largest numbers of birds (excluding commuting birds) from Count Sectors 2, 4 and 5 (30%, 27% and 34% of birds respectively). Foraging birds were noted on six occasions, including four birds in Count Sector 5 on 24 April 2008 and three birds also in Count Sector 5 on 9 May. A roosting bird was in Count Sector 4 on 18 July 2008. Whimbrels were recorded across much of the tidal cycle during 2007 and 2008, with foraging in Count Sector 5 primarily taking place during low water.

Curlew *(Numenius arquata)* [SPA Review Qualifying Species, Potential Future Ramsar Qualifying Species]

During the first survey year (April 2007 to March 2008 inclusive), curlew were recorded on all 132 survey visits. The largest counts were of 29 birds roosting in Count Sector 4 on 5 September 2007, 28 roosting there on 15 November and 27 commuting through Count Sector 2 on 22 September. Foraging, roosting and commuting birds were observed in all count sectors. The largest numbers of foraging birds were recorded on the intertidal mud and sand in Count Sector 5 (66% of birds), whilst 61% of roosting birds were noted in Count Sector 4 where a regular high tide roost was identified. Groups of 10-29 roosting birds were recorded regularly two hours either side of high tide in Count Sector 4 from August 2007 to February 2008 inclusive. Small numbers of 1-10 birds were observed commuting either east or west along the shoreline on a regular basis.

During the second survey year (April 2008 to March 2009 inclusive), curlew were recorded on 48 (of 50) survey dates. Numbers were at their lowest during April, May and June 2008 when on average, a total of 7, 2 and 4 birds were recorded on each visit date respectively, compared to 33 in February, 29 in December and 25 in September. The largest counts were all of foraging birds in Count Sector 5 and included 63 birds on 5 February 2009, 34 birds on 23 December 2008 and 31 birds on 11 March 2009. Foraging curlews were observed on a regular basis in all count sectors, with numbers in excess of 15 birds recorded in Count Sector 5 (on eight occasions). Curlews were recorded roosting on 18 occasions, of which 11 were from Count Sector 4, involving up to 20 birds. Elsewhere roosting was much more sporadic, but did include groups of 13 birds on intertidal habitat in Count Sector 1 on 25 March 2009, 17 birds in Count Sector 2 on 19 September 2008 and 16 birds in Count Sector 3 on 16 October 2008. Small numbers of curlew (usually involving 1-20 birds) were also seen on a regular basis commuting along the shoreline in Count Sectors 1, 2 and 3. Curlew were recorded foraging and loafing on intertidal habitat across much of the tidal cycle, although nearly all observations of roosting birds were during the period, 2-3 hours either side of high water.

Redshank *(Tringa totanus)* [SPA and Ramsar Site Qualifying Species]

During the first survey year (April 2007 to March 2008 inclusive), no redshank were seen in the intertidal survey area during spring passage (April and May). During autumn passage and winter, redshank were recorded infrequently and in low numbers, with 16 birds noted on 15 dates between 21 June 2007 and 10 March 2008. One or two birds were seen in all count sectors foraging, roosting, commuting and loafing.

During the second survey year (April 2008 to March 2009 inclusive), redshank were recorded in the intertidal survey area on seven (of 50) survey dates, between 29 August 2008 and 12 February 2009. All but one of the records was from Count Sectors 4 and 5, and involved 1-2 birds. The largest count was of 22 redshanks foraging on intertidal habitat in Count Sector 5 on 11 December 2008. Roosting was observed on one occasion, involving one bird in Count

Sector 4 on 10 October 2008. Too few birds were recorded during 2007-09 to identify any detailed pattern of occurrence or use of the intertidal survey area.

3.4.2 Non-Cited/Designated Species

A range of species that do not appear as cited/designated features of the Severn Estuary Ramsar/SPA or Bridgwater Bay SSSI were recorded during the intertidal surveys undertaken between April 2007 and March 2009 inclusive. A summary account of use of each count sector by each of the species that were recorded on a regular basis in the intertidal survey area is provided below.

Other Waterfowl

A further 13 species of waterfowl that do not appear as specific cited/designated features or within the assemblage qualification of statutory sites (and are not mentioned as potential future interest of the Severn Ramsar Site) within 5km of the SSA were recorded during the survey period. Of these, whooper swan (*Cygnus cygnus*), Canada goose (*Branta canadensis*), red-breasted merganser (*Mergus merganser*), ruddy duck (*Oxyura jamaicensis*), shag (*Phalacrocorax aristotelis*) and great crested grebe (*Podiceps cristatus*) were recorded irregularly in small numbers, each on no more than three occasions during the survey period.

The following species were also recorded during 2007/09:

- Mute swan (*Cygnus olor*). Up to three birds were seen on six dates during 2007-09, including 1-3 loafing birds in Count Sectors 1 and 5;
- Brent goose (*Branta bernicla*). Up to 14 brent geese were seen foraging in Count Sector 5 on three dates during winter 2007/08 (27 January, 13 February and 20 March). This was followed by one brent goose on 24 September 2008, and up to 20 birds foraging or loafing on intertidal habitat in Count Sector 5 on five dates between
11 December 2008 and 11 March 2009;
- Common scoter (*Melanitta nigra*). This species was seen throughout the survey period (2007-09) although in much larger numbers in the first survey year (April 2007 to March 2008). Up to four birds were seen on the sea in Count Sector 4 on three dates in April 2007 and a single bird was also recorded on 21 and 30 July 2007. This was followed by a total of 271 birds on 25 dates between 14 November 2007 and 22 March 2008, with counts of 20-25 birds present during November and December. Many of the records related to birds feeding distantly (i.e. more than 500m) offshore from Count Sectors 4 and 5 which were recorded as incidentals during survey work. However, groups of birds were noted closer inshore on a number of occasions, including 25 feeding 300m offshore in Count Sector 5 on 14 November. During the second survey year (April 2008 to March 2009), up to eight common scoters were seen loafing on the sea on six dates widely spread across the survey period;
- Scaup (*Aythya marila*). A group of four scaup were observed foraging/loafing on the sea in Count Sectors 1 and 2 on four dates between 23 December 2008 and 19 February 2009;

- Grey heron (*Ardea cinerea*). Up to two birds were seen on a regular basis foraging or loafing in all count sectors during 2007-09.

Cormorant and little egret were noted on a more regular basis, further details are provided below.

Cormorant

During the first survey year (April 2007 to March 2008 inclusive), cormorants was recorded on 120 (of 132) survey dates. Birds were seen in all count sectors although most records involved 1-10 birds loafing on intertidal rocks or on the intake tower off Count Sector 3 and approximately 700m north of the SSA (there was a peak count of 15 birds from the sector on 27 October 2007).

During the second survey year (April 2008 to March 2009 inclusive), cormorants were recorded on 41 (of 50) survey dates. Birds were seen in all count sectors, although were only recorded with regularity in Count Sectors 3 and 4. Groups of 1-5 birds were regularly seen loafing or roosting on the intake tower in Count Sector 3, with 12 counted there on 5 December 2008 and 11 on 16 October 2008. Elsewhere, 1-3 birds were regularly observed roosting or loafing on intertidal habitat or commuting along the shoreline in Count Sectors 3 and 4, and less regularly in the other count sectors. Relatively few foraging birds were recorded, with 1-2 birds noted on six occasions on the sea in Count Sectors 3, 4 and 5. During 2007-09, cormorants were recorded in the intertidal survey area throughout the tidal cycle.

Little Egret

During the first survey year (April 2007 to March 2008 inclusive), little egrets were recorded within the intertidal survey area on 105 (of 132) survey dates, and were present on almost every survey between 10 August and 5 December 2007, after which, sightings became less regular. Peak numbers were recorded in August, September and October, with the largest count involving six birds commuting along the shoreline in Count Sector 5 on 20 September 2007. Birds were observed in all count sectors, although Count Sector 4 (29% of birds) and Count Sector 5 (31% of birds) were the most favoured areas, particularly for foraging egrets. Many of the records involved 1-3 little egrets foraging amongst rocks and other intertidal habitat. In addition, 1-2 birds were seen commuting along the shoreline in all count sectors. Roosting birds were noted on only three occasions (involving 1-2 birds in Count Sector 4).

During the second survey year (April 2008 to March 2009 inclusive), little egrets were recorded within the intertidal survey area consistently throughout the period, on 40 (of 50) survey dates. Little egret were observed in all count sectors, with records evenly spread across the different count sectors. The majority of records involved 1-2 birds foraging or loafing on intertidal habitat, or commuting across the survey area (61% of birds were recorded loafing or foraging). Foraging birds were seen across much of the tidal cycle although few were observed one hour either side of high tide (2 individuals) when much of the suitable intertidal feeding areas were covered by water. Few roosting birds were recorded, involving two birds in Count Sectors 2 and 4 on a total of four occasions.

Waders

A further eight species of wader that do not appear as cited/desognated features of statutory sites within 5km of the SSA were recorded during the survey period.

- Golden plover (*Pluvialis apricaria*). One bird was seen alighting briefly in Count Sector 1 on 12 August 2008 before flying south-west;
- Common sandpiper (*Actitis hypoleucos*). In the first survey year, during autumn passage, one bird was seen loafing in Count Sector 5 on 30 July 2007, two in Count Sector 4 on 13 August 2007 and two in Count Sector 5 on 15 August 2007. In the second survey year, a bird was recorded roosting in Count Sector 4 on 21 August 2008;
- Knot (*Calidris canutus*). In the first survey year, knot were recorded on five occasions, including 40 birds flying west through Count Sector 3 on 7 December 2007 and a flock of 100 birds in Count Sector 4 on 19 September 2007. In the second survey year, knot were recorded on two occasions: one bird foraging in Count Sector 1 on 19 September 2008 and another foraging in Count Sector 5 on 5 February 2009;
- Sanderling (*Calidris alba*). A flock of 40 birds was flushed from the shoreline in Count Sector 1 on 8 April 2007. This record was followed by 52 loafing on the shoreline in Count Sector 4 on the following day, and 40 commuting through Count Sector 3 on 11 April. The only other record of this species during 2007-09 was of 6 foraging birds in Count Sector 3 on 30 July 2007; and
- Snipe (*Gallinago gallinago*) were recorded on two occasions, one commuting through Count Sector 5 on 11 December 2008 and another roosting in Count Sector 1 on 18 December 2008.

Oystercatcher, purple sandpiper and turnstone were recorded on a more regular basis. Details are provided below.

Oystercatcher

During the first survey year (April 2007 to March 2008 inclusive), oystercatchers were recorded during all 132 survey visits. The largest counts all involved flocks of roosting birds, with 95 in Count Sector 3 on 29 October 2007 and 89 in Count Sector 1 on 23 September 2007. Roosting birds were observed in all count sectors, with flocks of 20-50 birds recorded regularly in Count Sectors 1, 2, 3 and 4. Flocks of up to 20 birds were also seen on a regular basis foraging and loafing in all count sectors, and commuting birds were frequently observed flying along the shoreline. Groups of 20-50 birds were recorded roosting on a regular basis, two hours either side of high tide in Count Sectors 3 and 4.

During the second survey year (April 2008 to March 2009 inclusive), oystercatchers were recorded in the intertidal survey area on all 50 survey dates. The largest counts were of 100 birds foraging in Count Sector 2 on 18 December 2008, 79 birds roosting in Count Sector 3 on 16 October 2008 and 60 birds roosting in Count Sector 4 on 16 October 2008. Numbers were at their lowest during May and June, but were reasonably constant outside this period (April and July to March). Up to ten oystercatchers were regularly observed foraging on intertidal habitat in all count sectors. Roosting birds were recorded in Count Sectors 1, 2, 3 and 4 but most regularly in Count Sectors 3 and 4, where numbers exceeded 20 birds on five and four occasions respectively and where peak counts of 79 and 60 birds respectively were counted on 16 October 2008. The vast majority of roosting birds (512 of a total of 520 birds) were observed during the period two hours either side of high tide. For foraging and loafing oystercatcher, there was no discernable pattern of occurrence across the tidal cycle.

Purple Sandpiper
During the first survey year (April 2007 to March 2008 inclusive), purple sandpipers were recorded on 16 (of 57) survey dates undertaken between 15 November 2007 and 22 March 2008 inclusive. All but two of the sightings were of loafing birds on the intake tower in Count Sector 3, with the other records being of two birds foraging on rocks in Count Sector 1 on 21 November 2007 and two birds roosting in Count Sector 4 on 15 November 2007. Numbers peaked on 12 January 2008 with a maximum count of 15 birds recorded on the intake tower off Count Sector 3 (after which numbers fell to a peak of seven birds in February and March 2008).

During the second survey year (April 2008 to March 2009 inclusive), purple sandpiper were recorded on five (of six) survey visit dates undertaken between 9 April and 16 May 2008 inclusive, and again on 11 (of 19) visit dates between 14 November 2008 and 25 March 2009 inclusive. Up to nine birds were recorded on 13 dates, loafing, roosting and occasionally foraging on rocks or on the intake tower in Count Sector 3. The remaining observations were all in Count Sector 2, involving seven birds commuting east along the shoreline on 5 February 2009 and single birds foraging and roosting on rocks on 11 December and 18 December 2008 respectively.

Turnstone
During the first survey year (April 2007 to March 2008 inclusive), turnstone was recorded on 48 (of 132) survey dates. Up to eight birds were noted during spring passage (between 4 April and 21 May 2007) with larger numbers recorded during autumn passage and winter (between 16 August 2007 and 22 March 2008). Numbers peaked between January and March, with the highest counts including, 20 birds roosting in Count Sector 1 on 12 March 2008 and 15 foraging birds there on 15 February 2008. Turnstones were recorded in all count sectors, with most sightings relating to 1-10 birds. Small groups of foraging birds were noted on the intertidal shore in Count Sectors 1 and 2 and similarly small groups of roosting and loafing birds were seen in Count Sectors in Count 1, 2 and 4.

During the second survey year (April 2008 to March 2009 inclusive), turnstones were recorded on 30 (of 50) survey dates, between 1 April and 16 May 2008 (spring passage) and between 27 June 2008 and 25 March 2009 (autumn passage and winter). Turnstone were recorded in all count sectors, with the largest counts involving 21 birds foraging in Count Sector 1 on 19 September 2008 and 20 birds roosting in Count Sector 1 on 25 March 2009. Foraging birds were recorded in Count Sectors 1, 2, 3 and 4 but most frequently in Count Sectors 1 and 2 (92% of birds). Roosting and loafing birds were also recorded in all but Count Sector 5, with the majority of records from Count Sectors 1, 2 and 3 and very few from Count Sector 4. Foraging birds were recorded throughout much of the tidal cycle with no discernable pattern of occurrence, although all roosting activity was observed within three hours of high water.

Gulls, Terns and Other Seabirds
Fourteen species of seabirds that do not appear as cited/designated features of statutory sites within 5km of the SSA were recorded during the survey period (many were incidental records from outside the core survey area):

- Manx shearwater (*Puffinus puffinus*). A total of 130 birds were recorded commuting 1-1.5km offshore on 6 July 2007;
- Gannet (*Morus bassanus*). A total of 51 birds were recorded commuting 1-1.5km offshore on three dates between 8 and 13 April 2007;

- Great skua (*Stercorarius skua*). Single birds commuted through the intertidal/ inshore marine survey area on 12 May and 24 September 2007;
- Kittiwake (*Rissa tridactyla*). During the first survey year, kittiwakes were seen on four occasions, with single birds seen flying well offshore on 20 September 2007, 25 November 2007 and 12 March 2008 and five birds on 7 December 2007. During the second survey year, kittiwake was seen on one occasion: a bird commuted west through Count Sector 5 on 22 January 2009;
- Mediterranean gull was recorded on three dates, involving single birds commuting through the intertidal survey area on 30 July 2007, foraging in Count Sector 2 on 23 December 2008 and loafing in Count Sector 5 on 24 September 2008;
- Sandwich tern (*Sterna sandvicensis*). Up to three birds were noted commuting offshore on 12 August 2007 and a total of nine birds commuting through the intertidal survey area on 9 May 2008; and
- Guillemot (*Uria aalge*). One bird was seen offshore on 24 August 2007.

Black-headed, common, herring, lesser black-backed and great black-backed gulls and common and Arctic terns were all recorded on a more frequent basis, details of which are provided below:

Black-Headed Gull

During the first survey year (April 2007 to March 2008 inclusive), black-headed gulls were recorded on 112 (of 132) survey dates, primarily between June and March. Black-headed gulls were predominantly noted in Count Sectors 4 and 5 (where 25% and 54% of birds were recorded respectively). The majority of records were of loafing and foraging birds; groups of up to 50 birds were regularly seen feeding around the outfall in Count Sector 4. Relatively small numbers of birds were seen commuting along the shoreline and no large congregations of roosting birds were located. Roosting birds, when noted, were primarily confined to Count Sectors 4 and 5 although large numbers of loafing birds were observed on intertidal habitat and the sea in all count sectors.

During the second survey year (April 2008 to March 2009 inclusive), black-headed gulls were recorded on 39 (of 50) survey dates in the intertidal survey area between 13 June 2008 and 25 March 2009. Black-headed gulls were recorded foraging and loafing in all count sectors, although the largest numbers were seen in Count Sectors 4 and 5 (32% of birds each). Counts in excess of 100 birds were noted on six occasions, including 120 birds roosting in Count Sector 4 on 21 August 2008, 110 birds loafing in Count Sector 4 on 16 October 2008 and 105 birds on the same date foraging in Count Sector 5.

Common Gull

During the first survey year (April 2007 to March 2008 inclusive), common gulls were recorded on 30 July (one bird) and then in larger numbers on 22 survey dates between 6 September 2007 and 3 March 2008. Sightings were most frequent during December and January. This was the scarcest of the gull species, with most records relating to small numbers of birds commuting along the shoreline and sea. Very few foraging birds were observed and these were confined to the area, in and around the outfall in Count Sector 4.

During the second survey year (April 2008 to March 2009 inclusive), common gulls were recorded on 11 survey dates between 19 September 2008 and 11 March 2009. Most records related to 1-2 birds foraging or loafing on the sea or in intertidal habitat, or commuting along the shoreline or through the inshore waters. Common gulls were noted in all count sectors, with the largest count involved 13 birds loafing in Count Sector 1 on 24 September 2008. Common gulls were recorded throughout much of the tidal cycle during 2007-09 with no discernable pattern of occurrence.

Herring Gull

During the first survey year (April 2007 to March 2008 inclusive), herring gulls were the most abundant species recorded during the intertidal surveys, occurring on all 132 survey dates. The largest count involved 350 birds loafing in Count Sector 3 on 13 March 2008. Large numbers of birds were seen in all count sectors, with a high proportion of the records relating to loafing birds or individuals commuting along the shoreline. Foraging birds were observed in all count sectors, particularly in Count Sectors 1, 3, 4 and 5, usually involving up to 30 birds feeding on the shoreline. Large numbers of herring gulls were seen loafing on rocks, the shoreline and the intake tower, but particularly in and around the Power Stations. Groups of up to 40 herring gulls were recorded loafing in all count sectors on a regular basis. The largest counts of loafing birds were 130, 90, 350, 200 and 48 in Count Sectors 1-5 respectively. No sizeable roosts of herring gulls were identified, with the largest counts of roosting birds involving 120 in Count Sector 3 on 29 October 2007 and 100 in Count Sector 1 on 24 August 2007.

During the second survey year (April 2008 to March 2009 inclusive), herring gull was again the most abundant species recorded during the intertidal surveys, being noted on all 50 survey dates. Counts of 100 or more herring gulls were noted on 20 occasions, with 14 of these coming from Count Sector 3 mostly involving birds loafing on the sea or in intertidal habitat. The largest count, however, was of 276 birds foraging in Count Sector 3 on 15 August 2008. Foraging, loafing and roosting birds were recorded in all counts, with the largest roost count involving 138 birds in Count Sector 3 on 19 February 2009. During the breeding season (April to July 2008 inclusive) foraging and loafing herring gulls were recorded in all count sectors, particularly in Count Sector 3, where a peak of 185 loafing birds was counted on 1 April 2008. Large counts were also noted in Count Sectors 4 and 5, with peak counts of 174 and 111 loafing birds respectively, both on 1 April 2008. Herring gulls were recorded throughout the tidal cycle during 2007-09 with no discernable pattern of occurrence.

Lesser Black-Backed Gull [Possible future Ramsar Site Qualifying Species]

During the first survey year (April 2007 to March 2008 inclusive), lesser black-backed gulls were recorded on 104 (of 132) survey dates. Birds were seen throughout much of the year, although sightings were less frequent and the species was present in smaller numbers between October 2007 and February 2008 inclusive. The peak count was of 50 birds loafing in Count Sector 3 on 13 March 2008. Lesser black-backed gulls were observed in all count sectors with most records relating to loafing birds on intertidal habitat and the sea, or to small groups of birds commuting along the shoreline and sea. Very few foraging or roosting birds were noted.

During the second survey year (April 2008 to March 2009 inclusive), lesser black-backed gulls were recorded on 42 (of 50) survey dates. Birds were recorded in all count sectors although the largest count was of 35 birds loafing in Count Sector 4 on 1 April 2008. The majority of records related to birds loafing on the sea or intertidal habitat, or commuting through the survey area. Relatively few birds were observed foraging or roosting (1-3 birds were noted on ten and five occasions respectively). Counts of ten or more birds were noted on seven occasions, with all but one record involving loafing birds in Count Sectors 3 and 4. During the breeding season (April to July 2008 inclusive), 1-5 foraging and loafing birds were recorded regularly in Count Sectors 3, 4 and 5 but none in Count Sectors 1 and 2. Counts in excess of 10 birds were noted on three occasions (twice in Count Sector 3 and once in Count Sector 4). Lesser black-backed gulls were recorded throughout the tidal cycle with no discernable pattern of occurrence.

Great Black-Backed Gull

During the first survey year (April 2007 to March 2008 inclusive), great black-backed gulls were recorded on 87 (of 132) survey dates through much of the period. Birds were seen in all count sectors, with a large proportion of the records relating to birds loafing on, or commuting along the shoreline and sea. Very few foraging or roosting birds were observed. Small groups of 1-2 birds were frequently seen loafing on the intake tower in Count Sector 3, with a maximum count of 12 birds there on 13 August 2007. Great black-backed gulls were recorded throughout the tidal cycle with no discernable pattern of occurrence.

During the second survey year (April 2008 to March 2009 inclusive), great black-backed gull were recorded on 35 (of 50) survey dates throughout much of the survey period. Birds were observed in all count sectors, with numbers being relatively consistent throughout. The majority of records were of 1-2 birds loafing on intertidal habitat or the sea, or commuting through the survey area. Few foraging birds were recorded, with 1-3 birds noted on ten occasions, the majority of which were in Count Sector 5. Great black-backed gulls were recorded throughout the tidal cycle with no discernable pattern of occurrence.

Common and Arctic Terns

During the first survey year (April 2007 to March 2008 inclusive), single common terns were recorded on 6 and 30 July and then occurred in larger numbers on 14 dates between 23 August 2007 and 31 October 2007. The vast majority of records related to groups of birds feeding around the outfall in Count Sector 3 in September and October, with a maximum count of 48 birds noted on 25 September. The pattern of occurrence for Arctic tern was very similar to that of the common tern, with birds recorded on 12 dates between 14 September 2007 and 31 October 2007. The vast majority of records related to groups of birds feeding around the outfall in Count Sector 3 during 14-25 September and 3-6 October, with a maximum count of 38 birds noted on 25 September. In addition, a further 111 unidentified terns, likely to be either Arctic or common terns were recorded between 26 September and 2 October[32]. All of these records related to birds feeding around the outfall, with a maximum count of 35 birds there on 28 September.

During the second survey year (April 2008 to March 2009 inclusive), common terns were recorded on three dates, as follows: 9 May 2008 (two birds loafing in Count Sector 2), 16 May (32 birds commuting east and ten birds foraging offshore in Count Sectors 3 and 4) and 19 September 2008 (four birds foraging offshore in Count Sector 4). Arctic terns were noted on one date, involving five birds foraging offshore in Count Sector 4 on 21 August 2008.

[32] Common and Arctic terns are difficult to identify to species at distance, particularly when they are present in wheeling flocks such as those seen around the outfall. Both juvenile and adult birds show similar plumage characteristics that at distance or in poor light often make reliable separation very problematic.

3.5 Daytime Field Surveys

A wide range of target species (as defined in Section 2.2.2) were recorded in the survey area during the daytime field surveys undertaken between September 2007 and March 2009 inclusive. Table 3.5 shows the peak count[33] for each month within the survey area. **Figure 3.5a-b** shows the location within the survey area of any cited/designated[34] species during the first and second survey years (2007/08 and 2008/09 respectively) and **Figures 3.6a-b** illustrates any notable congregations (i.e. flocks of 50 or more birds) of non-cited/designated, target species[35] recorded within the survey area during 2007/08 and 2008/09 respectively.

---

[33] The peak count has been derived from the sum of all counts within the field survey area on a single survey date.

[34] Cited/designated species - qualifying or assemblage species for statutory sites of nature conservation value within 5km of the site.

[35] Non-cited/designated, target species - species that were targeted during the daytime field surveys (as defined in section 2.2.2), but not cited in statutory sites of nature conservation value within 5km of the site. Flocks of wood pigeon and rook have been excluded because both species are considered to be of limited conservation value.

Table 3.5 Daytime Field Survey Results (Peak Monthly Counts within the Survey Area)

Species[36]		Year	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar

[36] NB: some species (such as mute swan) were recorded in one survey year only. No large counts (i.e. 50 plus birds) of black-headed, common or lesser black-backed gulls were recorded during 2007/08. Large counts of stock dove, pied wagtail, swallow, jackdaw, house sparrow and goldfinch were recorded in one survey year only.

Nine species forming part of the cited/designated of the Severn Estuary SPA and Ramsar Site and/or the Bridgwater Bay SSSI, were recorded during the daytime field surveys, as follows:

- SPA qualifying species: shelduck, gadwall, curlew (SPA Review) and redshank;
- SPA assemblage qualification species: teal, mallard, lapwing and whimbrel;
- Ramsar site qualification species: shelduck, gadwall and redshank;
- Possible future Ramsar site qualification species: teal and lesser black-backed gull; and
- SSSI qualification species: shelduck and whimbrel.

Overall, the survey area was used by relatively small numbers of (mostly) common and widespread species, few of which formed part of the cited/designated interest of locally designated areas. Large flocks of birds were not recorded on a regular basis feeding, loafing or roosting in the fields. Different species were associated with the two dominant habitat types in the survey area: improved grassland and pasture (e.g. lapwing) and arable fields (e.g. curlew), which at the time of the surveys were predominantly ploughed or given over to stubble/set-aside, rape and winter-sown wheat.

3.5.1 Detailed Summary of Results

A summary of the occurrence during the first survey year (September 2007 to March 2008 inclusive) and second survey year (April 2008 to March 2009 inclusive) of those species listed above (i.e. designated or possible future designated features of the Severn Estuary SPA/Ramsar site and/or Bridgwater Bay SSSI) is as follows:

- Shelduck [SPA and Ramsar site qualifying species]. During the first survey year, shelduck were recorded on two survey dates: 2-3 birds feeding in Field 1 on 11 and 14 March 2008. During the second survey year, shelduck were recorded on eight survey dates, predominantly involving small groups of birds loafing in fields, including 20 birds in Field 13 on 8 May 2008 and 16 birds in Field 3 on 12 June 2008. There was one record of foraging shelduck, involving 4 birds in Field 2 on 22 December 2008;
- Gadwall [SPA and Ramsar site qualifying species]. One bird was on the pool east of the sewage works on 22 December 2007;
- Teal [SPA assemblage and possible future Ramsar site qualifying species, SSSI qualifying species]. During the first survey year, teal were recorded from 19 November 2007 onwards, particularly on the pool to the east of the sewage works, where a maximum of 70 birds were observed on 15 January 2008 and 40 birds were present on 25 January 2008. Elsewhere, up to six teal were seen in ditches to the south of the Power Stations. During the second survey year, teal were regular visitors to the pool, east of the sewage works between September 2008 and February 2009 although were rarely seen elsewhere. Counts in excess of 20 birds were recorded on the pool on ten dates, with a peak of 110 birds noted on 21 January 2009 and 70 birds on 6 and 18 February 2009;

- Mallard [SPA assemblage species]. Small numbers (usually 1-10 birds) were seen on a regular basis on the pool east of the sewage works and in ditches around Wick Moor, in the east of the survey area;
- Lapwing [SPA assemblage species]. During the first survey year, lapwing were recorded on a regular basis, with most records of foraging birds being on pasture and arable fields south of the Power Stations, in the east of the survey area. Flocks in excess of 50 lapwings were recorded on four occasions foraging on pasture and fields containing winter-sown cereal in the south and south-east of the survey area. Maximum counts of feeding birds included 67 in Field 48 on 16 November 2007. During the second survey year, small flocks of foraging lapwing were noted on 24 occasions (on 17 dates). On 10 January 2009, a total of 125 birds were counted across a number of coastal fields to the west of the built plant (within the likely build area). Flocks of foraging lapwing were recorded on a regular basis (on 14 survey dates) particularly between October and February, primarily in fields of pasture to the south of the Power Stations around Wick Moor (outside the likely build area), and in fields immediately to the south of the SSA (within the likely build area);
- Curlew [SPA Review qualifying species, potential future Ramsar qualifying species]. During the first survey year, all but five of the 15 records of curlew came from large arable fields adjacent to the seawall to the west of the built plant, including four records of 1-10 foraging birds in Fields 1 and 2 and six records of 1-14 foraging birds in Field 17 immediately to the west of it. Elsewhere, records of curlew were very sporadic but included 21 birds at Wick Moor (Field 81) on 21 December 2007. During the second survey year, curlew were recorded on a more regular basis (on 26 occasions) with most records involving 1-15 birds foraging in Fields 1 and 2 (October to March) and Fields 17 and 39 (September to January). The peak count was of 20 curlew foraging in Field 17 on 21 January 2009;
- Whimbrel [SPA assemblage and SSSI qualifying species] was recorded on one survey date involving three birds loafing in Field 2 on 8 May 2008;
- Redshank [SPA and Ramsar site qualifying species] were recorded on one survey date, involving a bird in Field 16 on 10 January 2009.

Non-cited/designated species recorded in the SSA during the daytime field surveys included waders, raptors and farmland passerines. A summary of the more notable activity for the entire survey period (September 2007-March 2009 inclusive) is included below:

- Little egret. During the first survey year, 1-2 little egrets were regularly seen in the ditches in and around Wick Moor. Little egrets were seen on 13 occasions during November 2007 to March 2008 inclusive, with most sightings being of single birds loafing or foraging in ditches and on pastures immediately south of the Power Stations. Little egrets were also occasionally seen in fields north of Myrtle Farm in Shurton. During the second survey year, little egrets were regularly seen foraging around Field 92 (Wick Moor) where a peak count of eight birds were feeding on 22 October 2008 (8 birds were also noted commuting through this field on 4 December 2008);

- Golden plover. During the first survey year, records of foraging golden plover were infrequent (up to seven birds recorded on a total of three survey dates in December 2007 and February 2008) and confined to coastal fields of winter-sown cereal in the western part of the survey area. During the second survey year, flocks of golden plover were noted on 17 occasions between January and March 2009: including 30 birds foraging in Field 26 on 10 January, and regular small flocks in Fields 37 and 48. The vast majority of golden plover were seen on two dates, with a total of 98 and 127 birds recorded primarily in two areas (Field 17 and Fields 31/37/48) on 6 and 7 February 2009 respectively;

- Snipe. Small numbers of snipe (usually 1-3 birds) were recorded regularly in both winters between November and February in fields and ditches on Wick Moor to the south of the Power Station. Twenty snipe in Field 13 on 10 January 2008 and ten birds loafing in Field 37 on 11 December 2007 were the most notable counts;

- Notable raptors. During the first survey year, single hunting or commuting merlins were recorded on five occasions, and peregrine on nine occasions within the survey area. The records suggest that up to two peregrines were using the survey area during the 2007/08 winter period; they were most often noted in and around the immediate vicinity of the power stations. During the second survey year, a minimum of two peregrine were regularly recorded hunting in the survey area throughout the survey period. These birds showed a clear association with the operational plant, but are not considered to have bred (Dick Best, British Energy Warden, *pers comm*). Also during the second survey year, there were six winter records of merlin, a marsh harrier was noted commuting through the area on 14 August and hobby was seen on 20 May and 9 July 2008;

- Lesser black-backed gull [Possible future Ramsar site qualifying species]. The only record of note was of ten birds foraging in Field 56 on 8 May 2008;

- Other gull species. During the first survey year, very few large flocks of gulls were seen within the survey area. During the second survey year, counts of 50 or more black-headed gulls were recorded on four occasions, all in autumn and winter. Large numbers of common gull were not recorded although considerable numbers of herring gulls were frequently recorded foraging or loafing in the fields throughout the survey period. Counts in excess of 100 herring gulls were noted on five occasions, including 300 foraging birds in Field 78 on 20 November 2008 and 170 loafing birds in Field 48 on 14 August 2008. During the breeding season, large counts of herring gull were recorded infrequently, but included a peak count of 50 foraging birds in Field 56 on 8 May 2008;

- Kingfisher. During the first survey year, single kingfishers were seen or heard on four occasions between December 2007 and March 2008 inclusive, all along water-filled ditches south of the Power Stations. During the second survey year, single birds were recorded in ditches in and around Wick Moor on 22 and 30 October and 6 February;

- Cetti's warblers were heard on a regular basis throughout the survey period (2007-09) in the mosaic of habitats to the south of the power station, usually calling or singing from reedy ditches forming the boundaries of fields 66 and 89 and in scrub near the Sewage Works;

- Winter farmland passerines (2007/08). During the first survey year, flocks of wintering skylark and linnet were associated with the large arable fields in the west of the survey area. Peak counts of linnet in this area included: 250 birds in Field 1 on 21 September 2007 and 80 in Field 17 on 19 November 2007. Peak counts of skylark included: 120 birds in Field 1 on 21 December 2007 and 10 January 2008 and up to 150 birds in Field 17 on four occasions in January 2008. Seventy linnets were also recorded in Field 80 in the south-east corner of the survey area on 16 November 2007, and a flock of 25-30 yellowhammers was recorded on two occasions in Field 46, north of Myrtle Farm in the south of the survey area. Meadow pipit numbers were highest between January and March 2008, with a peak count of 95 birds foraging on pasture (Field 84) on 17 March. Flocks of 35-95 meadow pipits were recorded in pastures in or near North Moor on five occasions. This species was widespread, although most of the larger counts were on pasture in the east of the survey area. Foraging starlings were usually associated with pasture and included flocks of 100-600 birds on five occasions in winter 2007/08 and 15 occasions in winter 2008/09, usually in fields around Wick Moor;

- Winter farmland passerines (2008/09). During the second survey year, skylarks were recorded widely across the survey area, with the largest numbers again seen in arable fields in the western part of the survey area, with a total of 600-700 birds counted in fields 17, 21, 22, 23, 27 and 28 on 7 February 2009 and 300 birds in this area on 11 February. Flocks of 30-80 linnets were seen foraging in fields on a regular basis during August to March inclusive, with the more notable counts being 80 birds in Fields 14 and 15 on 14 August 2008, 70 birds in Fields 16 and 17 on 20 November 2008 and 140 birds in Field 17 on 15 November 2008. Linnet flocks were particularly frequent in Field 17;

- Winter thrushes. Large flocks of wintering thrushes were occasionally observed feeding in fields within the SSA. Flocks included: 300 fieldfares in Field 65 on 20 November 2007 and 110 redwings in Field 45 during 6-7 February 2008. During the second survey year, flocks of 100-300 redwings and fieldfares were noted on four survey dates (20 November 2008 and on three dates in February 2009);

- Additional species of interest included: up to two water rails on 6-7 February 2008 in typical wetland habitat to the south of the built plant; a black redstart along the seawall near Hinkley Bridge on 22 December 2007, and a firecrest (presumably a migrant bird) in the hedge by Fields 32/30 on 18 March 2008.

3.6 Nocturnal Field Surveys

Results from the nocturnal surveys undertaken within the survey area in 2007-09 provide no evidence to suggest that the fields or adjacent upper intertidal habitat were being used by large numbers of roosting or foraging birds at night. Due to the limitations of even the most sensitive of night vision equipment, and the difficulties in locating small waders hidden in tidal creeks at night, the counts obtained from the intertidal survey are indicative, as is behaviour assigned to all of the species recorded during the survey work. Nevertheless, the consistency of the results and the experience of the surveyor in undertaking nocturnal work in Somerset (on behalf of

Natural England and others) gave considerable confidence that the results are an accurate reflection of the level of interest present.

Table 3.6 and Table 3.7 show the total number of each species recorded on each visit during the first and second survey years respectively, and **Figure 3.7a-b** shows the location and numbers of target species recorded in the first and second survey years respectively.

A wide range of target species (as defined in Section 2.2.2) were recorded during the nocturnal surveys, either in fields within the survey area, or on intertidal habitat within the intertidal survey area. The following provides a summary of nocturnal bird activity[37] on the intertidal area adjacent to the SSA during the first survey year (December 2007 to March 2008 inclusive) and second survey year (April-May 2008 and August 2008 to March 2009 inclusive):

- Shelduck. During the first survey year, the only notable count of shelduck as of 19 birds in Count Sector 1 on 24 January 2008. Up to four birds were recorded on a further three survey dates during December 2007 and in January to February 2008. During the second survey year, 20-24 shelduck (two records of loafing birds and the other record of birds being flushed) were noted on three dates (10 and 13 December 2008 and 10 January 2009) also in Count Sector 1. Roosting shelduck were noted on one occasion, involving five birds in Intertidal Count Sector 4 on 21 August 2008;

- Oystercatcher. During the first survey year, oystercatchers were recorded on five survey dates between December 2007 and February 2008. Peak counts of roosting birds in Count Sector 1 included: 100 birds on 24 January 2008 and 65 birds on 21 February 2008. During the second survey year, 20-80 oystercatcher were recorded on 11 dates (all in Intertidal Count Sector 1), including counts of 30-80 roosting birds on ten dates;

- Whimbrel (single calls) was heard in the intertidal area on 14 April 2007 and 14 August 2007;

- Small numbers of wigeon, golden plover, lapwing, redshank, dunlin, snipe and turnstone were noted infrequently during 2007-09;

- Ringed plover, grey plover, turnstone and curlew were noted on a more regular basis (3, 1, 2 and six dates respectively in the first survey year, and 11, 5, 5 and 13 dates respectively in the second survey year).

Nocturnal use of the coastal fields (as opposed to the intertidal covered above) by waders and other target or notable species is summarised as follows:

- Golden plover. During the first survey year, small numbers of golden plover (1-8 birds) were recorded on all nocturnal surveys in arable fields and pasture adjacent or close to the seawall in the west of the survey area (all of which were either in or immediately adjacent to the SSA). The frequency of golden plover records from the nocturnal surveys was appreciably greater than that for the daytime field surveys during 2007/08, indicating that the survey area (including the SSA) was probably being used by small numbers of foraging and/or roosting birds. During

[37] In practice, even with high quality night vision equipment, it is very difficult to assign behaviour to species.

the second survey year, golden plovers were recorded in fields within the survey area on a regular basis (on nine dates), particularly in Fields 17 and 2 (both within the SSA). Peak counts included 21 foraging and loafing golden plover in Field 2 on 10 December 2008 and 13 foraging birds in nearby Field 17 on the same date. The total number of golden plover counted on any one date, rarely exceeded 15 birds, but included 37 birds counted on 10 December 2008 and 19 birds on 10 March 2009;

- Lapwing. During the first survey year, 1-3 lapwings were recorded on a regular basis, primarily in pasture to the south of the Power Stations in the eastern part of the survey area. During the second survey year, lapwing were noted widely across the survey area on eight dates, including 14 birds in Field 60 on 10 January 2009 with an overall total of 55 birds in all fields on that date;

- Snipe. During the first survey year, small numbers of snipe were recorded on all nocturnal survey visits, again in pasture areas, but also along ditches to the south of the Power Stations, with the largest count involving 15 birds in Field 66 on 21 February 2008. Two counts in excess of ten snipe were recorded in the ditch between Fields 66 and 83, also in this area. During the second survey year, snipe (usually 1-3 birds) were flushed from ditches in and around Wick Moor on a total of 13 dates between September 2008 and March 2009. The largest counts of snipe all came from Field 66 (North Moor), and included 12 birds on 10 December 2008, 20 birds on 13 January 2009 and 15 birds on 6 February 2009;

- Other wildfowl. During the first survey year, up to 14 mallard were recorded on four dates between December 2007 and March 2008. Two teal were seen on two dates (January and February 2008), with all but one record of mallard and teal derived from ditches south of the Power Stations. During the second survey year, small numbers of wigeon (1-2 birds on three dates), teal (1-2 birds on three dates) and mallard (up to nine birds on five dates) were also recorded in fields and ditches, again primarily to the south of the Power Station around Wick Moor;

- Barn owls were recorded over Field 85 (part of the Hinkley Nature Reserve) on 17 March 2008 and loafing in Field 7 (within the SSA) on 21 August 2008;

- Woodcock. No woodcock were recorded during the first survey year. During the second survey year, 1-2 woodcock were flushed from Fields 1 and 17 (within the SSA) on four dates during the winter.

Passerine interest included 2-3 singing Cetti’s warblers immediately south of the Power Stations (Fields 60/64/80) and two singing nightingales (in scrub around Field 87 and west of the sewage works) in April and May 2008.

Table 3.6 Nocturnal Field Survey Results, 2007/08[38]

[39] The figures provided show the total number of birds recorded on each visit in fields within the survey area (as used in the daytime field surveys) and on adjacent intertidal habitat. The letter 'P' denotes that the species was present, being seen/heard during the visit, but that no accurate count could be obtained. It should be noted that even with high quality night vision equipment, it is very difficult to obtain an accurate count and therefore the figures shown should be treated as the likely minimum count of individuals present.

4. Discussion

4.1 Breeding Bird Surveys

When considering breeding bird populations, importance is often taken as meaning that a site supports at least 1% of the population under consideration at county (Somerset), national[40] or international level[41]. This 1% of population threshold has also been used as a basis for the evaluation of likely significant effects on European and nationally designated sites of conservation importance, and as such was considered by RSPB to be an appropriate starting point for assessing potential effects of new build on the Severn SPA and Bridgwater Bay SSSI bird populations (Richard Archer, RSPB, pers comm.). The discussion of the 2007 breeding bird surveys at Hinkley takes account of the 1% threshold as well as the ecological characteristics of individual species to determine key ornithological issues and to establish the importance of the area to bird populations. To establish population estimates, thereby providing a basis for evaluation, relevant regional and national accounts (Ballance 2006, Brown & Grice 2005) have been used in conjunction with bird reports, scientific papers and information on population trends available from the BTO website (www.bto.org).

4.1.1 Highly Protected Breeding Species

The three Cetti's warbler territories within the SSA were located in scrub to the south of the built nuclear plant. Cetti's warbler particularly favour the habitat that develops where bramble and willow invades the edge of extensive reedbeds (Brown & Grice, 2005). During the breeding season birds forage on damp, bare ground at the base of scrub thickets or on wet muddy ground produced as a result of fluctuating water levels (Bibby, 1982); they also forage more extensively in reedbeds during the winter (Brown & Grice, 2005). Much of the habitat within the SSA, which predominantly consists of mixed farmland is therefore unsuitable for supporting breeding or wintering Cetti's warbler. The only suitable habitat is to the south of the built plant in the eastern arm of the SSA.

[40] For many breeding species that occur within the survey area there have been English population estimates published by Brown & Grice (2005), and these have been used as a basis to determine thresholds of national importance. These are precautionary, as from a legal perspective Wales and England combined is treated as a national unit - as the basis of protective legislation for breeding birds, the Wildlife and Countryside Act, applies to both countries. For waterfowl, however, information is generally presented by the BTO for Great Britain (GB) rather than England, and the readily available English estimates from other sources are less relevant to Hinkley (as the adjacent Severn SPA covers areas of both Welsh and English coast, and it is reasonable to assume that there is regular interchange between the two countries of some species). GB figures also form the basis on which European Sites are designated under the Habitats Regulations. Therefore, for the discussion of the intertidal data, GB figures are considered to represent 'national' totals.

[41] There is no fundamental biological reason to take 1% of a population as the threshold level for establishing the level of importance of a site. Nevertheless, this percentage is widely considered to be of value in giving an appropriate level of protection to populations, and has gained acceptance on this basis throughout the world. The criterion was, for example, adopted by parties involved in the Ramsar Convention 1971. Thereafter, the 1% level of national species totals has been taken as the basis of assessment in various countries, including Britain (Stroud, Mudge & Pienkowski, 1990).

Cetti's warbler is now considered a fairly common resident breeder in Somerset, despite the fact that breeding was first proven in the county as recently as 1982 (Ballance, 2006). During the national census in 1996 a total of 63-67 territories were found at 20 Somerset sites (Wotton *et al.*, 1998). By 2002 numbers in the Avalon Marshes alone had reached 147 territorial males (Ballance, 2006), while a total of 347 territorial males were submitted for inclusion in the 2005 Somerset Bird Report (Gibbs [Ed], 2006). At the national level the number of territorial males was considered to have more than doubled (from 300 to 622) between 1997 and 2000, and was estimated at 851-878 by 2002 (Ogilvie, 2004). Based on these figures, and assuming a constant rate of increase since this time, the current number of territorial males in England may now be between 1,423 and 1,518 individuals. It is reasonable to suggest, therefore, that the survey area therefore holds a maximum of 0.86% of the regional territorial males and between 0.19 and 0.21% of the national number. It follows that Hinkley is not therefore considered a key breeding site for Cetti's warbler at regional or national level.

4.1.2 Red-Listed Birds of Conservation Concern and UK BAP Priority Species

A total of 10 species featuring on the red-list of birds of conservation concern[42] and/or the UK BAP Priority Species List[43] were recorded breeding within the survey area in 2007. Despite considerable declines at national level, many of these species remain common or abundant at national and regional level, and this is relevant to the majority of the farmland passerines that were recorded breeding within the survey area at Hinkley. A summary of the likely importance of the survey area to each of the breeding red-listed and UK BAP species is given below.

Cuckoo, which is a UK BAP Priority Species (and features on the amber list of Birds of Conservation Concern due to a moderate decline in the breeding population over the past 25 years), was recorded holding territory in the Wick Moor area. Cuckoo is considered to have declined in intensively managed lowland farmland in Somerset (Ballance, 2006), although there have been no county population censuses and there are no long term data sets for the species that enable the scale of decline or the current county population level to be robustly assessed. The association of strong local populations of dunnock and reed warbler, which are both regular host species[44], and the mosaic of semi-natural habitats (likely to be rich in invertebrate prey) to the south of the built power stations provide suitable breeding conditions for cuckoo[45]. Two

---

[42] The background to the establishment of a 'traffic light system' of conservation concern for UK birds is discussed in Gregory *et al*., (2002). 'Red-listed' species include those that are globally threatened, have suffered an historical population decline (between 1800 and 1995) or which have experienced rapid declines in their UK breeding population or contractions in their UK range of more than 50% over the past twenty-five years. Amber listed species have suffered moderate (25-49%) declines in their UK breeding population or range over the past 25 years, have an unfavourable conservation status in Europe (and are therefore of European concern), breed in very low numbers (5 year mean of 1-300 pairs), breed at 10 or fewer UK sites, or occur in relatively high numbers in the UK (exceeding 20% of the European breeding, migratory or non-breeding populations). Other species have 'green' status, as they do not fulfil these criteria. This implies that the population of a species is either stable or increasing or that too little is known about the population to allow the species to be included on the red or amber list.

[43] This is a list of species that are considered to be globally threatened and/or which are rapidly declining in the UK (by more than 50% in the past 25 years). Each has its own UK Species Action Plan (SAP) which identifies environmental measures to address the recent decline in numbers.

[44] Cuckoo is a brood parasite. A review of BTO Nest Record Cards found that dunnock, reed warbler and meadow pipit accounted for over 85% of cuckolded nests between 1939 and 1982 (Glue & Murray, 1984).

[45] Cuckoo has fairly wide ranging habitat preferences, and at national level is commonly recorded breeding in moorland, heathland, farmland, a range of wetland habitats, open woodland, farmland, parks and large suburban

territorial male cuckoos were recorded in the SSA (three in the survey area) during the breeding bird survey in 2007. The number of territorial males that are reported to the Somerset Bird Club on an annual basis (e.g. 339 in 2005) indicates that the survey area is unlikely to be of county importance to the species.

Three bullfinch territories were recorded within the survey area, all within scrub and mature hedgerow to the south of the built power stations. Although there is no census data, both Ballance (2006) and Gibbs ([Ed], 2011) consider bullfinch to be a fairly common resident species in Somerset, albeit one that is perceived to have declined in lowland farmland. It follows that three pairs are unlikely to exceed the threshold of regional importance.

Linnet is also perceived to have declined in Somerset, although there is again relatively little survey data that allows the scale of the decline and the habitats primarily affected to be assessed. The species remains a fairly common breeder in the county, and coastal farmland surveys undertaken in 2000 concluded that 154 pairs were present between the Axe Estuary and Quantoxhead, while 840 pairs were found on Exmoor in 2002 (Ballance, 2006). Of 26 territorial linnets within the survey area at Hinkley, ten were within the SSA, where they favoured coastal scrub and the edges of woodland blocks. Linnet is described as a fairly common resident and migrant breeder in Somerset, with 70-90 pairs in the Quantocks in the 1990s and 360 birds in Exmoor (including Devon) in 1992/3 (Ballance (2006). Given this, and the likely abundance of suitable habitat present in Somerset, the county population is likely to be well in excess of 1,000 pairs. In view of this, the population in the SSA is considered to be of no more than local importance.

Yellowhammer and reed bunting are both locally common breeding species in Somerset, with the former occurring in arable farmland with established hedgerows and in heathland areas such as the Quantocks and on the fringe of Exmoor, and the latter being traditionally common on the Somerset Levels and also occurring in a range of wetland habitats across the county including reedbeds, rhynes[46], and ponds. Published information indicates that 90 pairs of yellowhammer were present on the Quantocks in 2003, and 28 territorial males were present on Exmoor in 2002, but there is very limited data available for lowland farmland (Ballance, 2006). Concentrations of breeding reed bunting occur at Avalon Marshes (161 pairs in 2002), in the Catcott and Tealham/Tadham areas, where 50-70 pairs are generally present and on King’s Sedge Moor/Somerton and West Sedge Moor which both hold 100-200 pairs. There are numerous small colonies elsewhere in lowland Somerset (Ballance, 2006).

Eleven pairs of yellowhammer were recorded breeding in the SSA, with 27 territorial males across the wider area. The average density of breeding yellowhammer on lowland farmland was considered to be 11.6 pairs per km^2 in the last national breeding bird atlas (Gibbons *et al*. 1993), and (while limitations due to lack of unrestricted access during the surveys are acknowledged) the indicative density from the survey work conducted in 2007 is that 5.9 pairs per km^2 were present. This apparently low density at Hinkley is unsurprising and reflects the fact that there are a limited number of mature hedgerows with standard trees (for song posts) within the survey area, and that field boundary hedges lack associated ruderal/grassland margins throughout the SSA. Seven pairs of reed bunting were recorded within the SSA, with the 13

gardens. Caterpillars, particularly hairy species that are avoided by other birds (and are often distasteful or toxic), feature heavily in the diet (Brown & Grice, 2005).

[46] A colloquial (Somerset) word for lowland drainage channels.

pairs recorded occurring in a typical range of wetland habitats to the south and east of the built nuclear plant. Large numbers of reed bunting breed on the Somerset Levels where a total of 200-400 pairs breed on King's Sedge Moor/Somerton Moor and West Sedge Moor in most years (Ballance, 2006). Much suitable breeding habitat exists within Somerset for both species and therefore the county populations of both species are likely to be well in excess of 1,000 pairs. It is therefore concluded that the SSA is likely to of no more than local importance to both species.

Other red-listed and UK BAP Priority species recorded breeding within the survey area were skylark, dunnock, song thrush, starling and house sparrow[47]. Dunnock is included on the UK BAP Priority species list as the sub-species that breeds across much of the UK (*Prunella modularis occidentalis*) has a restricted distribution at European level (the species is also amber listed due to a moderate population decline over the past 25 years, but has shown recent signs of recovery). Dunnock is widespread and common across much of lowland England, and has relatively ubiquitous habitat preferences; hence the population in the SSA is likely to be of less than local importance. The four other red-listed species remain common or very common at county and national level, despite significant population declines. Numbers occurring in the SSA are therefore of no more than local importance.

4.1.3 Other Notable Species

Oystercatcher bred within the built power station compound. It is a scarce breeder in Somerset, but the stretch of coast between Hinkley Point and Stert is a traditional area for the species. Although there has been no county-wide survey, seven pairs were reported to the Somerset Bird Club in both 2005 and 2006, including a pair that successfully raised young at Hinkley in both years. A pair is therefore likely to be of county importance.

A total of 5-6 nightingale territories were located in scrubby woodland to the south of the built nuclear plant in 2007, all of which would be in the eastern arm of the SSA. Censuses of the county nightingale population recorded 81 territories in 26 10km squares in 1976, 169 territories across 36 10km squares in 1980 and 116 territories in 16 10km squares in 1999 (Ballance, 2006). This clearly suggests that the SSA is of county importance for the species, as 5-6 pairs is a considerable proportion of the county population. It is also apparent, that Hinkley forms one of a small network of sites that support nightingale between Watchet and the Parret Estuary, an area which is one of the county strongholds for the species. Therefore, the area of scrub adjoining the built nuclear plant at Hinkley is an important resource for the species at county level.

Lesser whitethroat is on the western edge of its range in Somerset. It favours low-lying farmland with well established dense hedgerow, and also breeds in scrubby areas. There is no contemporary estimate of the breeding lesser whitethroat population in Somerset, but in the 1980s the species was considered to breed at 76 sites within the county. Since this time it is perceived to have declined, largely due to declines in a few regularly monitored areas (Ballance, 2006). The 2007 surveys indicated that three pairs of lesser whitethroat were present in the SSA, with a further four pairs in the wider survey area. In the absence of baseline information, the population within the SSA has therefore been assumed to be of county importance.

[47] Starling and house sparrow numbers are likely to have been under recorded, as potential breeding areas such as around dwellings and farm buildings were generally excluded from the survey. Nevertheless, neither species appears particularly common in the survey area.

Rock pipit, which breeds in crevices in the coastal defences and sea wall of the built nuclear plant, is likely to be present in the survey area in numbers of county importance. Ballance (2006) suggested that approximately 50 pairs are usually present in the county, with a high concentration occurring between Hinkley Point and Watchet. Given the tendency of rock pipits to nest in the artificial habitats created by the built power station, however, it is unlikely that any negative effects on the species would result from new build.

Other breeding species are unlikely to be present in numbers of county importance. There are no recent estimates of rook abundance in Somerset, but 19,000 nests were reported from a census conducted in 1975 (Ballance, 2006), and a considerable decline since this time would have been necessary for the number of rooks breeding in the survey area to exceed 1% of the county total. The one pair of buzzard that was recorded breeding is also of local rather than regional importance as recent county bird reports state that the species is approaching carrying capacity in Somerset. In 2006 for example, 763 records involving a total of 1,932 buzzards were submitted to the Somerset Ornithological Group (Gibbs [Ed], 2007).

4.2 Intertidal and Inshore Marine Surveys

When considering bird populations outside the breeding season (i.e. the winter and passage periods), the threshold of importance (or significance) in population terms, is often taken as 1% of the (peak) number of a species known to occur within a given area. From this starting point, taking into account regularity and nature of use, it is possible to undertake a subjective analysis of the importance of an area to a bird species. The first step towards doing this for Hinkley is to define the relevant areas. In the discussion that follows, the local area has been taken as Bridgwater Bay and the immediate surrounding land, while the county is Somerset and the region is that covered in The Southwest Biodiversity Implementation Plan[48]. National refers to the United Kingdom and International to world distribution (of the bird species or race of that species concerned).

Numbers of those species (recorded in the survey area) that form part of the cited/designated interest of statutory sites within 5km of the SSA have been considered potentially significant if found to exceed 1% of the qualifying number listed in any of these site citations. To establish population estimates to provide a basis for evaluation, relevant regional and national accounts including Ballance (2006), Gibbs (Ed) 2011 and Calbrade *et al*. (2010) and the citations of designated sites have been used in conjunction with bird reports, scientific papers and information on population trends available from the BTO website (www.bto.org).

The importance of the SSA and the wider survey area to bird species has been assessed on a species specific basis using a staged process:

1. Firstly, it has been determined whether the peak number of a species present within the survey area (and each sector of it) exceeds 1% of the qualifying number of that species within the Severn Estuary SPA/Ramsar Criterion 6 or SPA Review population; if this is the case, the record, and hence the area, is of potential importance to that species at the

[48] The South-west Biodiversity Implementation Plan, which is available through the website (http://www.biodiversitysouthwest.org.uk) covers the south-west region and includes Somerset (as well as Devon, Dorset, Gloucestershire, Wiltshire, Cornwall and the Isles of Scilly). As such there is ecological data available and targets have been set for this biogeographical region. It therefore seems sensible to include this as the region for the purposes of assessment.

European level. If the species does not feature on the citations listed above or is included on the citation but does not exceed 1% of the qualifying level, then it is assessed against the criteria in 2 below;

2. Assuming the species concerned is not of significance in terms of an SPA (or SPA Review) population, the peak number of that species present within the survey area (and each sector of it) is assessed against the nationally important population SSSI citations within 5km of the SSA (often an estimate can be derived from 'potential future interest' section of the Ramsar citation if the SSSI citation is unclear). If the species features as part of the qualifying interest of a Ramsar Site (not under Criterion 6) or SSSI and numbers on site exceed 1% of the listed population estimate, the area is of potential importance at the national level. If this does not apply, the species is assessed against the criteria outlined in 3 below;

3. Assuming that the numbers of a species are not considered of importance in SPA, Ramsar or SSSI terms, the numbers present are assessed against available data on national, regional, county and local populations to determine potential importance of records and, it follows, the survey area, again using the 1% criterion.

Effects on the integrity of the statutory sites within 5km of the SSA have the potential to occur during the cited period that each of the qualifying species is present (e.g. shelduck is a qualifying species of the Severn Estuary SPA during winter, while ringed plover is a qualifying species for the SPA during passage periods). This also applies to the Bridgwater Bay SSSI, which has some common ornithological interest with the Severn Estuary SPA and Severn Estuary Ramsar site, but which support nationally important numbers of a few additional species during the passage and winter periods.

For wading birds, generally accepted definitions of the spring passage, autumn passage and winter periods have been published. In the Wetland Bird Survey annual report for 2008/09 (Calbrade *et al*., 2010), the winter period for waders is defined as November to March inclusive and that for most other water bird species (featured in the report) as being September to March inclusive. For wildfowl the seasons are less easily defined, being more species specific. As such, a variety of sources have been interrogated in order that the winter period can be reasonably defined on a species-specific basis for wildfowl in the Severn Estuary. These sources include annual Wetland Bird Survey reports published by the BTO, the Migration Atlas (Wernham *et al*., 2002), the county avifauna (Ballance, 2006) and Somerset bird reports (published by the Somerset Ornithological Society). The qualifying periods of cited interest are presented in Table 4.1.

Table 4.1 Qualifying Periods of Species[49] Included in Severn SPA (and Ramsar Site) and Bridgwater SSSI Site Descriptions[50]

Species	Severn SPA & Ramsar Site	Bridgwater Bay SSSI	Qualifying Period	Source of Information
Bewick's swan	✓	N/a	Winter (October to March)	Wernham *et al* (2002) Brown & Grice (2005)
(Russian) White-fronted goose	✓	N/a	Winter (mid September to March)	Brown & Grice (2005)
Shelduck	✓	✓	Winter (SPA & Ramsar) (September to April). Moult / early migration and dispersal period (SSSI) (June to October)	Brown & Grice (2005) Ginn & Melville (2000) Ballance (2006)
Wigeon	N/a	✓	Winter (September to March)	BTO Wetland Bird Survey Annual Reports
Gadwall	✓	N/a	Winter (September to March)	Brown & Grice (2005)

Pintail	✓	N/a	Winter (September to March)	Brown & Grice (2005)
Ringed plover	✓	N/a	Passage[51] (April to October)	BTO Wetland Bird Survey Annual Reports
Dunlin	✓	✓	Winter (November to March)	BTO Wetland Bird Survey Annual Reports
Black-tailed godwit	N/a	✓	Passage (April to October)	BTO Wetland Bird Survey Annual Reports
Whimbrel	N/a	✓	Passage (April to October)	BTO Wetland Bird Survey Annual Reports
Curlew	✓	N/a	Winter – SPA (November to March)	BTO Wetland Bird Survey Annual Reports
Redshank	✓	N/a	Winter (November to March)	BTO Wetland Bird Survey Annual Reports

[49] Qualifying species for the Severn Estuary SPA (including SPA Review), the Severn Estuary Ramsar site (under Criterion 6) and Bridgwater Bay SSSI.

[50] Winter assemblage species are not all included here. It is assumed that any additional wader species within the assemblage qualification are SPA species between November and March inclusive, while additional wildfowl that are included in the assemblage would be present between September to March inclusive.

[51] The BTO defines spring wader passage as occurring between the months of April and June inclusive, and autumn passage as occurring between July and October inclusive. The respective Severn Estuary SPA citation and Bridgwater Bay SSSI description include a total of three species that occur on passage: ringed plover (SPA), whimbrel and black-tailed godwit (SSSI). It has been assumed for the purposes of this report that these three species occur on passage throughout this seven month period (although peak passage periods are apparent in all from published sources) and that any effect on them during this time might result in an effect on site integrity.

With reference to the information presented in Table 4.1, of those species that were recorded during the survey work undertaken at Hinkley between April 2008 and March 2009 inclusive, the species that form part of the designated interest of the Severn Estuary SPA are as follows:

- Passage populations of European importance (ringed plover);
- Winter populations of European importance (shelduck, pintail, gadwall, dunlin, curlew and redshank); and
- Additional species included in the wildfowl assemblage listing (wigeon, teal, mallard, shoveler, lapwing, grey plover and whimbrel).

The Ramsar descriptions (species listed under Criterion 6) and SSSI citations include species that were recorded during the survey work undertaken at Hinkley during 2007-09. These were:

- Winter populations of international importance (shelduck, gadwall, dunlin and redshank);
- Passage populations of international importance (black-tailed godwit and whimbrel); and
- Winter populations of national importance (shelduck, wigeon and dunlin).

For the species that represent designated features (that were recorded during the surveys undertaken at Hinkley in 2007-09), a detailed assessment of the importance of the survey area (defined here as the area covered by the intertidal and inshore marine surveys and daytime field surveys) has been completed in this report. This has been undertaken through considering the number of each species that occur in the survey area (and the nature and regularity of their use of the five count sectors) against numbers listed as occurring in the statutory sites during the winter period, or where the species is designated for its passage numbers, also during the passage period. In addition, gadwall which was recorded during the surveys undertaken at Hinkley between April 2007 and March 2008 (2007/08) but not during 2008/09 has also been included. Gadwall was recorded during the field surveys but not the intertidal surveys. The importance of the survey area to other species, which are not features of these designated sites, has been more briefly assessed against published national population estimates, regional accounts and figures presented in county bird reports.

Where a species is designated for its passage numbers, the peak counts recorded in each intertidal survey count sector during the passage period (April to October inclusive) are compared to numbers recorded at the statutory sites during the passage period. Likewise, peak counts recorded at each count sector during the winter period are compared with numbers forming the designated interest of statutory sites during the winter period (November to March for waders, or September to March for most other species). For some assemblage and non-cited/designated species such as lapwing, golden plover and teal, peak counts recorded during the daytime and nocturnal field surveys (herein referred to generically as the field surveys) are also considered.

WeBS data for the local area around Hinkley (counts from WeBS Core Count and Low Tide count sectors within the Severn Estuary SPA, within (approximately) 2km of the SSA) are used to provide additional information about numbers that have occurred within or close to the survey area in recent years. These data have again been separated into the passage and winter periods where appropriate for that species (i.e. the species is cited/designated for its passage population).

Records of bird sightings from the Somerset Ornithological Society have also been used to provide contextual information about numbers occurring in the Hinkley area in recent years. For these data, National Ordnance Survey Grid References could not be provided, with records being selected by site name and thus only the approximate/likely location of the birds can be determined.

4.3 Cited/Designated Species

Table 4.2 provides a comparison of the peak counts recorded during the surveys undertaken at Hinkley during 2007-09 with the qualifying populations of statutory sites within 5km of the SSA. The following text provides an explanation of how the figures presented in this table have been derived.

Peak Sector Counts

The peak count for each of the five intertidal survey count sectors is shown for the periods (as defined in Table 4.2) for which the species appears as cited/designated interest in the statutory sites (e.g. winter and/or passage). Separate counts are shown for the periods covered by the first (April 2007 to March 2008 inclusive) and second year of the intertidal survey programm (April 2008 to March 2009 inclusive) as covered in detail in this report. Counts of commuting birds have been excluded. The peak count recorded during the daytime and nocturnal field surveys on a particular visit is also shown, for the first phase of field surveys (September 2007 to March 2008 inclusive for the daytime field surveys, and December 2007 to March 2008 inclusive for the nocturnal surveys) and second phase of field surveys (April 2008 to March 2009 inclusive for the daytime field surveys, and April-May 2008 and August 2008 to March 2009 inclusive for the nocturnal surveys). All peak counts have been derived from the largest single count of that species recorded within the count sector on a particular survey date.

Thresholds of Importance

Thresholds of national and international importance for each species are shown in the tables below. These have been derived from figures presented in Calbrade *et al*. (2010).

Qualifying Populations

The SPA/Ramsar site qualifying population is shown for those SPAs/Ramsar sites that the species appears as a cited/designated feature[52]. Unless otherwise stated, the qualifying population figure for the statutory site has been derived as follows:

- SPAs: figures derived from 5 year peak mean WeBS count for 1991/2 to 1995/6 as presented in the Natura 2000 Description for that site; and
- Ramsar sites: figures derived from the five-year peak mean WeBS count for 1998/99 to 2002/03 as presented in the Ramsar Information Sheet for that site.

[52] Species which it is suggested may merit future inclusion are also considered here for completeness.

Parrett Estuary Population

Qualifying populations for species that appear as cited/designated features of the Bridgwater Bay SSSI (but are not listed in the Ramsar description) are not available. Therefore, an indicative population figure for the SSSI has been derived from peak counts for the Parrett Estuary (including Berrow Flats and the Brue Estuary). This area covers much the same area as the SSSI. These figures have been obtained for the particular period (passage/winter) from the 2008 and 2009 Somerset Birds Reports (Gibbs [Ed] 2010, 2011).

Table 4.2 Peak Counts of Cited/designated Species during Surveys in Relation to Qualifying Populations

Species	Period	International Threshold	National Threshold	Qualifying Population		Parrett Estuary Population[53]	Peak Count in Each Intertidal Count Sector during Period[54]						Field Surveys Peak Count
				Severn Estuary SPA[55]	Severn Estuary Ramsar Site		Survey year(s)	CS1	CS2	CS3	CS4	CS5

Shelduck [SPA and Ramsar Site Qualifying Species]

Shelduck is described in Ballance (2006) as a common summer, autumn and winter visitor and passage migrant in Somerset. Bridgwater Bay SSSI, which includes the Parrett Estuary (which in turn includes Stert Flats) is the key area for passage, moulting and foraging shelduck in Somerset (Ballance, 2006). The Severn Estuary SPA has been partly designated for its winter numbers of shelduck of European importance. Nationally important congregations of moulting birds also form part of the cited interest of the Bridgwater Bay SSSI.

Shelduck numbers in Somerset peak between June and November, with an initial wave of birds passing through the county in June, July and August and birds which use Bridgwater Bay for moulting and wintering arriving during September (Ballance, 2006). Table 4.3 shows the monthly average and peak counts from the Parrett Estuary during 1987-2002 (Ballance, 2006) and the monthly peak counts recorded in each intertidal survey Count Sector, excluding counts of commuting birds.

Table 4.3 Peak Counts of Shelduck Each Month in the Parrett Estuary and Entec Survey Area during Moulting Period (June-Oct) and Winter Period (Sep-Apr)

		Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar	Apr
Peak and Mean Counts on the Parrett Estuary during 1987-2002

[56] The figures show the largest single count recorded in each count sector on a single intertidal survey date (excluding counts of birds commuting through the count sector)

		Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar	Apr
CS5	2007/08	220	106	400	700	310	250	67	52	97	76	296
	2008/09	64	234	107	280	54	46	55	109	90	55	108

The peak counts in intertidal survey Count Sectors 2, 3, 4 and 5 in 2008/09 each exceed 1% of the SPA qualifying population of 3,330 shelduck during the winter period (September to April), with that for Count Sector 5 representing 8% of the SPA population. Peak counts in Count Sectors 2, 3, 4 and 5 in 2007/08 and/or 2008/09 also exceeded 1% of the Bridgwater Bay SSSI population during the period in which groups of moulting shelduck congregate in the Bay (June to October).

However, numbers of foraging or loafing shelduck in excess of 1% of the SPA population were only recorded on a frequent basis during the winter period in Count Sector 5 (on 18 occasions in 2008/09), during both the first and second year of survey (2007/08 and 2008/09 respectively). Groups of 30-100 birds were regularly seen foraging on intertidal habitat in Count Sector 5 around low tide, with larger flocks occasionally recorded (up to 280 birds in 2008/09 and up to 700 birds in 2007/08). Groups of loafing shelduck were regularly observed loafing on the sea in all count sectors, particularly within 3 hours of high tide as birds dispersed from their feeding grounds. However, away from Count Sector 5, numbers rarely exceeded 1% of the SPA or Ramsar site populations.

As in 2007/08, numbers of foraging and loafing shelduck in Count Sectors 1-4 in 2008/09 were generally smaller. However, numbers of shelduck loafing on the sea did occasionally exceed 1% of the SPA population in Count Sectors 2 and 4 in 2008/09 and also in Count Sector 3 in 2007/08. In comparison to that in Count Sector 5, the extent of the foraging resource in Count Sectors 1-4 is limited, whereas the extent of loafing habitat is less limited.

Overall, the largest numbers of foraging shelduck that occurred in the survey area were present around low tide, feeding low on the shore on exposed mud, predominantly in Count Sector 5, on the edge of Stert Flats. These foraging birds then tended to disperse, moving offshore to form loose loafing flocks as the tide rose rather than moving into other count sectors (closer to the SSA). There is no evidence from the data collected during 2007/08 or 2008/09 that shelduck regularly roost on rocks at high water in any of the count sectors.

Results from the surveys undertaken during 2003-05 for the proposed West Hinkley Wind farm also indicate regular use by up to 400 shelduck on intertidal habitat immediately to the east of the Power Stations including in the area covered by Count Sector 5. Very few shelduck were recorded during these surveys in the area covered by Count Sectors 1-4, with no counts in excess of 1% of the SPA or SSSI populations of shelduck in these areas.

WeBS Core Count data and Somerset Ornithological Society records indicate that large concentrations of shelduck occur on Stert Flats, which includes Count Sector 5. WeBS Low Tide counts for 2008/09 recorded 185 shelduck in Count Sector 5, and 65 birds in total in Count Sectors 1-4.

The evidence from the desk study and surveys suggest that use of intertidal habitat in Count Sectors 1-4 (Sectors 1-3 include the intertidal area adjacent to the SSA) by shelduck is sporadic during the moult and winter periods, and that low numbers of birds use the intertidal zone. Count Sectors 1-4 are unlikely to support numbers of foraging or roosting shelduck that are of importance in terms of the SPA population during winter or in terms of the Bridgwater SSSI population during the moulting period. In view of this, Count Sectors 1-4 are considered to be of low importance to the SPA population of shelduck during the moulting period and winter. The large numbers of shelduck seen loafing on inshore waters within Count Sectors 1-4 during the Entec surveys were due to birds moving off the western part of the Stert Flats (including Count Sector 5) as they became inundated by the rising tide. These flocks of loafing birds were usually located more than 500m offshore (and thus outside the intertidal survey area) but would occasionally drift close inshore and into Count Sectors 1-4.

The field surveys and desk study provide no evidence to indicate that shelduck use the fields within the survey area, including those in the SSA, on a regular basis. Therefore, this area is unlikely to be of importance to the SPA population of of shelduck during the moulting period and winter.

Numbers of foraging and loafing shelduck that are important in terms of the Severn Estuary SPA population occur in Count Sector 5 on a regular basis during the winter period (September to March inclusive). The peak counts of 280 birds in 2008/09 and 700 birds in 2007/08, foraging on intertidal habitat in Count Sector 5, represents 8% and 21% of the SPA population respectively. Numbers of foraging and loafing shelduck that exceed 1% of the Bridgwater Bay SSSI population also occur in Count Sector 5 on a regular basis during the moulting period (June to October inclusive). In view of this, the intertidal habitat within Count Sector 5 is likely to provide a locally important resource to the SPA and SSSI populations of shelduck, both to foraging and loafing birds throughout much of the tidal cycle. Count Sector 5 lies on the western edge of the Stert Flats and WeBS data indicates that a considerable proportion of the SPA population of shelduck uses this area during the winter period (September to April inclusive) and the SSSI population during the moulting period (June to October inclusive).

Wigeon [SPA Assemblage and SSSI Qualifying Species]

Wigeon is described in Ballance (2006) as a common or locally abundant passage migrant and winter visitor in Somerset. The first birds arrive in the county in August, with numbers building up quickly in September and October and the bulk of birds arriving in November and December. Numbers are usually stable during January after which there is a decline, with few birds remaining in April (Ballance, 2006). The Somerset Levels SPA, which is approximately 16km to the south east of the SSA, is the most important site in the county for wigeon and the third most important area in the UK (Calbrade *et al*, 2010). The Parrett Estuary is the most important coastal site for wigeon in Somerset, with numbers tending to be at their highest during drier (and very cold) winters when birds find it hard to locate suitable flooded areas inland for roosting. Consequently, numbers vary greatly between years on the Parrett Estuary, with a peak of 5,000 birds recorded during the winter of 1996/97 compared with 1,000 birds during 2003/04. Nationally important numbers of wintering wigeon form part of the cited interest of the Bridgwater Bay SSSI of which the Parrett Estuary forms an integral part.

The peak counts for Count Sectors 4 and 5 in both 2007/08 and 2008/09 all exceed 1% of the Severn Estuary population of 8,466 birds. The peak counts for Count Sectors 4 and 5 in 2008/09 represent 1.8% and 1.3%, and those for 2007/08, 2.6% and 2.0% of the Severn Estuary population respectively.

Numbers of wigeon in excess of 1% of the Severn Estuary population (85 or more birds) were recorded feeding or loafing close to the tide line during much of the tidal cycle in Count Sectors 4 and 5 on a regular basis between November and March inclusive (on 14 and 6 occasions respectively during 2007/08 and 2008/09). In 2008/09, large counts of foraging wigeon were recorded feeding close to the waters' edge throughout much of the tidal cycle, whereas usually smaller groups of loafing birds tended to congregate close offshore two hours either side of high water. In view of this, the intertidal habitat within the survey area at Hinkley Point and immediately to the east of it is likely to provide a locally important foraging resource for the SSSI population of wigeon during winter.

The field and intertidal surveys provided no evidence for the existence of a regular roosting site for wigeon within the survey area. The survey data indicates that important numbers of wigeon forage on the intertidal habitat in Count Sectors 4 and 5 on a regular basis during the winter and that high tide roosts also occur on occasion in this area.

Somerset Ornithological Society records and surveys undertaken for the proposed West Hinkley Wind Farm indicate that numbers of wigeon in excess of 50 birds have occurred at Hinkley Point on a regular basis, including counts of 200 on 15 November 2007 and 229 on 7 February 2007. The wind farm data includes peak counts in excess of 50 wigeon on the intertidal habitat in both Count Sectors 4 and 5. WeBS Low Tide data indicates that similar-sized numbers occur on the mudflats immediately to the east of Hinkley Point (peak count of 485 wigeon in sector BV696) and the intertidal area to the west of the Power Stations and adjacent to the SSA (peak count of 185 wigeon in sector BV697).

Results from the desk study and surveys undertaken in 2007/08 and 2008/09 indicate that numbers of wigeon that are important in terms of the Severn Estuary population use the intertidal habitat in Count Sectors 4 and 5 on a regular basis for foraging (and occasionally for roosting) during the winter. The smaller expanse of suitable feeding habitat exposed at low water to the west of the Power Stations and adjacent to the SSA (Count Sectors 1, 2 and 3) is of limited (no more than local) importance to wigeon. There was also no evidence to indicate that wigeon use the fields within or close to the SSA on a regular basis or that important numbers of wigeon occur in the seasonally flooded fields to the south of the built plant within the Severn Estuary SPA.

Gadwall [SPA and Ramsar Site Qualifying Species]

Gadwall is described in Ballance (2006) as a locally fairly common, autumn and winter visitor and passage-migrant in Somerset. Currently, the Somerset Levels support the largest winter and autumn numbers of gadwall in the county, with Westhay Moor and Shapwick Heath being favoured sites. Numbers on the Parrett Estuary and surrounds are generally small and use of the area is sporadic. The Severn Estuary SPA and Ramsar site has been designated partly on the basis of its wintering gadwall population of European importance.

As there was only one gadwall recorded during the entire ornithological survey programme, and no previous desk study information indicating more historical use of the survey area, it is reasonable to conclude that the area is of low (or even negligible) importance to the SPA population.

Teal [SPA Assemblage and Possible Future Ramsar Site Qualifying Species, SSSI Qualifying Species]

Teal is described in Ballance (2006) as a scarce breeder, but a common or locally abundant winter visitor and passage migrant in Somerset. The influx of wintering birds begins in mid July, and continues through to November and December when the bulk of birds arrive. Numbers peak in January and then decline from February onwards, with few present by the end of the March (Ballance, 2006).

The Somerset Levels are currently the most important site for wintering teal in the UK (Calbrade *et al*, 2010). Good numbers also occur on the Parrett Estuary, with 1,600 birds recorded there in December 2005 (Gibbs [Ed], 2006). Internationally important numbers of wintering teal (4,456 birds) appear as a possible feature for future inclusion as part of the cited interest of the Severn Estuary Ramsar site and this species also appears in the wildfowl assemblage listing for the Severn Estuary SPA. Internationally important numbers of wintering teal that occur in the Severn Estuary also appear as cited interest for the Bridgwater Bay SSSI, which supports a substantial proportion (1,600 birds) of the entire Severn Estuary population.

Teal were not recorded using the intertidal survey area (Count Sectors 1-5) during the intertidal surveys undertaken in 2008/09. However, the peak count of 25 birds loafing on the sea in Count Sector 4 in January 2008 represents 1.6% of the Bridgwater Bay SSSI population. Numbers exceeding 1% of the SSSI population were recorded on one occasion in 2007/08. Very few foraging birds were noted.

Results from the daytime field surveys in 2007/08 and 2008/09 indicate that the network of ditches and ponds to the south of the Power Stations occasionally support numbers of teal that exceed 1% of the (potential) Ramsar site and SSSI populations. The pond to the east of the sewage works, (south of the built plant) was identified as being of particular local importance to teal. Numbers of teal that exceed 1% of the (potential) Ramsar site population were recorded foraging or loafing on this pond during winter 2008/09 on seven occasions. The field and intertidal surveys provided no evidence for the existence of a regular roosting site for teal within the survey area.

WeBS data and results from survey work undertaken for the West Hinkley Wind Farm indicate that teal use the mudflats immediately to the east of Hinkley Point in numbers that occasionally exceed 1% of the SSSI population. WeBS Core Count data indicate that much larger numbers of teal occur on the more extensive areas of intertidal habitat on the Stert Flats to the east of the survey area. During the West Hinkley Wind Farm surveys teal were also recorded flying between mudflats to the east of Hinkley Point and the pools to the south of the Power Stations.

Overall, evidence from the surveys and desk study indicate that within the survey area, the network of ditches and pools to the south of the built plant provide a locally important foraging resource to the Severn Estuary population and Bridgwater Bay SSSI population of teal during the winter period (September to March inclusive). All other areas within the survey area at Hinkley have generally low or negligible levels of use by teal and are therefore unlikely to be of importance to the SSSI population.

Mallard [SPA Assemblage Species]

Mallard is described in Ballance (2006) as a common resident breeder, winter visitor and passage migrant in Somerset. Mallards will use a wide range of habitats for foraging, including estuaries, rivers, streams and small ponds. It is therefore likely that WeBS data, which are primarily derived from counts of birds on large water bodies, underestimates the true numbers of mallard present in the Somerset. Counts of mallard from 20-30 selected sites in the county regularly total more than 1,000 birds (Gibbs [Ed] 2011). In view of the likely widespread occurrence of suitable habitat and inferred distribution of this species in Somerset, the winter population of mallard in the county is likely to be well in excess of 10,000 birds. Large numbers winter on inland reservoirs and on the Somerset Levels, with relatively small numbers present on the Parrett Estuary (Gibbs [Ed], 2011). Mallard is not a qualifying species of either the Severn Estuary SPA or the Bridgwater Bay SSSI. However, in the winter, the Severn Estuary regularly supports numbers of waterfowl that are of European importance, including mallard, which is listed in the winter assemblage qualification for the SPA.

Results from the intertidal and daytime field surveys undertaken at Hinkley during 2007/08 and 2008/09 indicate that there is a relatively low level of use by mallard of the intertidal habitat adjacent to the SSA, and the network of ditches and pools to the south of the built plant. WeBS data, Somerset Ornithological Society records and surveys undertaken for the proposed West Hinkley Wind Farm also provide no evidence to indicate that important numbers of mallard occur locally. Overall, within the survey area, the intertidal habitat, pools and network of ditches to the south of the Power Stations provide a locally important foraging resource, with much more extensive areas of suitable habitat found to the east in Bridgwater Bay and on the Somerset Levels. The survey area is therefore likely to be of low importance to the Severn Estuary population of mallard during the winter period (September to March inclusive).

Pintail [SPA Review and Possible Future Ramsar Site Qualifying Species]

Pintail is described in Ballance (2006) as a locally fairly common winter visitor and passage migrant in Somerset. Pintail arrive in the county from August to December, with many of the earlier birds only using the area on passage. Numbers peak in January and February, with flocks of birds moving between the Somerset Levels, inland reservoirs and the Parrett Estuary. During the development of the West Sedge Moor Nature Reserve on the Somerset Levels in the 1990s, numbers of pintail increased at this site whilst declining on the Parrett Estuary, although this situation has since been reversed, and there was a count of 143 on the Parrett Estuary in January 2006 (Ballance, 2006., Gibbs [Ed], 2007). Wintering numbers of pintail of European importance are a recommended addition to the qualifying interest of the Severn Estuary SPA (599 birds) in the SPA review (Stroud *et al*., 2001). Internationally important numbers of wintering pintail appear as a possible future feature for addition to the qualifying interest of the Severn Estuary Ramsar site.

The peak counts in intertidal survey Count Sectors 3, 4 and 5 in 2007/08 and 2008/09 all exceeded 1% of the SPA Review population of pintail. Important numbers of pintail in terms of the SPA Review population were recorded foraging on the tide line or loafing on the sea in Count Sectors 4 and 5 on two and nine occasions respectively in 2008/09 (six and twelve occasions respectively in 2007/08). Foraging activity was recorded primarily during low tide (three hours either side of low water) and loafing birds congregated offshore two hours either side of high tide. Use of Count Sectors 1-3 by foraging and loafing pintail was very sporadic in 2007/08 and 2008/09.

There is no evidence from the intertidal survey data collected in 2007/08 and 2008/09 of a regular high tide roost of pintail in any of the count sectors. The largest numbers of pintail occur in the survey area around low tide, feeding in intertidal habitat predominantly in Count Sectors 4 and 5, on the edge of Stert Flats. These foraging birds tend to disperse, moving offshore to form loose loafing flocks as the tide rises rather than moving into other count sectors closer to the SSA.

WeBS data, Somerset Ornithological Society records and results from the winter bird surveys undertaken for the proposed West Hinkley Wind Farm during March 2006 indicate that pintail occur in intertidal habitat to the east of Hinkley Point in the area approximately covered by Count Sector 5 (at least 1km east of the SSA), with numbers generally ranging between 30-100 birds. These data also suggest that the numbers using the Hinkley Point area represent a large proportion of the total using the Stert Flats and Bridgwater Bay. Results from the desk study and field surveys provide no evidence of pintail using the fields, ditches and other water bodies within the Entec fields survey area.

There is no evidence to suggest that intertidal habitat to the west of the built nuclear plant, and that adjacent to the proposed new build area is used by important numbers of pintail on a regular basis and therefore this area is likely to be of no more than local importance to the species during the winter period (September to March inclusive). The intertidal habitat around Hinkley Point (including that in Count Sectors 4 and 5) held numbers of pintail that are important in terms of the Severn Estuary SPA Review population on 11 and 18 occasions during the winters of 2007/08 and 2008/09 respectively. Within the survey area, the intertidal habitat to the north and north-east of the operational plant are likely to provide a locally important foraging resource for the SPA pintail population.

Shoveler [SPA Assemblage Species]

Shoveler is described in Ballance (2006) as a locally fairly common winter visitor and passage migrant in Somerset. The first winter visitors and passage migrants arrive in Somerset in August, September and October, with the bulk of birds appearing in November and December. Numbers peak in January and February, but stay at relatively high levels until the end of March when a second increase occurs as a result of an influx of passage birds en route to breeding areas. Shoveler appears in the waterfowl assemblage listed for the Severn Estuary SPA and nationally important wintering numbers (297 birds) appear as noteworthy fauna in the description for the Severn Estuary Ramsar site. Numbers on the Somerset Levels and Severn Estuary appear to have increased since designation and both currently hold internationally important numbers of shoveler; with the 5 year mean peak WeBS counts for 2004/05 to 2008/09 inclusive being 1,286 and 561 birds respectively (Calbrade *et al*, 2010). Numbers found on the Parrett Estuary (peak count of 45 birds in 2009, Gibbs [Ed] 2011) are small in comparison to those found on the Severn Estuary as a whole.

Results from the intertidal surveys undertaken at Hinkley in 2007/08 and 2008/09 indicate that small groups of 1-4 shoveler use Count Sectors 3 and 5 on an infrequent basis. Shovelers were not recorded during the field surveys in 2007/08 or 2008/09. Surveys undertaken for the proposed West Hinkley Wind Farm recorded peak counts of 11 and 22 birds in March 2006 although no shoveler were noted in the winter bird study area during the first and second phases of surveys in 2003-05.

Counts of shoveler that exceeded 1% of the Ramsar site population (297 birds) were recorded on one occasion during the Entec intertidal surveys undertaken in 2007/08 and 2008/09 and twice during the West Hinkley Wind Farm surveys. In view of the evidence from the surveys and desk study, the intertidal survey area at Hinkley is likely to be of low or negligible importance to the Ramsar site population of shoveler on a regular basis during the winter period (September to March inclusive).

Ringed Plover [SPA Review and Possible Future Ramsar Site Qualifying Species]

Ringed plover is described in Ballance (2006) as a scarce breeder and fairly common winter visitor and passage migrant in Somerset. The main sites for ringed plover in Somerset are on the Parrett Estuary and Dunster Beach where numbers of birds peak in August and September (Ballance, 2006). Passage numbers of ringed plover of European importance are a recommended addition to the qualifying interest of the Severn Estuary SPA (655 birds) in the SPA review (Stroud *et al*., 2001). Internationally important numbers of passage ringed plover appear as a possible future inclusion into the designation of the Severn Estuary Ramsar site.

During the intertidal surveys undertaken at Hinkley in 2007/08 and 2008/09, ringed plover were recorded throughout much of the passage period (April to October inclusive), and on a regular basis in Count Sector 1 (on 12 occasions between April and October 2008 inclusive). Numbers were generally small (usually involving 1-3 foraging or roosting birds), but occasional larger flocks were observed, including a notable count of 33 roosting birds on 19 September 2008.

During 2007/08, ringed plover were recorded foraging or loafing on the beach in Count Sector 1 on nine occasions during the passage period. Elsewhere within the survey area, the intertidal habitat was used more infrequently by 1-2 ringed plovers.

Counts of foraging, loafing or roosting ringed plover in excess of 1% of the Severn Estuary SPA Review population of 655 birds were recorded (during the passage period in 2008) on two occasions in Count Sector 1, and also once in Count Sector 2. The peak count of 33 roosting birds in Count Sector 1 in September 2008 represents slightly in excess of 5% of the SPA Review population. A count of ringed plover in excess of 1% of the SPA Review population was recorded on one occasion in 2007, also in Count Sector 1. Results from the daytime and nocturnal field surveys in 2007/08 and 2008/09 indicate that use of the fields and surrounding ditches and wet areas within the survey area was very limited during the passage period.

Results from the West Hinkley Wind Farm surveys included a peak count during the passage period of 12 birds in October 2004 (details of the location of the birds is unavailable) representing more than 1% of the SPA Review population. However, this count was exceptional, with no birds recorded on most visits and occurrence within the survey area was sporadic.

Somerset Ornithological Society records show that small numbers of ringed plover occur around Hinkley Point (which is likely to include all or the majority of Count Sectors 4 and 5), and that larger numbers use the Stert Flats to the east of the survey area. WeBS Core Count data also indicate that a large proportion of the Severn Estuary population occurs on the Stert Flats during the passage period, with the largest numbers seen in August (a peak count of 780 birds recorded there in August 2006), and that numbers occur at much lower levels during the winter period.

The survey data provides no evidence for the presence of a regular roosting site for ringed plover within the survey area during the passage period. It is therefore likely that small numbers of ringed plover feed on the shoreline within the survey area during low water, after which they disperse to roost sites.

During the winter period (November to March inclusive), 1-2 ringed plover were recorded regularly in the intertidal survey area. Ringed plover were noted foraging, loafing or roosting in Count Sector 1 on six and 13 occasions respectively during the 2007/08 and 2008/09 intertidal surveys, with a peak count of 12 roosting birds there on 12 February 2009. Counts in excess of two birds were observed on two and five occasions in Count Sector 1 during 2007/08 and 2008/09 respectively. Ringed plover were recorded more infrequently in the other count sectors during winter (3, 3 and 1 occasions in Count Sectors 2, 4 and 5 respectively). Results from the West Hinkley Wind Farm surveys included peak counts during the winter period of 22 birds in December 2003 and 23 birds in December 2004, although on most visits, no ringed plover were counted (details of the location of the birds is unavailable). Numbers of ringed plover in Somerset are generally much smaller in the winter than during the passage period (Ballance, 2006), and include county totals of 145 birds in January 2007, 124 birds in November 2005 and 88 birds in January 2009 (Gibbs [Ed], 2006, 2007, 2011). Even allowing for birds residing in coastal areas away from the main sites, that are not included in these county totals, the county population of ringed plover during the winter is unlikely to be much in excess of 200 birds. In view of this, the numbers of ringed plover using Count Sector 1 during the winter are occasionally of county importance. Count Sectors 2-5 are used infrequently and are therefore likely to provide a no more than locally important resource to ringed plover during the winter.

To summarise, the intertidal habitat within the survey area is likely to provide a limited resource for foraging and roosting ringed plover during the passage period, with much more extensive areas of suitable habitat being found to the east, in Bridgwater Bay. The evidence from the desk study and surveys indicates that numbers of ringed plover that are important in terms of the Severn Estuary SPA population occur occasionally in Count Sectors 1 and 2 and that there is generally low level use of the area during the passage period. In Count Sectors 3-5, SPA important numbers of ringed plover were not recorded. In view of this, the intertidal habitat within the survey area, including that adjacent to the SSA is likely to be of low importance to the SPA population of ringed plover during the passage period. During the winter, the intertidal habitat in Count Sector 1 occasionally supports numbers of foraging, roosting and loafing ringed plover that are of county importance.

Grey Plover [SPA Assemblage Species]

Grey plover is described in Ballance (2006) as a fairly common, but very local winter visitor and passage migrant in Somerset. In Somerset, most grey plover occur on the Parrett Estuary, where the mean counts for 1983-2003 for the peak months of December, January and February are 213, 214 and 204 birds respectively (Ballance, 2006). The Severn Estuary supports nationally important numbers of grey plover during winter, with Bridgwater Bay SSSI holding a considerable proportion of the total. In addition, grey plover appears in the winter assemblage qualification for the Severn Estuary SPA.

No grey plover were recorded during the intertidal surveys undertaken in 2008/09. In 2007/08 this species was recorded on two occasions, involving a maximum of three birds. However, 1-2 grey plover were heard or observed feeding in the intertidal survey area on five dates during nocturnal field surveys undertaken in January, February and March 2009.

WeBS data, Somerset Ornithological Society records and results from surveys undertaken for the proposed West Hinkley Wind Farm during 2003-06 also provide no evidence to suggest that grey plover occur on a regular basis within the survey area. WeBS data indicates that much larger numbers (150-500 birds) occur on the Stert Flats to the east of Hinkley Point. Good numbers (304 birds) were recorded duing WeBS Low Tide counts in 2008/09 on mudflats approximately 1km to the east of the survey area.

To summarise, the intertidal area within the survey area (including that around Hinkley Point and to the west, adjacent to the SSA) is used by grey plover on a very infrequent basis. In view of this low level use of the site, the survey area is likely to be of less than local importance to grey plover during the winter period (November to March inclusive).

Lapwing [SPA Assemblage Species]

Lapwing is described in Ballance (2006) as a fairly common but local breeder, and abundant winter visitor and passage migrant in Somerset. The first wintering lapwings appear in Somerset in June or July, but most arrive in October, November and December (Ballance, 2006). The largest numbers occur in the county when birds are forced south and west by prolonged cold weather. The Somerset Levels are the main site in the county for lapwing, with 69,758 birds recorded there in January 2006, compared to 7,300 birds on the Parrett Estuary in the same month (Gibbs [Ed], 2007). The Somerset Levels is now the most important site for wintering lapwing in the UK and an internationally important site for the species (Calbrade *et al.*, 2010). Lapwing is not a qualifying species of either the Severn Estuary SPA, Severn Estuary Ramsar site or the Bridgwater Bay SSSI. However, this species does appear in the winter assemblage qualification for the SPA.

Foraging, loafing and roosting lapwing were not recorded on a regular basis in the intertidal survey area during 2008/09 or 2007/08 (on 5, 1 and 2 occasions respectively between April 2008 and March 2009 inclusive). In 2007/08, almost all activity was in Count Sectors 4 and 5, and in 2008/09 no lapwing were recorded outside these count sectors.

Results from the field surveys undertaken at Hinkley indicated that the favoured areas for lapwing were arable fields in the west and south of the planning application boundary, and the pasture around Wick Moor to the south of the built plant (outside the planning application boundary). Lapwings were observed foraging in fields with the survey area on most field surveys undertaken during December 2008 to February 2009 inclusive. The largest counts were on 10-11 January and 6-7 February 2009, including a total of 117 birds within the planning application boundary on 7 February. The largest counts outside the planning application boundary were primarily in fields at Wick Moor, and included a total of 147 birds on 16 November 2007 and 130 birds on 10 January 2009. Table 4.4 shows the total number of lapwing counted during the field surveys on each date, within and outside the planning application boundary.

Table 4.4 Total Number of Lapwing Recorded on Each Date during Entec Field Surveys at Hinkley[57]

Date	With SSA	Outside SSA	Total
16/11/2007		147	147
17/12/2007	60	2	62
21/12/2007	17	7	24
22/12/2007	1	52	53
14/02/2008	29		29
18/02/2008	44		44
07/08/2008	3		3
14/08/2008	2		2
22/10/2008	4		4
11/12/2008		10	10
17/12/2008	18	8	26
10/01/2009	5	130	135
11/01/2009		46	46
15/01/2009	13		13
29/01/2009		30	30
06/02/2009	88		88
07/02/2009	117	44	161
24/03/2009	3		3

[57] Counts of commuting birds have been excluded.

Small numbers of lapwings were recorded in fields within the SSA and those to the south of the built plant during the nocturnal surveys undertaken in 2008/09. However, the surveys undertaken in 2007/08 and 2008/09 provide no evidence to suggest that large numbers of lapwing were roosting in these areas.

Accurate information on the likely size of the lapwing population in the local area and within the county of Somerset as a whole during the winter is not available. WeBS counts are predominantly undertaken on estuaries and at the larger wetland sites and not on farmland where important numbers of lapwing occur during winter. In most winters the county population is likely to be in excess of 50,000 to 100,000 birds, as lapwing will occur on farmland out with the Somerset Levels. Results from the surveys undertaken at Hinkley during 2007/08 and 2008/09 indicate that numbers of lapwing of county importance (i.e. more than 1% of the likely population in Somerset) occur irregularly during the winter. Evidence from the desk study and surveys indicates that the fields and intertidal habitat within the survey area are likely to provide a limited foraging and roosting resource to lapwing. In view of this, the survey area (including the fields within the planning application boundary) is likely to be of no more than local importance to lapwing during the winter period (November to March inclusive).

Dunlin [SPA, Ramsar Site and SSSI Qualifying Species]

Dunlin is described in Ballance (2006) as an abundant winter visitor and common passage migrant in Somerset. The main area for passage and winter dunlin is Bridgwater Bay (Ballance, 2006) of which the Parrett Estuary often holds more than 10,000 birds during November to February. The Severn Estuary SPA is designated partly on the basis of dunlin numbers of European importance during the winter (44,624 birds). Internationally important numbers of dunlin during winter (25,082 birds) are a cited/designated feature of the Severn Estuary Ramsar site. Nationally important winter numbers (11,650 birds) appear in the citation for the Bridgwater Bay SSSI.

Dunlin were not recorded using the intertidal habitat at Hinkley for foraging, loafing or roosting during the intertidal surveys undertaken during the winters of 2007/08 or 2008/09 (November to March inclusive). Low level use of the intertidal area was recorded irregularly during the spring and autumn passage period (April to October inclusive). Results from winter bird surveys undertaken for the proposed West Hinkley Wind Farm also indicate a low level of use of intertidal habitat adjacent to the Power Stations and SSA. WeBS data suggest that much larger numbers (sometimes in excess of 10,000 birds) occur on the Stert Flats, 2-5km east of the survey area.

The evidence indicates that the intertidal habitat around Hinkley Point and that adjacent to the SSA is used by small numbers of dunlin on a relatively infrequent basis. The survey area is likely to be of low or negligible importance to the Severn Estuary SPA/Ramsar site populations and Bridgwater Bay SSSI population of dunlin during the winter period (November to March inclusive).

Black-Tailed Godwit [SSSI Qualifying Species]

Black-tailed godwit is described in Ballance (2006) as a locally common winter visitor and passage migrant in Somerset. Internationally important numbers of passage black-tailed godwit form part of the cited interest of the Bridgwater Bay SSSI. Peak numbers of black-tailed godwit occur on the Parrett Estuary during summer and early autumn (Ballance, 2006), with 172 and 110 birds counted respectively August and September 2009 (Gibbs [Ed] 2011).

During the 2008/09 intertidal surveys, black-tailed godwits were recorded on two occasions, both during the passage period, including a large flock of 100 birds foraging on intertidal habitat in Count Sector 5 in August 2008, which is likely to represent at least 30% of the Bridgwater Bay population. Black-tailed godwits were recorded on one occasion during intertidal surveys undertaken in 2007/08 (involving six birds in December and therefore outside the passage period for which this species appears as a cited feature).

Single black-tailed godwits were recorded in the survey area on two occasions during surveys undertaken for the proposed West Hinkley Wind Farm during 2003-06 (the activity of these birds is not known). WeBS data indicates that large numbers of black-tailed godwits occur to the east on the Stert Flats, where e.g. 148 birds were noted in September 2008.

The evidence indicates that the intertidal habitat around Hinkley Point and that adjacent to the SSA is used by black-tailed godwit on a very infrequent basis during the passage period. Numbers that are important in terms of the Bridgwater Bay population occur very occasionally, with more extensive areas of suitable foraging habitat lying to the east of Hinkley. The surveys provide no evidence of roosting black-tailed godwits at Hinkley.

In view of this low level of use, it is likely that the survey area is of low importance to the SSSI population of black-tailed godwit during the passage period (April to October inclusive).

Whimbrel [SPA Assemblage and SSSI Qualifying Species]

Whimbrel is described in Ballance (2006) as a passage migrant that is more common in the spring than autumn in Somerset, and the species appears in the waterfowl assemblage qualification for the Severn Estuary SPA. The Bridgwater Bay SSSI was originally notified partly on the basis of its important numbers of passage whimbrel (160 birds, Gibbs [ed] 2011), and nationally important passage numbers appear as noteworthy fauna in the description for the Severn Estuary Ramsar site (333 birds).

Whimbrel were recorded on a regular basis in the spring passage period (April and May) during the intertidal surveys undertaken at Hinkley in 2007 and 2008 (on a total of 29 occasions). Smaller numbers were seen irregularly during the return autumn passage period of July to October (on a total of nine occasions). Foraging or loafing birds were observed in all count sectors, but were irregular (seen on one occasion) in Count Sector 1 and most commonly recorded in Count Sectors 4 and 5. Results from the field surveys provide no evidence to suggest that whimbrel were using fields within the survey area for foraging or roosting on a regular basis. Table 4.5 shows the peak count of whimbrel recorded during the Hinkley intertidal surveys in each count sector during each month of the passage period in 2007 and 2008.

Table 4.5 Peak Count of Whimbrel Recorded in Each Intertidal Count Sector during Entec Intertidal Surveys in 2007 and 2008[58]

Count Sector	Year	Apr	May	Jun	Jul	Aug	Sep	Oct
1	2007							
1	2008		1					
2	2007	3	2					
2	2008	3	5			2		
3	2007		1					
3	2008	1	1					
4	2007	3	4			1		
4	2008	2	4	2	1	1		
5	2007	8	15		2	1		
5	2008	7	3					

Whimbrel was not recorded on any of the bird surveys undertaken for the proposed West Hinkley Wind Farm during 2003-06 (some of these surveys were conducted during late August and September in 2004 (i.e. part of the usual autumn passage period for whimbrel) although none were carried out during the spring passage period. WeBS data and records from the Somerset Ornithological Society indicate that larger numbers of whimbrel occur around Hinkley Point and to the east of the survey area on Stert Flats during spring passage. The peak (WeBS Core Count) numbers of whimbrel recorded on the Stert Flats during 2004/05 to 2008/09 were 14, 7, 3, 28 and 6 birds respectively. A total of 101 whimbrel were counted on the Severn Estuary in May 2006 (Musgrove *et al*., 2007) and there were peak counts of 160 and 81 whimbrel on the Parrett Estuary (including the Berrow Flats) in April and May 2009 (Gibbs [Ed], 2011). Numbers appear to peak on the Parrett Estuary in April and May, with much smaller numbers passing through the area during autumn, mainly in August and September when counts rarely exceed five birds.

The evidence suggests that the survey area is used by numbers of whimbrel that are important in terms of the Bridgewater Bay SSSI population during spring passage (April and May). The intertidal habitat in Count Sectors 4 and 5 was particularly favoured. Whimbrel were recorded using Count Sector 4 on five and seven occasions respectively during the 2007 and 2008 passage periods, including counts of four birds on one date in each year. In Count Sector 5, whimbrel were recorded on 12 and three occasions respectively in 2007 and 2008, including counts in excess of 1% of the SSSI site population on seven and three occasions respectively in 2007 and 2008.

Count Sector 2 is likely to provide a locally important foraging resource to whimbrel during the passage period (whimbrel were recorded using the intertidal habitat on two and five occasions respectively during the 2007 and 2008 passage periods). Whimbrel were recorded less

[58] Counts of commuting birds have been excluded.

frequently in Count Sectors 1 and 3 being observed using the intertidal habitat on a total of one and four occasions respectively during the 2007 and 2008 passage periods. It is therefore concluded that these sectors are likely to be of less than local importance to the species. Smaller numbers of whimbrel occur more irregularly during the autumn passage period (July to October inclusive), primarily commuting through the area, but occasionally stopping off to feed in intertidal habitat.

Curlew [SPA Review Qualifying Species, Potential Future Ramsar Qualifying Species]

Curlew is described in Ballance (2006) as an uncommon breeder, common winter visitor and passage migrant in Somerset. Wintering numbers of curlew of European importance are a recommended addition to the qualifying interest of the Severn Estuary SPA (3,903 birds) in the SPA Review (Stroud *et al.*, 2001). Nationally important numbers of passage curlew (2,021 birds) appear as noteworthy fauna in the description for the Severn Estuary Ramsar site. Curlew arrive in the county between June and October (on autumn passage), with smaller but still substantial numbers remaining through the winter until late March (Ballance, 2006). The Parrett Estuary is currently the most important site in Somerset for passage and wintering curlew.

Table 4.6 shows the (mean) peak counts on the Parrett Estuary during 1981-2003 (Ballance, 2006); maximum counts of curlew on the Parrett Estuary in each month between April 2008 and March 2009 inclusive (Gibbs [Ed] 2010, 2011) and the peak counts (excluding commuting birds) recorded in the five intertidal count sectors between April 2007 and March 2008 inclusive (2007/08) and April 2008 and March 2009 inclusive (2008/09). The peak count each month during the field surveys are also shown (derived from summing the counts in each field on any one date).

Table 4.6 Peak Counts of Curlew by Month in the Parrett Estuary and the Entec Survey Area

		Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar
Mean Peak Counts on the Parrett Estuary During 1981-2003

		Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar
Fields	2008/09	0	0	0	0	0	2	3	12	19	20	14	8

NB: Field surveys were not undertaken in April to August 2007 inclusive and only single visits were made in September and October 2007. Therefore, the absence of curlew in fields during these months does not necessarily indicate that little egret do not use this area at this time of year (although this can be inferred from the data for 2008/09).

Foraging, roosting and loafing curlew were consistently recorded during the 2007/08 and 2008/09 survey periods. Numbers using the intertidal habitat were higher between July and the following March inclusive (covering the entire autumn passage and winter periods) and at their lowest during April, May and June (the spring passage period).

During the 2008/09 intertidal surveys, one count (of 63 birds foraging in Count Sector 5) exceeded 1% of the SPA Review population during the winter period, and none during the 2007/08 surveys. During the passage period, no counts in 2008/09 exceeded 1% of the (potential) Ramsar site population, although in 2007/08, numbers of importance to the (potential) Ramsar site, were recorded on seven occasions (of which five were of roosting birds). These counts were all during August, September and October, with two counts each in Count Sectors 2, 3 and 4 and one in Count Sector 5. Groups of 20-29 roosting birds were noted on seven occasions within two hours of high tide in Count Sector 4, both during the passage and winter periods in 2007/08. In 2008/09, numbers were smaller, although 10-20 curlew were recorded roosting in Count Sector 4 on five occasions.

Curlew (usually 1-10 birds) were seen foraging in fields around Hinkley during the field surveys undertaken in 2007/08 and 2008/09, predominantly between November and February, with none seen during April to August inclusive[59]. The most favoured area for feeding curlew were the fields within or adjacent to the western end of the SSA. None of the total (summed) counts in all fields within the survey area, on any one date, exceeded 1% of either the SPA or Ramsar populations during the winter and passage periods respectively.

Curlews were recorded regularly in intertidal habitat adjacent to the SSA and built nuclear plant during surveys undertaken for the proposed West Hinkley Wind Farm in 2003-06. Numbers that exceeded 1% of the SPA Review population were recorded during six of seven survey visits conducted in March 2006 although no details were provided as to where these birds were recorded within the survey area. Numbers that exceeded 1% of the Ramsar site population were recorded on one occasion during the wind farm surveys during the passage period, in October 2004. Curlew were occasionally recorded in fields close to the shoreline during 2003-06, although the report stated that there was no evidence of regular use of fields to the west of the nuclear facility (Dulas, 2006). WeBS Core Count data indicate that much larger numbers of curlew occur to the east of the survey area on the Stert Flats (of which Count Sector 5 forms a small part), with counts in excess of 1,000 birds recorded during the passage and winter periods. WeBS Low Tide counts for 2008/09 recorded peak counts of 98 birds in Count Sector 5 and a total of 28 birds in Count Sectors 1-4 during the winter. Somerset Ornithological Society records for the passage and winter periods respectively, from Hinkley Point (which is likely to include part or all of Count Sectors 4 and 5), include peak counts of 80 birds in September 2001 and 30 birds in March 1997. These records include several counts of curlew at Hinkley Point that are in excess of 1% of the Ramsar population during the passage period but none of importance to the SPA Review population during winter.

Evidence from the surveys and desk study indicate that intertidal habitat within the survey area is used by numbers of foraging curlew that are of importance in terms of the Severn Estuary SPA Review population on a sporadic basis during the winter period (numbers in excess of 1% of the SPA population were not recorded in 2007/08 and on one occasion during 2008/09). In

[59] Field surveys were not undertaken in April to August 2007 inclusive and only single visits were made in September and October 2007. Therefore, the absence of curlew in fields during these months does not necessarily indicate that they did not use this area during these months (although the likelihood can be inferred from the data for 2008/9).

view of this, the intertidal habitat in Count Sectors 1-5 is likely to be of low importance to the SPA population of curlew during the winter period (November to March inclusive).

Numbers of foraging or roosting curlew that are of importance in terms of the Ramsar site population are likely to occur on intertidal habitat within Count Sectors 2-5 inclusive on a regular basis during the passage period in some years (i.e. none in 2008 and on seven occasions during 2007 of which five records were of roosting birds). In view of this, it is concluded that the intertidal habitat within Count Sectors 2-5 provide an important foraging resource and roosting area for the Severn Estuary Ramsar population of curlew during the passage period (April to October inclusive) and particularly during autumn passage (August, September and October).

Redshank [SPA and Ramsar Site Qualifying Species]

Redshank is described in Ballance (2006) as an uncommon breeder, fairly common winter visitor and passage migrant in Somerset. The two main sites in the county for redshank are the Parrett and Axe Estuaries (Ballance, 2006). Average monthly counts on the Parrett Estuary during 2000 to 2003 for August to March inclusive range between 340 birds (February) and 897 birds (September) (Ballance, 2006). Redshank is a winter qualifying feature of the Severn Estuary SPA, which is listed as supporting 2,330 birds and of the Severn Estuary Ramsar site (2616 birds).

Redshank (mostly 1-2 birds) were recorded using intertidal habitat within the survey area at Hinkley on 12 and seven occasions respectively during 2007/08 and 2008/09, predominantly during the autumn and winter (September to March inclusive). The only count of note was of 22 birds foraging in Count Sector 5 in December 2008 and no counts exceeded 1% of the SPA population. Results from the field surveys provide no evidence of redshank using the network of ditches and pasture to the south of the built plant within the survey area on a regular basis (recorded on one and two occasions respectively during 2007/08 and 2008/09).

Very few redshank were recorded within the survey area during work undertaken for the proposed West Hinkley Wind Farm between 2003 and 2006. Records from the Somerset Ornithological Society also indicate that intertidal habitat around Hinkley Point is not used by large numbers of redshank. WeBS data, however, indicates that much larger numbers of redshank occur on the Stert Flats to the east of the survey area with 400-1,000 frequently recorded.

The evidence suggests that use of the intertidal habitat and fields within the survey area by redshank is very low and of negligible importance to the SPA/Ramsar site populations during the winter.

Other Cited/designated Species

Of the remaining species that appear as cited/designated features (including waterfowl assemblage species) of statutory sites within 5km of the SSA during passage and winter, Bewick’s swan, white-fronted goose tufted duck and pochard were not recorded during the surveys undertaken at Hinkley during 2007/08 or 2008/09. Results from the desk study provided no evidence to suggest that any of these species use the survey area on a regular basis during the passage and winter periods. In view of this low level of use, the survey area is likely to be of less than local importance to these species during the autumn and winter.

4.4 Non-Cited/Designated Species

4.4.1 Wildfowl and Other Water Birds

A further ten species of waterfowl and other water birds that do not appear as cited/designated features of statutory sites within 5km of the SSA were recorded during the surveys undertaken at Hinkley during 2008/09. Of these, mute swan, brent goose, scaup, ruddy duck, shag, grey heron and water rail were either recorded irregularly or in relatively small numbers in 2008/09. Ruddy duck, brent goose, water rail and scaup were not recorded in 2007/08, and mute swan, shag and grey heron irregularly or in very small numbers. Results from the desk study (including WeBS data and Somerset Ornithological Society records) also provide no evidence to suggest that the survey area was being used by important numbers of these species. In view of this and the low level of use of the site by these species in 2007/08 and 2008/09, the intertidal habitat and fields within the survey area are likely to be of no more than local importance to these species.

Common scoter was regularly recorded in flocks of up to 25 birds on the sea during 2007/08, but few were seen in 2008/09 (1-8 birds on six occasions). At no time during either the 2007/08 or 2008/09 surveys did the numbers of common scoter represent an important proportion (i.e. more than 1%) of the internationally important Carmarthen Bay population (mean peak count of 17,656 birds from 2004/05 to 2008/09, Calbrade *et al*., 2010), which is located approximately 100km to the northwest of Hinkley. In view of this, it is likely that the inshore waters at Hinkley provide no more than a locally important feeding resource to common scoter, in some winters. Of the remaining species, the importance of the survey area to cormorant and little egret, which was recorded regularly during the surveys, is discussed in more detail below:

Cormorant

Cormorant is described in Ballance (2006) as a fairly common winter visitor, passage-migrant and non-breeding summer visitor in Somerset. The peak counts of cormorant in Somerset in 2005 and 2006 were 235 (January) and 287 (October) respectively. Counts on the Parrett Estuary in the same years peaked at 24 (January) and 35 (September) birds respectively (Gibbs [Ed] 2006, 2007). Results from the intertidal surveys undertaken at Hinkley during 2007/08 and 2008/09 indicate that cormorant (usually 1-5 birds) use the intertidal habitat within the survey area for loafing and to a less extent foraging. Although it is recognised that many cormorants using inland open freshwater bodies and inland waterways are unlikely to be accounted for in these figures, it is likely that the numbers of cormorant using the survey area are of county importance.

Little Egret

Numbers of little egret occurring in the UK have increased substantially since 1990, when the species was on the British Birds Rarities Committee list[60], although in recent years the expansion in terms of both range and numbers may have started to slow (Collier *et al*, 2005, Calbrade *et al*., 2010). BTO monthly indices illustrate a strong post-breeding peak in September, and a low point from April to July when birds probably either return to French breeding colonies or (increasingly) become more secretive around British ones. Whilst there is

[60] The authenticity of all records required consideration by a panel of experts following the submission of a written description.

still no official 1% national threshold value for this species, Calbrade *et al*. (2010) indicates that sites with mean counts of at least 50 individuals might be nationally important.

Nationally important numbers of little egret feature as noteworth fauna in the Severn Estuary Ramsar site description (17 birds), although the peak counts for the Severn Estuary during 2007/08 and 2008/09 (based on the WeBS recorded year of July to the following June) were 105 and 103 birds respectively (Calbrade *et al*., 2010). This indicates that the national population increase in little egret has been mirrored in the Severn Estuary and Somerset populations. Roost counts of 40-60 birds have been recorded from at least two Somerset locations, and the species is now widespread throughout lowland areas of the county. It follows that the WeBS may not, therefore, provide accurate data on overall numbers or the rate of population increase in Somerset, and the Severn Ramsar Information Sheet is clearly out of date (the figure is derived from the 5 year mean peak count for 1998/99 to 2002/03 inclusive). A total of 123 birds were counted from nine sites in Somerset in July 2007 (Gibbs [Ed], 2008) indicating that the present county population is likely to be well in excess of 100 birds during the late Summer and early Autumn.

More locally, peak counts from the Stert Flats include at least 48 birds in October 2006 (Somerset Ornithological Society records) and 42 birds in September 2005 (WeBS Core Count data). WeBS data for 2002-06 indicate that little egret numbers are at their highest on the Stert Flats in September and October. **Table 4.7** shows the maximum counts of little egret on the Parrett Estuary in each month between April 2008 and March 2009 inclusive (Gibbs [Ed], 2010, 2011) and the peak counts (excluding commuting birds) recorded in the five intertidal count sectors between April 2007 and March 2008 inclusive. The peak count each month during the field surveys are also shown (derived from summing the counts in each field on any one date).

Table 4.7 Peak Counts of Little Egret by Month in the Parrett Estuary and the Entec Survey Area

		Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar

CS4	2008/09	1	1	2	1	2	4	2	1	1	1	1	0
CS5	2007/08	3	5	2	5	5	4	3	2	1	1	2	1
CS5	2008/09	2	1	1	2	2	2	5	2	0	2	1	1
Fields	2007/08	No count	No count	No count	No count	No count	0	0	2	2	3	1	1
Fields	2008/09	1	3	1	0	1	2	8	0	5	1	2	1

NB: field surveys were not undertaken in April to August 2007 inclusive and only single visits were made in September and October 2007. Therefore, the absence of little egret in fields during these months does not necessarily indicate that little egret do not use this area at this time of year.

Against this background of sustained increase, it is difficult to assess the value of the survey area to little egret. Foraging and loafing birds were seen on a regular basis at low water throughout much of 2007/08 and 2008/09 in all count sectors, with 1-2 birds generally present in each count sector in 2008/09, with slightly larger numbers in Count Sectors 3, 4 and 5 in 2007/08 (1-3 birds in Count Sector 3, 1-4 birds in Count Sector 4 and up to five birds in Count Sector 5).

One to three birds were regularly counted in ditches surrounding fields to the south of the built plant within the survey area with occasionally larger numbers present (two counts of five birds and one count of eight birds in 2008/09). There is some evidence in 2008/09 to suggest that little egret were moving between fields and ditches south of the built plant and intertidal habitat to the north, with birds observed flying north from the fields around Wick Moor. Birds were also seen flying east and west along the shoreline through the intertidal survey area.

Currently the best available data suggests that numbers in each of the count sectors are still likely to exceed 1% of the current population for the Severn Estuary Ramsar site on a regular basis. In 2008/09, counts of three or more birds were recorded on eight occasions during the passage period (August to November inclusive), with too few records to indicate any preference for a particular count sector. In 2007/08, three or more birds were recorded on 24 occasions during the passage period of which all but six records related to foraging birds in Count Sectors 4 and 5.

However, in view of the relatively low level of use in Count Sectors 1-3 (generally 1-2 birds), this suggests that if the county and Severn Estuary populations continues to rise and a constant level of use within the survey area is assumed, these sectors will become of no more than local importance to little egret in the short to medium term.

To summarise, numbers of foraging and loafing little egret that exceed 1% of the published Severn Estuary Ramsar site population occur in Count Sectors 4 and 5, and are likely to occur in fields immediately south of the Power Stations on a regular basis during the passage period (August to November inclusive). These areas are therefore likely to provide a locally important foraging resource to the Severn Ramsar population.

4.4.2 Waders

In addition to those species of wader that have already received detailed assessment in this report, a further seven species were recorded during the intertidal and field surveys undertaken at Hinkley between April 2008 and March 2009 inclusive. Of these, common sandpiper and knot were recorded irregularly during 2007/08 and 2008/09 and in view of this transient use of the survey area, the area is considered to represent a less than locally important foraging resource to them. Of the remaining species, oystercatcher, golden plover, purple sandpiper, snipe and turnstone were recorded on a more regular basis. The value of the survey area to these species is discussed below. Table 4.8 shows the peak counts for these species for the Parrett Estuary and sites counted in Somerset during 2008 and 2009 (Gibbs [Ed], 2010, 2011), and the peak counts recorded during the intertidal and field surveys during 2007/08 and 2008/09 (excluding counts of commuting birds).

Table 4.8 Peak Counts of Waders in Somerset, the Parrett Estuary and Survey Area

Species	Somerset[61]		Parrett Estuary[62]		Intertidal Count Sectors, Peak Counts during 2008/09 and 2007/08 (in parenthesis)				
	2008	2009	2008	2009	CS1	CS2	CS3	CS4	CS5
Oystercatcher	511	514	328	289	20 (89)	100 (57)	79 (95)	60 (55)	13 (26)
Golden plover	22,233	20,370	3,480	2,300	37 (27) - daytime (daytime) field surveys				
Purple sandpiper	19	13	16	13	0 (2)	7 (0)	9 (15)	0 (1)	0 (0)
Turnstone	349	499	243	358	21 (20)	13 (9)	5 (8)	3 (8)	13 (1)
Snipe	2,145	1,582	n/a	n/a	20 (19) - daytime (nocturnal) field surveys				

NB: peak counts for oystercatcher, purple sandpiper and turnstone are taken from the intertidal surveys and those for golden plover and snipe are the peak count in any one field during the field surveys.

Oystercatcher

Oystercatcher is described in Ballance (2006) as a fairly common winter visitor, passage-migrant and non-breeding summer visitor in Somerset. It is the only wader species that can regularly be found along the entire Somerset coast (Ballance, 2006) and therefore WeBS and Somerset Ornithological Society data, which are concentrated at key estuarine sites are likely to under-represent the true size of the wintering population in Somerset. However, Ballance (2006) stated that oystercatchers mainly occur at three key sites in the county: the Axe and Parrett Estuaries and Dunster Beach.

Foraging and roosting oystercatchers were found in all count sectors throughout much of the year during the intertidal surveys undertaken at Hinkley in 2007/08 and 2008/09, with numbers at their lowest in May and June and relatively constant through the remainder of the year. Up to 20 oystercatchers were recorded on a regular basis foraging on intertidal habitat in all count sectors and groups of 10-50 roosting birds were seen in all but Count Sector 5 and most regularly in Count Sectors 3 and 4 in 2008/09. Similar levels of use of the site were recorded in 2007/08.

WeBS data for oystercatcher and results from surveys undertaken for the proposed West Hinkley Wind Farm during 2003-06 are consistent with those obtained from the intertidal surveys during 2007/08 and 2008/09. On the basis of the county totals presented in Table 4.8, the numbers of foraging and roosting oystercatcher using the survey area are likely to be of county importance on a regular basis during the autumn and winter. The intertidal habitat within the survey area is likely to provide an important foraging resource and roosting sites for oystercatcher within the county. The results of the surveys and desk study also indicate that the

[61] Figures for Somerset are the peak monthly count from the main sites counted (i.e. the sum of counts from the main sites counted that month).

[62] Includes Stert Point/Flats, Stert to Knighton beach.

fields within the survey area are used very irregularly, and are likely to be of less than local importance to oystercatcher throughout the year.

Golden Plover

Golden plover is described in Ballance (2006) as a common winter visitor and passage migrant in Somerset. The main sites for this species during winter and autumn are Exmoor and the Somerset Levels (Ballance, 2006). The numbers of wintering golden plover in Somerset vary considerably between years. Large influxes of golden plover to Somerset occur when there is hard weather to the east and/or north and, conversely, birds leave the county during freezing conditions. The first passage golden plover arrive in August, with larger numbers of wintering birds appearing from late September through to November and peak numbers generally occurring during January and February. The Somerset Levels and Severn Estuary currently hold internationally and nationally important numbers of golden plover during the winter respectively (5 year peak mean counts during 2004/05 - 2008/09 of 11,219 and 4,745 birds respectively, Calbrade *et al*., 2010). However, large numbers of golden plover winter on arable farmland on sites that are not included in WeBS counts and therefore WeBS data are likely to under-represent the true county total. Even allowing for considerable annual variation in numbers, the county population is likely to be well in excess of 10,000 birds in most winters.

Golden plover were recorded during the field surveys undertaken at Hinkley during 2007/08 and 2008/09, primarily in the period December to March inclusive. The most favoured areas in 2008/09 were outside the SSA, in fields immediately to the west and south of it. Numbers varied considerably between visit dates, with the largest total number of golden plover in all fields on any single date 127 birds (all outside the SSA) on 7 February 2009. Within the SSA, golden plover were recorded on one date during 2008/09 (a total of seven birds on 10 January). In 2007/08, the vast majority of records of golden plover were from fields within, or adjacent to the planning application, with the largest total count in all fields within the SSA being eight birds on 18 February 2008.

During surveys undertaken for the proposed West Hinkley Wind Farm, counts of 189 and 332 golden plover were recorded in the winter bird study area in February 2005 and March 2006 respectively, the latter count coinciding with cold weather in eastern Britain. These numbers (and the peak count of 127 birds from the Entec surveys) are likely to be of county importance although overall, golden plover were recorded on few occasions during the entire West Hinkley Wind Farm survey period (2003-06) and therefore it is likely that these numbers are unusual if not exceptional.

The evidence from the desk study and surveys suggest that numbers of golden plover using the survey area during the winter are unlikely to be of county importance on a regular basis (and reach this threshold on isolated occasions). In general, the arable fields within the survey area are limited in size (providing a limited foraging and roost site resource) and would therefore not be expected to support large flocks of plovers on a regular basis during winter. Much more extensive areas of more suitable foraging habitat exist outside the survey area within the county, particularly on the Somerset Levels. In view of this, the survey area is likely to be of no more than local importance to golden plover.

Purple Sandpiper

Purple Sandpiper is described in Ballance (2006) as a scarce and very local winter visitor and rare passage migrant in Somerset. There is no regular autumn passage of purple sandpiper in Somerset and wintering birds usually do not arrive until November (Ballance, 2006). Numbers of purple sandpiper peak in December and January, after which there is a decline, with a few lingering into April or even May. The main wintering site for the species in Somerset is now along the rocky beach from Hinkley Point west to Watchet, with up to eight birds present in most years (Ballance, 2006). In 2008 and 2009, Hinkley Point held nearly all of the county population with peak counts during the winter of 16 and 13 birds respectively (Gibbs [Ed], 2010, 2011)..

During the intertidal surveys undertaken at Hinkley, counts of 2-5 (and occasionally up to nine) purple sandpiper were regularly recorded loafing on the intake tower in Count Sector 3 during April and May 2008 and between November 2008 and March 2009. Similar numbers were recorded between November 2007 and March 2008.

These birds are likely to represent a substantial proportion of the county total. Results from the desk study indicate that the numbers recorded during winters 2007/08 and 2008/09 might be exceptional. This species was recorded on one occasion during the West Hinkley Wind Farm surveys undertaken during 2003-06 involving one record of 25 birds in 2003. Somerset Ornithological Society records indicate that although purple sandpipers were recorded regularly along the Hinkley coast during 1999-2006, no more than two birds were recorded at any one time. More recent counts, in 2008 and 2009, indicate that larger numbers do occur in the Hinkley to Watchet area (Gibbs [Ed], 2010, 2011). Purple sandpipers were not recorded during the WeBS counts at Hinkley.

However, purple sandpipers are relatively unobtrusive in rocky habitat and these habitats support few species and are therefore likely to be under-watched, leading to this species being under-recorded. This leads to the view that the numbers of purple sandpiper found in Somerset are likely to be larger than baseline data suggests. It follows that the numbers recorded at Hinkley during the intensive programme of Entec surveys undertaken in 2007/08 and 2008/09 may be typical of the area in most years. Notwithstanding this, the county population is unlikely to be in excess of 500 birds and the conclusion is that the survey area is of county importance to purple sandpiper during the winter.

Snipe

Snipe is described in Ballance (2006) as a common winter visitor and passage migrant and an uncommon resident or migrant breeder in Somerset. WeBS and Somerset Ornithological Society data, which are concentrated at key wetland sites, are likely to under-represent the true size of the wintering population of snipe in Somerset. Large numbers of snipe winter on the Somerset Levels and this species is likely to be widespread in small numbers across much of the county, wherever flooded fields, wet meadows and ditches occur. The peak count for Somerset in 2009 was 2,145 birds in January (Gibbs [Ed], 2011), and this total is likely to represent a relatively small proportion of the actual county total. The peak count of 20 birds recorded during the field surveys in 2008/09 (and 19 birds in 2007/08) are likely to represent a small proportion (less than 1%) of the county total during winter. The most favoured areas were the damp fields and ditches to the south of the built plant, around Wick Moor. This area is likely to provide a limited foraging recourse and roosting site for snipe, with much more extensive areas of suitable habitat to be found in the Somerset Levels. In view of this, the survey area is likely to be of no more than local importance to snipe during the autumn and winter.

Turnstone

Turnstone is described in Ballance (2006) as a locally common winter visitor and passage-migrant in Somerset. Turnstones occur along much of the Somerset coastline and therefore

WeBS and Somerset Ornithological Society data, which are concentrated at key estuarine sites are likely to under-represent the true size of the wintering population in the county. The main wintering and passage areas for turnstone in Somerset are on the Parrett Estuary and Dunster Beach (Ballance, 2006). Turnstones are recorded regularly in Somerset throughout the year, although peak numbers generally occur in August, September and October.

Foraging, loafing and roosting turnstone were recorded on a regular basis during the winter, spring and autumn passage periods during the intertidal surveys undertaken at Hinkley in 2007/08 and 2008/09. Even allowing for birds not included in the county totals presented in Table 4.8, (i.e. those that occur along rocky stretches of the coastline away from the main sites), the intertidal habitat within the survey area is likely to support numbers of turnstone that regularly exceed 1% of the county total during the winter and passage periods. Within the survey area, the rocky intertidal habitat to the west of Hinkley Point covered by Count Sectors 1-4 is likely to provide an important foraging and roost site resource to the county population.

4.4.3 Gulls, Terns and Skuas

Ten species of gulls and terns were recorded during the surveys undertaken at Hinkley between April 2008 and March 2009. None of these species appear as cited/designated interest for statutory sites within 5km of the SSA during the winter and passage periods. Nationally important breeding numbers of herring gull (1,540 pairs) appear as noteworthy fauna in the description for the Severn Estuary Ramsar site, and internationally important breeding numbers of lesser black-backed gull appear as a possible future inclusion for the designation of the Severn Estuary Ramsar site. Of the species recorded during the surveys, Mediterranean gull, kittiwake and Sandwich tern were seen irregularly in very small numbers (two, one and one occasions respectively). In view of their transient use of the site, the survey area is likely to be of less than local importance to them.

Arctic tern and common tern were recorded in potentially notable numbers (in terms of county or regional populations) during the intertidal surveys undertaken at Hinkley in 2007/08. However, in 2008/09, Arctic tern was seen on one occasion (involving 5 birds off Count Sector 4 in August 2008), and 2-10 common terns were observed foraging in Count Sectors 2, 3 and 4 on three dates (two in May and one in September 2008). Both species are considered by Ballance (2006) to be fairly common passage migrants in Somerset. In most years, low numbers pass along the Somerset coast, with larger numbers blown inshore during strong westerly winds. The numbers recorded in 2007 at Hinkley were considered to be of county importance, with the outfall off Count Sector 3 providing a locally important foraging resource to these species. However, in light of the low numbers and irregular occurrence of both species at Hinkley in 2008, it is clear that use of the area is sporadic and prone to substantial fluctuation between years. As birds recorded cannot be ecologically linked to local populations, it is not possible to ascribe a geographical context in terms of valuation of the resource. All that can be concluded is that the resource appears of no more than local importance.

Of the remaining species, five species of gull (black-headed, herring, lesser black-backed, great black-backed and common) were recorded in potentially notable numbers on a regular basis during the intertidal surveys. The value of the survey area to these species is discussed below.

Common gull and great black-headed gull were recorded in relatively small numbers at Hinkley in 2007/08 and 2008/09.

- Most records of common gull were of 1-2 foraging or loafing birds, recorded on 13 of 50 dates between April 2008 and March 2009 inclusive. Common gulls were not recorded in the survey area between April and August;

- Great black-backed gulls were seen consistently throughout much of the year during the survey periods (2007/08 and 2008/09), with most records involving 1-2 loafing or foraging birds on intertidal habitat or the sea.

Numbers and population trends in gulls outside the breeding season are very difficult to reliably estimate for Somerset. There are a number of reasons for this; noting gull numbers during WeBS counts is optional; juvenile and immature gulls provide difficulties in identification for many observers, hence records are not submitted to bird clubs or conservation bodies and; areas which attract large numbers of gulls, such as landfill sites, pasture and newly ploughed fields are not necessarily attractive to recreational birdwatchers. Table 4.9 gives an idea of monthly fluctuations in gull numbers at regularly counted Somerset sites, as well as peak counts for each count sector during the survey period.

Table 4.9 Thresholds of Importance and Counts of Gulls in Somerset

* Great black-backed gulls and common gulls are likely to be very widely distributed in small numbers along much of the Somerset coastline during autumn and winter and therefore under-represented in the figures given for the county in Table 4.9. The counts provided in Table 4.9 are therefore likely to represent a small proportion of the actual county total.

As is apparent from the data, none of the peak sector counts of any of the five regularly recorded gull species approaches the threshold of national importance. It is also apparent that the sum of peak monthly maxima at regularly counted sites (from Gibbs [Ed], 2007, 2006) can fluctuate considerably between years for individual species, and many areas that are attractive to gulls will be irregularly or never counted. These counts are therefore possibly most useful in illustrating relative gull abundance within the county over the survey period rather than as indicative county population estimates.

The intertidal habitat within the survey area, and in particular, the outfall and built nuclear plant, are likely to provide a locally important resource for foraging and loafing common and great black-backed gulls throughout much of the year. Much larger expanses of suitable foraging habitat are located inland, and in the Parrett Estuary to the east of the survey area, and therefore, it is unlikely that numbers of great black-backed gull or common gull using the survey area are of county importance.

Black-headed Gull

Black-headed gull is described by Ballance (2006) as an abundant winter visitor and passage migrant in Somerset. Black-headed gulls do not breed regularly in Somerset but are present in the county throughout the year. Black-headed gulls arrive in large numbers in the county from July onwards, with the bulk of the population departing in late February and March. Data on the size of the population in the county is patchy and likely to be very incomplete but counts have included 25,000 birds on Cheddar Reservoir in January 1984 and 40,000 birds on the Parrett Estuary in October 1989. On the basis of the readily available information it is not possible to accurately estimate the number of black-headed gulls that occur in the county. However, in view of the large counts mentioned above and the data presented in Table 4.9, the county population is likely to be well in excess of 50,000 birds during the autumn and winter in most years. In common with other gull species in the county, the pattern of use of roosting sites has varied with the changing location of landfill sites and decrease in winter flooding inland (Ballance, 2006).

Overall, results from the surveys undertaken at Hinkley during 2007/08 and 2008/09 indicate that the intertidal area is used by black-headed gulls on a regular basis, with birds foraging and loafing on intertidal habitat and inshore waters in all count sectors. Numbers were similar during the two survey periods (2007/08 and 2008/09) and although recorded throughout the year, lower counts were generally made between April and June. Counts in excess of 100 birds were rarely recorded. In relation to the county total, the peak count of 1,000 birds recorded in Count Sector 5 during the 2007/08 intertidal surveys was exceptional and may be of county importance. Somerset Ornithological Society records, WeBS data and results from the surveys undertaken during 2003-06 for the proposed West Hinkley Wind Farm also support this conclusion.

Groups of foraging and loafing black-headed gulls were also frequently recorded in fields to the west and south of the built plant during the field surveys undertaken at Hinkley in 2007/08 and 2008/09. Counts of 50-100 birds were recorded in fields on four occasions in 2008/09, all in autumn and winter. Results from the intertidal, daytime or nocturnal field surveys, provide no evidence to indicate that large numbers of black-headed gulls (in excess of 50 birds) were roosting on a regular basis on the intertidal habitat, built plant or surrounding fields. In view of the evidence provided by the surveys and desk study, the survey area is (generally) likely to be of no more than local importance to black-headed gull.

Lesser Black-Backed Gull

Internationally important numbers of breeding lesser black-backed gulls (4,617 pairs, Seabird 2000 Census) are listed for possible future consideration for addition to the cited/designated interest of the Severn Estuary Ramsar site. No counts in excess of 1% of this figure were recorded during the intertidal surveys undertaken at Hinkley during the breeding season (April to July inclusive) in 2007 and 2008. Counts of ten or more birds were recorded on seven occasions between April 2008 and March 2009 inclusive. Few foraging or roosting lesser black-backed gulls were seen, and most records related to individuals or small groups of birds loafing on the sea and intertidal habitat. In view of the low level of use by lesser black-backed gull, the intertidal habitat at Hinkley is unlikely to be of importance to the potential Ramsar site population and is of no more than local importance to this species throughout the year.

Herring Gull

Herring gull is described in Ballance (2006) as a fairly common resident breeder, winter visitor and passage migrant in Somerset. Nationally important breeding numbers (1,540 pairs, Seabird 2000 Census) of herring gull appear as cited/designated interest of the Severn Estuary Ramsar site. Large numbers of herring gulls were recorded on a frequent basis in the intertidal survey area during the 2008 breeding season period (April to July inclusive), with counts of 30 or more loafing and foraging birds noted on 11 occasions (43 in 2007).

Results from the intertidal surveys undertaken at Hinkley between April and July 2008 inclusive, indicate that Count Sector 3 was again the most favoured area for herring gulls, with counts of 30 or more (usually loafing) birds recorded on eight occasions (27 occasions in 2007). Large counts of herring gull were more infrequent in the other count sectors. The built plant at Hinkley and the intertidal habitat and inshore waters in Count Sector 3 are therefore considered to provide an important resource to nesting, foraging and loafing herring gulls during the breeding season, many of which are likely to originate from the Ramsar site population.

Data on the size of the population outside the breeding season in the county is patchy and likely to be very incomplete but recent counts include 6,000 birds on Wimbleball Lake in January 2006 and 3,000 birds on the Parrett Estuary in March 2005. In view of this, the county population is likely to peak at well in excess of 10,000 birds during most winters.

Overall, results from the surveys undertaken at Hinkley during 2007/08 and 2008/09 indicate that the intertidal area is used by relatively large numbers of herring gulls on a regular basis, with birds foraging and loafing on intertidal habitat and inshore waters in all count sectors. Counts of 100 or more birds were recorded on 39 and 20 occasions in 2007/08 and 2008/09 respectively, with a large proportion being of loafing birds in Count Sector 3. The largest numbers were consistently recorded in and around the built nuclear plant in Count Sector 3, with counts above 100 birds recorded infrequently outside this area. The maximum count of 350 birds recorded in Count Sector 3 in March 2008 may exceed 1% of the county total. Somerset Ornithological Society records and results from the surveys undertaken during 2003-06 for the proposed West Hinkley Wind Farm also indicate that numbers of herring gull of county importance may occasionally occur in the survey area, although are unlikely to do so on a regular basis.

Groups of foraging and loafing herring gulls were also recorded frequently in fields to the west and south of the built plant during the daytime field surveys undertaken at Hinkley in 2007/08 and 2008/09. Numbers of 100 or more birds were recorded on five occasions in fields during 2008/09, all in autumn and winter. Results from the intertidal, daytime or nocturnal field surveys, provided no evidence to indicate that large numbers of herring gull (in excess of 100 birds) were roosting on a regular basis on the intertidal habitat, built plant or surrounding fields.

To summarise, evidence from the surveys and desk study indicate that the built nuclear plant and adjacent rock platforms may occasionally hold county important numbers of herring gull outside the breeding season. Outside of this area, the intertidal habitat and adjacent fields within the survey area are likely to be of no more than local importance to this species.

4.4.4 Birds of Prey

A total of seven species of bird of prey were recorded in the survey area between April 2008 and March 2009. Results from the surveys and desk study indicate regular use of the survey area by hunting and commuting kestrel, sparrowhawk, buzzard and peregrine and occasional or low level use by merlin, red kite, marsh harrier and barn owl.

Kestrel, buzzard and sparrowhawk are common species in Somerset (Ballance, 2006) and although use of the site by these species was regular, given the habitat present and the relatively small size of the survey area in relation to the county as a whole, it is likely to provide a foraging resource that is of no more than local value to them. For red kite, merlin, marsh harrier and barn owl, the level of use of the survey area during the two survey periods (2007/08 and 2008/09) was low, with red kite was not recorded in 2008/09, and marsh harrier not recorded in 2007/08. In view of this, the survey area is likely to be of less than local importance as a foraging resource for these species.

Peregrine

One or two peregrines were recorded hunting or loafing in the survey area on 16 occasions (throughout much of the year) during the field surveys undertaken at Hinkley between April 2008 and March 2009. In 2007/08, 1-3 peregrines were recorded regularly during the field and intertidal surveys. Results from surveys undertaken for the proposed West Hinkley Wind Farm during 2003-06 also indicate that peregrines occur on a regular basis within the survey area during autumn and winter. This species is described in Ballance (2006) as an uncommon resident breeder and fairly common winter visitor and passage migrant. A total of 26 pairs were present in Somerset during the breeding season in 2002 (Ballance, 2006) although it is not known whether the birds recorded at Hinkley are derived from the local breeding population or from migrant birds. Peregrines are not thought to have bred on the built plant at Hinkley in recent years (Dick Best, British Energy Site Warden, pers comm.). Peregrines were reported from 93 sites throughout the year in Somerset in 2009 (Gibbs [Ed], 2011) indicating that this species is now widespread in the county.

The evidence from the surveys and desk study indicate that at least 1-3 peregrines use the fields and intertidal habitat around Hinkley for hunting and commuting on a regular basis. A much larger expanse of mudflats and other intertidal habitat is located immediately to the east of the survey area, which is likely to provide this species with much more important hunting areas than those found around Hinkley. In view of this, the survey area is likely to provide a no more than locally important foraging resource to peregrine.

4.4.5 Other Species

Results from the surveys undertaken at Hinkley between April 2008 and March 2009, indicate that a wide range of other species occur in or use the survey area, including (occasionally) large flocks of wintering passerines such as skylark[66] (600-700 birds in February 2009), linnet (140 birds in November 2008) and fieldfare (300 birds in November 2008). There is little data to provide any indication of the likely size of the wintering populations of widespread farmland passerines in Somerset but given the amount of suitable farmland habitat available in the county they are likely to be substantial. The peak number of skylarks recorded in fields at Hinkley may be of county importance. However, numbers of none of the farmland passerine species recorded using the survey area, are likely to be of county importance on a regular basis.

The nocturnal field surveys undertaken by Entec in 2008 located at least two territories each of nightingale and Cetti's warbler, both located immediately to the south of the built plant. Recent breeding bird surveys of the Hinkley Nature Reserve by ADAS in 2008 identified two pairs of nightingale in this area, as well as two pairs of lesser whitethroat (within the planning application boundary). The results for these species, from the 2008 Entec nocturnal field surveys and the 2008 ADAS surveys, do not differ markedly from those found during the 2007 Entec surveys undertaken in the same area. An assessment of the importance of the Hinkley populations of these species is provided in the first Interim Hinkley Bird Report. Overall, the SSA is likely to support county important populations of Cetti's warbler, nightingale and lesser whitethroat.

[66] Peak numbers in parenthesis.

5. Conclusions

The SSA, surrounding farmland and adjacent intertidal habitat and inshore waters to the east and west of the proposed Hinkley C were subject to intensive ornithological survey between April 2007 and March 2009 inclusive. The novel data collected, and the extensive contextual information resulting from various sources, including previous power station applications, the BTO's Wetland Bird Surveys and the West Hinkley Wind Farm application, mean that the ornithological interest of the area is very well understood.

The principal interest of the intertidal area is the large number of shelduck that regularly occur on intertidal mud at the western end of Stert Flats. This area is relatively remote from the terrestrial footprint of the plant, and could potentially be subject to greater effects during operation than construction (thermal regime change and chemical discharge have the potential to influence the biomass of prey and the structure of the community in this area). Up to 21% of the Severn SPA shelduck population have been recorded using this discrete area, and flocks of birds exceeding 1% of the interest of the SPA and SSSI are recorded regularly during the moult (mid summer to autumn) and winter periods. Elsewhere within the study area numbers are typically small and use irregular, although occasional flocks of loafing birds drift west on the tide (following feeding on Stert Flats) and can enter the inshore waters adjacent to the SSA. During the moult period some of these flocks will contain numerous flightless birds, potentially sensitive to disturbance. Use of fields within and adjacent to the SSA by shelduck was very limited, and there was no evidence to suggest local roosting or from the nocturnal surveys.

Other SPA species that showed relatively regular use of the area were pintail and curlew. Pintail was present in winter only, with birds almost exclusively recorded from the intertidal rock platforms to the north and the intertidal mud to the north-east of the operational plant. Flocks exceeded 1% of the SPA Review population on 29 occasions over the two years of survey, indicating that use is relatively sporadic, but regular. Curlew numbers were lower in SPA (Review) terms, with only one flock (also on Stert Flats) exceeding 1% of the cited/designated population during the survey period, but very consistent use of the area by foraging birds. More historical data from the West Hinkley Wind Farm application suggests that larger numbers have occurred on the western end of the Flats in previous years.

Ringed plover was irregularly recorded during the surveys, mostly during the autumn passage period. The western end of the intertidal survey area was favoured. Here, the combination of rock platforms and mobile sand provide foraging and roosting opportunities. Although numbers present occasionally exceeded 1%[67] of the SPA (Review) population during the survey work, it is unlikely that the area is of particular importance to the population, based on the considerable amount of similar habitat to the west (over 9km of similar coast) and the irregularity of use.

Other SPA and Ramsar species were recorded on such an infrequent basis during survey work as to suggest the area was of limited importance to them. SSSI species that were recorded using the area, particularly the flats and adjacent rock platforms to the north and north-east of the operational plant on a regular basis were whimbrel (during spring passage) and wigeon (winter).

[67] The largest flock recorded in the area accounted for approximately 5% of the SPA Review population.

The walkover surveys (nocturnal, 'field by field' and breeding bird work) established that the farmland habitat that dominates the SSA is relatively representative of the wider area. The arm of flat, open land that extends inland across Wick Moor, and which is subject to SPA, Ramsar and SSSI designation does not currently hold wildfowl during winter (with very few birds noted over the two years of work), probably due to the fact that it is rather dry. Lapwing and golden plover use farmland throughout the area, occasionally in numbers that are likely to be of importance at the county level, while large flocks of wintering passerines such as skylark and linnet also occur on an irregular basis.

The breeding bird community across much of the SSA and the surrounding area is reflective of intensively farmed habitats, with relatively low numbers of farmland birds present among a community dominated by common species with ubiquitous habitat preferences. The exception to this, is the species rich area in the mosaic of habitats to the south of the built plant. This area supports the only Schedule 1 species recorded breeding within the survey area, Cetti's warbler, as well as populations of nightingale and lesser whitethroat, which have a restricted regional range. The high incidence of peregrine sightings throughout the year suggests breeding may soon occur on the operational plant, while barn owl does not breed in the survey area (and has not been recorded doing so for well over 20 years) probably predominantly due to an absence of nesting opportunities.

[68] Species that appear as featured interest for at least one of the statutory sites within 5km of the SSA (including possible future designation under Ramsar Criterion 6) and species which appear as noteworthy fauna in the information sheet for the Severn Estuary Ramsar site.

[69] Locations identified as being within or less than 1km from the intertidal survey area and/or the survey area used for the daytime field surveys.

[70] Peak count of individuals recorded for that location that year. Blank fields do not necessarily indicate that no birds were present, but could relate to birds not being counted at that location that year.

[71] Species that do not appear as a featured interest for at least one of the statutory sites within 5km of the PWA or as noteworthy fauna for the Severn Estuary Ramsar site.

[72] Locations identified as being within or less than 1km from the intertidal survey area and/or the survey area used for the daytime field surveys.

[73] Peak count of individuals recorded for that location that year during the months of January, February, March, August, September, October, November and December (i.e. those covered by the surveys undertaken at Hinkley in 2007/08). Blank fields do not necessarily indicate that no birds were present, but could relate to birds not being counted at that location that year.

Appendix C
Intertidal Survey, Peak Monthly Counts[74]

13 Pages

[74] The figures show the peak count of birds on any single survey date within the month. The peak counts have been derived from the sum of all counts of birds within the count sector on any single survey date (excluding counts of birds commuting through the area).

Table C.1 Cited/Designated Species

1. Introduction

1.1 Purpose of this Report

EDF Development Company Ltd (EDF) is proposing to submit a planning application for a new nuclear power station at Hinkley Point, Somerset. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) has been commissioned to co-ordinate the baseline ornithological and terrestrial ecological survey work to support this application. Ornithological desk study and survey work relating to the development proposal commenced in April 2007. Results from the programme of ornithological work undertaken within the immediate vicinity of the proposed site for new nuclear build during 2007-09 are summarized in the Hinkley Baseline Ornithological Report (Entec doc. ref. 19801cb376).

The effects of warm water emitted from the outfall facility of the new nuclear Power Station has been identified as a potential impact on the populations of waterfowl (including waders, ducks and geese) using the mudflats to the east of the existing built power plant. This intertidal area is located within the Severn Estuary Special Protection Area (SPA) and Ramsar site, and the Bridgwater Bay SSSI. In order to provide additional information on the location and numbers of waterfowl using mudflats that could be potentially affected by the warm water outfall, additional intertidal bird surveys were undertaken between April 2010 and January 2011 inclusive. This report summarises the findings from these surveys.

1.2 Scheme Description

An area of land directly west of the Hinkley 'A' and 'B' Power Stations has been identified as having the potential to accommodate nuclear new build. The new power station and the majority of associated permanent terrestrial infrastructure will be situated in fields adjacent to the coast[1], with additional temporary infrastructure located to the south of this (e.g. construction compounds and areas for soil storage). This area is referred to as The Strategic Site Area (SSA), the boundary of which is shown on **Figure 1.1**.

The new build will also require additional infrastructure remote from the immediate terrestrial site footprint. This will include a warm water intake and outfall and a marine aggregates jetty extending offshore from the intertidal zone adjacent to the northern SSA boundary. The location of the outfall has not been confirmed but is likely to be at least 1km offshore from the existing Hinkley site. Modelling work undertaken to determine the most suitable location for the outfall indicates that the warm water plume emitted from the outfall, is likely to drift onto mudflats to the east of the SSA. The location of the study area for the 2010-11 intertidal surveys has been informed by this modelling work, and incorporates mudflats and other intertidal habitat east of the SSA, between Hinkley Point and Stert Point.

[1] Extending as far inland as the east-west Green Lane (also a footpath) that runs along the ridge towards the middle of the SSA.

1.3 Study Area Description and Context

The study area comprises much of the Stert Flats and includes a 7km stretch of intertidal habitat between Hinkley Point and Stert Point. The extent of intertidal mudflats exposed at low water broadens in the east, being only 800m from Mean High Water at Hinkley Point, to at least 3km offshore between Wall Common and Stert Point. A narrow band of saltmarsh (50-150m wide) runs along the high water mark along much of the length of the study area, from Stolford to Stert Point, with two large intertidal rock platforms located at Hinkley Point and Stolford. Immediately south of this (on the landward side of the Stert Flats) are Catsford Common and Wall Common (areas of rough, unimproved grassland and scrub) and open farmland (comprising both pasture and arable) interspersed by water-filled ditches. There are no major rivers flowing into the intertidal habitat within the study area, although immediately to the east of the study area is the mouth of the Parrett River.

Within the wider area, the Stert Flats form much of the intertidal mudflats of Bridgwater Bay, west of the Parrett River estuary, extending east to the beach front of Burnham-on-Sea. Bridgwater Bay (including the Stert Flats and Parrett Estuary) form a substantial part of the intertidal habitat resource of the Severn Estuary. Bridgwater Bay is located in Somerset on the southern banks of the Severn Estuary along the lower reaches of the Bristol Channel.

1.4 Background and Scope

The key potential ornithological issues relating to the proposed warm water outfall at Hinkley are:

- Thermal regime change (caused by discharge of cooling water) leading to changes in the composition of intertidal benthic communities and the abundance and biomass of individual invertebrate prey species within them;
- The potential of the impact identified above to have significant adverse effects on the species that form the cited interest of the European and nationally designated sites adjacent to the planning application boundary.

There is no guidance available that details potentially appropriate methodologies for ornithological survey work aimed at informing EIA for new nuclear power station proposals. The bird survey programme for Hinkley has therefore been based on the results of previous desk study and bird surveys undertaken in the SSA, consultation with Natural England and RSPB and professional judgment. The potential for species protected under Schedule 1 of the Wildlife & Countryside Act 1981 (as amended)[2] and / or listed under Annex 1 of the EC Directive on the Conservation of Wild Birds (79/409/EEC), commonly referred to as the Birds Directive[3] to occur within the study area was the subject of specific investigation. Migratory water birds forming part of the featured interest of designated sites were also considered.

[2] All species of wild birds are afforded some degree of protection under the Wildlife and Countryside Act 1981 (as amended). Some species are considered to be rare or vulnerable and receive increased protection through their inclusion on Schedule 1 of the Act.

[3] Certain endangered, rare, or vulnerable bird species, which warrant special protection, are included on Annex 1 of the European Communities Council Directive on the Conservation of Wild Birds (79/409/EEC).

2. Methodology

2.1 Desk Study

To understand the ornithological context of the study area, the locations and qualifying features of Special Protection Areas (SPAs) and Sites of Special Scientific Interest (SSSIs) of ornithological importance within, or adjacent to the study area were determined through the use of the websites www.magic.gov.uk, www.jncc.gov.uk, www.naturalengland.org.uk, and other published sources. The location of these statutory designated sites is shown in **Figure 2.1**.

2.2 Bird Surveys

The key objective of the bird surveys undertaken on the Stert Flats in 2010-11 was to provide a suitable baseline for the evaluation of the potential effects of the warm water plume on the intertidal bird communities present in the area, and in particular the effects on those species that form the qualifying interest of the Severn Estuary SPA and Ramsar site.

2.2.1 Intertidal and Inshore Marine Bird Survey

In order to evaluate the level and type of use of the Stert Flats by waterfowl, intertidal and inshore marine bird surveys were undertaken on a regular basis, commencing in April 2010. Surveys were carried out from four observation points. The National Grid References of these are as follows:

- ST 223 459;
- ST 241 456;
- ST 253 453;
- ST 265 457.

The entire study area was divided into a 200m by 200m square grid system. The observation points and the grid area are shown on **Figure 1.1**. Each 1km square was assigned a unique number (1-21), within which, each 200m square was assigned a unique letter (A-N and P-Z). Due to the distance from the nearest observation point to the 1km squares numbered 1-7 (i.e. greater than 1km) very few birds were recorded in these squares. However, for completeness, records from all the 21 1km squares have been included.

In order to describe the type of habitats visible from each observation point, the study area has for ease of description been divided into four areas, those areas visible from each observation point (Count Sectors 1-4 respectively). The area within each count sector approximately equates to that within the following 1km grid square numbers:

- Count Sector 1: 1km grid squares 1, 2, 8, 9, 15 and 16;
- Count Sector 2: 1km grid squares 3, 4, 10, 11, 17 and 18;

- Count Sector 3: 1km grid squares 5, 12 and 19;
- Count Sector 4: 1km grid squares 6, 7, 13, 14, 20 and 21.

Table 2.1 describes the characteristics of the intertidal habitat within each Count Sector.

Table 2.1 Characteristics of the Shore from each Observation Point[4]

Count Sector	Description of Extent and Characteristics of Shore at Mean High Water	Description of Extent and Characteristics of Shore at Mean Low Water
1	Very little intertidal habitat is visible at Mean High Water	The mudflats extend for 600-800m at low water. The rock platform at Hinkley Point (in the west of the count sector) extends 600m from the mean high water mark. In the east of the count sector, the Stolford rock platform extends for 700m. Just below the high water mark between the two rock platforms is a narrow (30-50m wide) band of shingle beach.
2	A narrow band of shingle (20-60m wide) is visible at mean high water, inland of which is Catsford Common (rough grassland and scrub)	The extent of mudflats exposed at low water within the count sector broadens from 800m in the west to 3km in the east. The eastern edge of the Stolford rock platform is visible in the west of the count sector. Just below the high water mark, adjacent to the rock platform is a narrow band of shingle beach.
3	A narrow band of saltmarsh (up to 90m wide) is visible above the mean high water mark, behind which is farmland and Wall Common (rough grassland and scrub).	Up to 3.4km of mudflats extend offshore at low water of which 2.8km are included in the grid area.
4	A band of saltmarsh (150-200m wide) is visible at mean high water behind which is farmland and a number of farmsteads. The eastern end of the count sector extends towards Stert Point and Fenning Island.	Up to 3-4km of mudflats are exposed at low water, of which1.2-2.2km are included in the grid area.

The aim of the survey work was to record the numbers, diversity and activity of waterfowl present and to identify areas of importance for birds (in the intertidal zone and inshore marine waters) during the tidal cycle. On each survey day, surveys were conducted over six full hours from a particular observation point, so that any changes or patterns in bird distribution across the tidal cycle could be identified. During each six hour period, a series of 12 counts were undertaken at 30 minute intervals from the same observation point. Approximately 4-5 six-hour sessions were undertaken from each observation point each month.

During each count, the intertidal area and inshore waters were scanned using binoculars and a high-powered telescope, and all species of waterfowl (including swans, geese, ducks, grebes, cormorants, herons and waders) were recorded. The counts provide a ‘snapshot survey’ of the birds present at that particular time. All wildfowl using (i.e. foraging, resting, etc.) the intertidal habitat and the inshore waters within the grid area were systematically recorded. Numbers and apparent behaviour were noted and their 200m^2 grid square location recorded. The start times of the surveys were varied to incorporate a full range of the tidal cycle at each observation point.

[4] This basic summary of the dominant intertidal habitats within each sector is included here to inform the reader. A more formal and scientific description of the shore will be produced as part of the marine biological studies that will be an integral part of the EIA for the site.

A team of four surveyors were employed to survey the four observation points on a rotational basis over the survey period.

A total of 2,365 counts were undertaken on 123 survey dates between April 2010 and January 2011 inclusive, involving approximately 590 counts from each observation point. **Table 2.2** presents the dates on which surveys were undertaken.

Table 2.2 Intertidal and Inshore Marine Survey Dates from each Observation Point

3. Results

3.1 Designated Sites of Ornithological Importance

3.1.1 European Designated Sites

The intertidal habitat within the study area is located entirely within the Severn Estuary SPA. The SPA was classified on the basis of its wintering bird interest and for the large numbers of waterfowl that regularly use the site.

The SPA qualifies under Article 4.1 of the Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex 1 of the Directive:

Over winter:

- Tundra (Bewick's Swan) (*Cygnus columbianus bewickii*), 280 individuals representing approximately 3.9% of the wintering population in Great Britain (5 year peak mean 1991/2 – 1995/6).

The site also qualifies under Article 4.2 of the Directive by supporting populations of European importance of the following migratory species:

Over winter:

- Russian white-fronted goose (*Anser albifrons albifrons*), 2,664 individuals representing 0.4% of the North-western Siberian. North-eastern European and North-western European wintering population (5 year peak mean 1991/2 – 1995/6);
- Dunlin (*Calidris alpina alpina*), 44,624 individuals representing at least 3.2% of the wintering Northern Siberian, European and Western African population (5 year peak mean 1991/2 - 1995/6);
- Gadwall (*Anas strepera*), 282 individuals representing approximately 0.9% of the wintering North-west European population (5 year peak mean 1991/2 - 1995/6);
- Redshank (*Tringa totanus*), 2,330 individuals representing at least 1.6% of the wintering Eastern Atlantic population (5 year peak mean 1991/2 - 1995/6); and
- Shelduck (*Tadorna tadorna*), 3,330 individuals representing at least 1.1% of the wintering Northwestern Europe population (5 year peak mean 1991/2 - 1995/6).

The SPA also qualifies under **Article 4.2** of the Directive by regularly supporting at least 20,000 waterfowl:

> *"Over winter, the area regularly supports 93,986 individual waterfowl (5 year peak mean 1991/2 - 1995/6) including: Gadwall, Shelduck, Pintail, Dunlin, Curlew, Redshank, Bewick's Swan, Wigeon, Lapwing (Vanellus vanellus), Teal, Mallard (Anas platyrhynchos), Shoveler, Pochard, Tufted Duck (Aythya*

fuligula), Grey Plover (Pluvialis squatarola), White-fronted Goose and Whimbrel."

Subsequent to the publication of the data above (as included in the Natura 2000 Standard Data Form), the following changes have been suggested by the SPA Review (Stroud *et al.*, 2001):

Removal of the following species that originally qualified under Article 4.2 of the Directive:

- Russian white-fronted goose;
- Gadwall.

Addition of the following species that now qualify under Article 4.2 of the Directive by supporting populations of European importance:

- On passage:
  - Ringed Plover *Charadrius hiaticula*, 655 individuals representing at least 1.3% of the Europe/Northern Africa wintering population (5 year peak mean 1991/2 – 1995/6).
- Over winter:
  - Curlew *Numenius arquata*, 3,903 individuals representing at least 1.1% of the wintering European population (5 year peak mean 1991/2 – 1995/6);
  - Pintail *Anas acuta*, 599 individuals representing at least 1.0% of the wintering Northwestern Europe population (5 year peak mean 1991/2 – 1995/6).

The SPA Review has yet to be formally adopted, although in practice SPA Review information (regarding additional species) is given the same credence by nature conservation consultees as that contained on the Natura 2000 Data Sheets.

3.1.2 Internationally Designated Sites

The intertidal habitat within the study area is located entirely within the Severn Estuary Ramsar Site, which shares a common boundary with the Severn Estuary SPA and Bridgwater Bay SSSI in this location (ref **Figure 2.1**). The Severn Estuary qualifies as a Ramsar site under Criterions 5 and 6 of the Ramsar Convention due to the internationally important bird assemblage and individual populations that occur.

Qualifying ornithological interest listed on the Ramsar Information Sheet is summarised as follows:

- During winter the site supports an assemblage of 70,919 waterfowl (5 year peak mean 1998/99-2002/03).

Under Criterion 6, during the winter the site supports internationally important numbers of:

- Tundra (Bewick's) swan (*Cygnus columbianus bewickii*), 229 individuals representing an average of 2.8% of the GB population (5 year peak mean 1998/99-2002/03);
- Greater white-fronted goose (*Anser albifrons*), 2,076 individuals representing an average of 35.8% of the GB population (5 year peak mean for 1996/97-2000/01);

- Common shelduck (*Tadorna tadorna*), 3,223 individuals representing an average of 1% of the north-western European population (5 year peak mean 1998/99-2002/03);
- Gadwall (*Anas strepera strepera*), 241 individuals representing an average of 1.4% of the GB population (5 year peak mean 1998/99-2002/03);
- Dunlin (*Calidris alpina alpina*), 25,082 individuals representing an average of 1.8% of the Western Siberian / Western European population (year peak mean 1998/99-2002/03);
- Redshank (*Tringa totanus totanus*), 2,616 individuals representing an average of 1% of the population (5 year peak mean 1998/99-2002/03).

Species identified on the Ramsar Information Sheet for possible future consideration under Criterion 6 are as follows:

- Lesser black-backed gull (*Larus fuscus graellsii*), a breeding season population of 4,617 apparently occupied nests, representing an average of 2.8% of the breeding population (Seabird 2000 Census);
- Ringed plover (*Charadrius hiaticula*), 740 individuals representing an average of 1% of the European / North-west African passage population (5 year peak mean 1998/99-2002/03);
- Teal (*Anas crecca*), 4,456 individuals representing an average of 1.1% of the north-west European wintering population year (5 peak mean 1998/99-2002/03);
- Pintail (*Anas acuta*), 756 individuals representing an average of 1.2% of the population (5 year peak mean 1998/99-2002/03).

In addition to these species currently and potentially forming the cited interest of the Ramsar Site, a number of species occur at nationally important levels during the breeding season, passage periods and over winter. These are:

- Herring gull (*Larus argentatus argentatus*), 1,540 apparently occupied nests, representing an average of 1.1% of the GB breeding population (Seabird 2000 Census);
- Little egret (*Egretta garzetta*), 17 individuals, representing an average of 1% of the GB passage population (5 year peak mean 1998/9-2002/3);
- Ruff (*Philomachus pugnax*), 12 individuals, representing an average of 1.7% of the GB passage population (5 year peak mean 1998/9-2002/3);
- Whimbrel (*Numenius phaeopus*), 333 individuals, representing an average of 11.1% of the GB passage population (5 year peak mean 1998/9-2002/3);
- Curlew (*Numenius arquata arquata*) 2,021 individuals, representing an average of 1.3% of the GB passage population (5 year peak mean 1998/9-2002/3);
- Common greenshank (*Tringa nebularia*), 26 individuals, representing an average of 4.3% of the GB passage population (5 year peak mean 1998/9-2002/3);

- Wigeon (*Anas penelope*), 4,658 individuals, representing an average of 1.1% of the GB wintering population (5 year peak mean 1998/9-2002/3);
- Northern shoveler (*Anas clypeata*) 297 individuals, representing an average of 2% of the GB wintering population (5 year peak mean 1998/9-2002/3);
- Common pochard (*Aythya farina*) 1,118 individuals, representing an average of 1.8% of the GB wintering population (5 year peak mean 1998/9- 2002/3);
- Water rail (*Rallus aquaticus*), 11 individuals, representing an average of 2.4% of the GB wintering population (5 year peak mean 1998/9-2002/3);
- Spotted redshank (*Tringa erythropus*) 10 individuals, representing an average of 7.3% of the GB wintering population (5 year peak mean 1998/9-2002/3).

In addition to the bird interest the site has also been designated for extensive areas of intertidal sand and mudflats, intertidal rock platforms, vegetated shingle beach and maritime grasslands with freshwater and brackish ditches, which support nationally important plant species. Sea lamprey (*Petromyzon marinus*) occurs at the site at an internationally important level.

3.1.3 Nationally Designated Sites

The intertidal habitat within the study area is located entirely within the Bridgwater Bay SSSI which covers a total area of 3,574ha (35.74km^2). Its position is shown on **Figure 2.1**.

The SSSI is of national importance for the succession of habitats it supports. These include intertidal mud, wave-cut platforms, cliffs, sand dunes, shingle ridges and extensive areas of saltmarsh. Associated with these habitats are internationally and nationally important assemblages of wintering and passage migrant waders and waterfowl, and a diverse invertebrate fauna. The SSSI supports internationally important numbers of passage whimbrel[5] and black-tailed godwit (*Limosa limosa*) and nationally important numbers of overwintering dunlin and wigeon. Shelduck use the bay as a moulting ground, and are also present in nationally important numbers.

The Severn Estuary is used by internationally important numbers of dunlin, shelduck, wigeon, curlew, redshank and teal and nationally important numbers of ringed plover and grey plover. Knot (*Calidris canutus*), turnstone (*Arenaria interpres*), snipe (*Gallinago gallinago*) and mallard also occur. Bridgwater Bay SSSI is used by a substantial proportion of the overall waterfowl and wader populations of the Severn Estuary. The SSSI is also ecologically linked to the Somerset Levels, which provide additional winter-feeding grounds for large numbers of waders and wildfowl.

[5] The information contained in the SSSI site description is dated, and for black-tailed godwit may never have been wholly accurate. Since the early 1980s there has been a decline in the whimbrel population using Bridgwater Bay. It is possible that birds have moved to other locations within the estuary, but the precise reason for the decline is unknown. It remains of national importance (Archer, *in litt*). Black-tailed godwit numbers, in contrast, are increasing at regional and national level. This is due to the success of the Icelandic breeding population, and numbers of birds using the area on autumn passage regularly exceed the threshold of national importance, while winter numbers are also approaching this threshold (Archer, *in litt*).

3.2 Intertidal and Inshore Marine Bird Surveys

Intertidal and inshore marine surveys conducted between April 2010 and January 2011 inclusive (the survey period) resulted in a total of 16 species of wildfowl, 19 species of wader and 6 additional species of seabird and water bird being recorded. A summary account of the type and level of use of the study area by each species that appears as designated or cited interest of the Severn Estuary SPA/Ramsar site and/or Bridgwater Bay SSSI is provided below. The peak and mean monthly counts recorded (for all species) from each observation point are presented in **Table A1** in **Appendix A**. The peak counts (sum of all counts) recorded in each 200m grid square between April 2010 and January 2011 inclusive are shown in **Figures 3.1a-p**, for shelduck, wigeon, gadwall, teal, mallard, pintail, shoveler, tufted Duck, ringed Plover, grey plover, lapwing, dunlin, black-tailed godwit, whimbrel, curlew and redshank respectively.

3.2.1 Qualifying / Assemblage Species

Of the species that appear as designated features of the Severn Estuary SPA; gadwall, shelduck, dunlin and redshank were recorded during the intertidal surveys undertaken between April 2010 and January 2011, but not Bewick's swan or white-fronted goose. Ringed plover, curlew and pintail (which appear in the SPA Review) were noted. Teal, wigeon, mallard, shoveler, tufted duck, lapwing, grey plover and whimbrel which are listed in the waterfowl assemblage qualification for the SPA were recorded, but not pochard. Black-tailed godwit, which appears as a cited feature of the Bridgwater Bay SSSI was also recorded.

Shelduck *(Tadorna tadorna)* [SPA, Ramsar & SSSI Qualifying Species]
Shelduck were recorded in the study area on all 123 survey dates between April 2010 and January 2011 inclusive, with the largest numbers generally seen between late July and early November, including a peak count of 2,049 foraging and loafing birds from observation point 4 on 31 August. Foraging shelduck were widely distributed across the intertidal habitat within the study area (see **Figure 3.1a**). Large counts included 1,670 birds foraging on mudflats, offshore between Catsford Common and Wall Common on 26 October, with 1,520 birds there on 26 September. Other counts in excess of 1,000 birds were noted on mudflats between Hinkley Point and Stolford, and in the east of the study area, offshore of Stert village. Large congregations of roosting shelduck were also noted at a number of locations, including 450 birds on rocks at Stolford on 31 August, and 425 on nearby mudflats on 30 September. Further west, 206 shelduck were roosting on rocks at Hinkley Point on 31 August, with 400 on nearby mudflats on 17 October. The largest numbers of foraging birds were present on the tidal mudflats at low water, with birds moving off these areas, with incoming water, to loaf on the sea or roost on the upper reaches of the shoreline, including on the rock platforms at Stolford and Hinkley Point. Numbers of shelduck in excess of 1% of the Severn Estuary SPA qualifying population of this species (3,330 birds) were recorded from observation points 1-4, on 46, 47, 45 and 39 survey dates respectively.

Wigeon (*Anas penelope*) [SPA Assemblage and SSSI Qualifying Species]
Wigeon were recorded in the study area on 37 (of 123) survey dates, with the first birds seen on 20 September 2010. Wigeon were widely distributed across the study area (see **Figure 3.1b**), with the largest numbers seen in November-January, and a peak count of 312 birds seen from observation point 1 on 24 January. Numbers however were generally much lower than this, with total counts from each observation point generally in the region of 20-100 birds. Small groups of wigeon were seen foraging along creeks and in the shallows along the shoreline

throughout the study area. Flocks of roosting wigeon were more infrequently seen, with the largest being 211 birds on mudflats between Hinkley Point and Stolford on 20 January. Numbers of wigeon in excess of 1% of the Severn Estuary population of this species (8,466 birds, Calbrade *et al.*, 2010) were recorded from observation points 1-4, on 4, 3, 1 and 0 survey dates respectively.

Gadwall (*Anas strepera*) [SPA and Ramsar Qualifying Species]

Gadwall were recorded on two survey dates, involving one bird loafing on mudflats offshore of Wall Common on 16 November, and two loafing on mudflats between Hinkley Point and Stolford on 30 December (see **Figure 3.1c**). Numbers of gadwall in excess of 1% of the Severn Estuary SPA qualifying population of this species (282 birds) were not recorded from any observation point during the intertidal surveys.

Teal (*Anas crecca*) [SPA Assemblage and Possible Future Ramsar Site Qualifying Species, SSSI Qualifying Species]

Teal were recorded on seven survey dates (six of which were in December 2010). The peak count was of 27 teal loafing on the upper shore, between Hinkley Point and Stolford on 30 December. However, most records were of 1-5 birds either loafing or roosting on the upper shoreline, or foraging in mudflat creeks (see **Figure 3.1d**). Numbers of teal in excess of 1% of the Severn Estuary population of this species (4,916 birds, Calbrade *et al.*, 2010) were not recorded from any observation point during the intertidal surveys.

Mallard (*Anas platyrhynchos*) [SPA Assemblage Species]

Mallard were recorded on 84 (of 123) dates throughout much of the survey period, although the largest numbers were most consistently recorded between August and January, and the lowest numbers in April and May. There was a clear bias towards the western half of the study area, with very few mallard noted from observation point 4 in the east (see **Figure 3.1e**). The largest count of mallard was of 87 birds roosting on rocks at Hinkley Point on 31 August, and other groups of roosting birds were noted at various locations on the mudflats and rocks around Hinkley and Stolford. The largest numbers of foraging birds were seen on mudflats between Hinkley Point and Wall Common, including 40 offshore from Wall Common on 27 September. Numbers of mallard in excess of 1% of the Severn Estuary population of this species (3,385 birds, Calbrade *et al.*, 2010) were recorded from observation points 1-4, on 2, 10, 0 and 0 survey dates respectively.

Pintail (*Anas acuta*) [SPA Review and Possible Future Qualifying Ramsar Site Species]

Pintail were recorded on a total of 67 (of 123) survey dates between April 2010 and January 2011. Up to two birds were seen at various locations within the study area between 19 April and 9 June, after which none were seen until 31 August. Larger numbers of pintail were then seen from late September until the end of the survey period in January. The largest numbers of pintail were recorded most consistently from October to December, with a peak total of 158 birds seen from observation point 3 on 14 December. There was a bias of records towards the west and centre of the study area, with few pintail seen from observation point 4 in the east (see **Figure 3.1f**). In the west of the study area, groups of pintail were seen foraging on the mudflats, or loafing and roosting on the upper reaches of the shoreline and rock platforms at various locations. Large counts of pintail included 135 loafing on mudflats between Hinkley Point and Stolford on 13 December, and 130 foraging on mudflats near Stolford on 14 December. Numbers of pintail in excess of 1% of the Severn Estuary SPA Review population of this species (599 birds) were recorded from observation points 1-4, on 21, 18, 12 and 0 survey dates respectively.

Shoveler (*Anas clypeata*) [SPA Assemblage]

Shoveler were recorded on a total of 10 (of 123) survey dates between April 2010 and January 2011 inclusive. A single bird was seen from observation point 4 on 28 July, followed by 90 birds loafing on mudflats between Catsford and Wall Commons on 18 November. These records were then followed by a scattering of sightings of 1-3 birds across the study area from 30 November to 31 December (see **Figure 3.1g**). Numbers of shoveler in excess of 1% of the Severn Estuary population of this species (561 birds, Calbrade *et al.*, 2010) were recorded on one survey date (from observation point 3).

Tufted Duck (*Aythya fuligula*) [SPA Assemblage]

One or two tufted ducks were seen on four surveys dates, loafing or foraging in creeks between Hinkley Point and Stert village, on 28 July, 8 and 17 October and 5 December (see **Figure 3.1h**).

Ringed Plover *(Charadrius hiaticula)* [SPA Review and Possible Future Qualifying Ramsar Site Species]

Ringed plovers were recorded on 64 (of 123) survey dates between April 2010 and January 2011, although there were a number of periods when the species was not seen for several consecutive survey dates. The largest numbers of ringed plovers were seen in April-June and in August, although the intertidal habitat viewed from observation point 2 held high numbers of birds until November, and relatively few birds were seen in the west of the study area from observation point 1. In general, up to 70 ringed plover were counted in the study area on most survey dates, primarily on mudflats between Stolford and Stert village in the east of the study area (see **Figure 3.1i**). However, on two consecutive dates (16 and 17 August) very large numbers of ringed plover (378 and 702 birds respectively) were seen in the east of the study area. On 16 August, a flock of 350 ringed plover were foraging on mudflats offshore of Stert village, and on the following day, 687 birds were counted there. Much smaller numbers of roosting ringed plover were seen, with the largest count being on 40 birds on the shingle beach between Catsford and Wall Commons on 19 April. This site was used infrequently however, and nowhere within the study area held more than 20 birds on a regular basis. Numbers of ringed plover in excess of 1% of the Severn Estuary SPA Review population of this species (655 birds) were recorded from observation points 1-4, on 4, 18, 15 and 17 survey dates respectively.

Grey Plover *(Pluvialis squatarola)* [SPA Assemblage Species]

Grey plover were recorded on a total of 71 (of 123) survey dates between April 2010 and January 2011 inclusive. Birds were primarily seen during two periods, with very small numbers of grey plover (maximum of 7 birds) recorded during spring passage in April and May, and much larger numbers during autumn passage and winter, from September onwards. The largest numbers of grey plover were counted from October to January, with a peak count of 975 birds seen from observation point 4 on 18 November. There was a clear bias towards the eastern half of the study area, with relatively few birds seen on the mudflats in the west, between Hinkley Point and Stolford (see **Figure 3.1j**). Other large counts of grey plover included 890 foraging on mudflats offshore of Wall and Catsford Commons on 19 November, and 590 foraging offshore of Stert village on 3 October. Large congregations of roosting grey plover were seen at high tide on the saltmarsh and adjacent mudflats, offshore of Stert village, with 200 birds there on 12 November. The shingle beach and mudflats adjacent to Wall and Catsford Commons were also favoured areas for roosting grey plovers, albeit in smaller numbers (up to 70 birds). Numbers of grey plover in excess of 1% of the Severn Estuary population of this species (416 birds, Calbrade *et al.*, 2010) were recorded from observation points 1-4, on 0, 7, 19 and 26 survey dates respectively.

Lapwing (*Vanellus vanellus*) [SPA Assemblage Species]

Lapwing were recorded on a total of 24 (of 123) survey dates between April 2010 and January 2011 inclusive. Birds were seen from 26 September to 28 January and were recorded from all observation points (see **Figure 3.1k**). The largest number of lapwings were recorded from October to January, with a peak count of 412 loafing and foraging birds on mudflats and adjacent shingle from observation point 3 (i.e. between Catsford and Wall Commons) on 19 December. This was followed by 209 birds in the same area on 21 December. Apart from the two counts in December, foraging lapwing were seen infrequently in the study area. Small groups of up to 45 roosting lapwing were seen at various locations in the study area, on mudflats and on the upper reaches of the shoreline. Numbers of lapwing in excess of 1% of the Severn Estuary population of this species (15,693 birds, Calbrade *et al.*, 2010) were recorded on two survey dates, both from observation point 3.

Dunlin (*Calidris alpina*) [SPA, Ramsar Site and SSSI Qualifying Species]

Dunlin were recorded on a total of 99 (of 123) survey dates between April 2010 and January 2011 inclusive. Birds were seen throughout much of the survey period, with by far the largest numbers occurring during winter, from October onwards. There was again, a clear bias towards the eastern half of the study area, with very large numbers of dunlin recorded on the mudflats east of Stolford, and relatively few around Hinkley Point (see **Figure 3.1l**). The largest count was of 12,590 dunlin, which were seen from observation point 4 on 31 December, and numbers in excess of 5,000 birds were noted on a further seven survey dates from observation point 4, and on two dates from observation point 3. Overall, flocks of 1,000 or more dunlin were seen on a frequent basis during winter, foraging on the mudflats east of Stolford. Congregations of roosting dunlin at high tide were also seen at a number of locations at high tide, included 860 birds on mudflats adjacent to Wall and Catsford Commons on 28 December, and 700 on the saltmarsh by Stert village on 12 November. Numbers of dunlin in excess of 1% of the Severn Estuary SPA qualifying population of this species (44,624 birds) were recorded from observation points 1-4, on 0, 13, 19 and 20 survey dates respectively.

Black-tailed Godwit (*Limosa limosa*) [SSSI Qualifying Species]

Black-tailed godwits were recorded on 27 (of 123) survey dates between April 2010 and January 2011 inclusive. This species was seen infrequently throughout much of the survey period, although there was a concentration of records during the period from 10 August to 14 October (the autumn passage period), and there was a bias of sightings towards the eastern half of the study area (see **Figure 3.1m**). Black-tailed godwits were seen on one survey date during the spring passage period (April-May) involving nine birds foraging on mudflats between Hinkley Point and Stolford on 18 May. The species was also seen infrequently during the winter period covered by the surveys (November-January), with up to 14 birds noted on five survey dates. During the autumn passage period (July-October) the largest counts of black-tailed godwit were recorded in September, with up to 160 birds foraging on mudflats offshore between Catsford and Wall Commons, and up to 125 on mudflats off Stert village. Very few black-tailed godwits were recorded in the study area west of Stolford and very few roosting birds were seen. Numbers of black-tailed godwit in excess of 1% of the Bridgwater Bay population of this species (226 birds[6]) were recorded from observation points 1-4, on 3, 1, 5 and 12 survey dates respectively.

Whimbrel *(Numenius phaeopus)* [SPA Assemblage and SSSI Qualifying Species]

Whimbrel were recorded on 37 (of 123) survey dates between April 2010 and January 2011 inclusive. Birds were seen during two periods, with much larger numbers noted during spring passage (April to early June) than autumn passage (July to September). During the spring passage period, whimbrel were recorded on all but one survey date between 19 April (the start of the survey) and 11 June. Large numbers of whimbrel were recorded in April, with a total of 254 birds counted in the entire study area on 21 April, 173 birds on 22 April and 115 on 23 April (surveys were undertaken from all observation points on these dates). Smaller numbers of whimbrel were recorded during May and early June (generally 10-20 birds). Flocks of foraging whimbrel were widely distributed across much of the mudflats in the study area (see **Figure 3.1h**). A total of 104 whimbrel were seen foraging on mudflats just east of Stolford on 21 April, and counts of 20-30 birds were noted off Stert village, also during late April. The mudflats between Hinkley Point and Stolford rock platform were also used by good numbers of foraging whimbrel, with a peak count of 43 birds there on 22 April. Groups of roosting birds at high tide were primarily seen in April, with very few noted thereafter. No regular roosting areas were identified during the surveys, with the only count in excess of ten birds being 46 on the saltmarsh and mudflats adjacent to Stert village on 23 April. Returning whimbrel were first seen on 19 July after which generally 5-10 birds were noted regularly until the last record on 14 September. Numbers of whimbrel in excess of 1% of the Severn Estuary population of this species (171 birds, Calbrade *et al.*, 2010) were recorded from observation points 1-4, on 15, 12, 15 and 14 survey dates respectively.

Curlew *(Numenius arquata)* [SPA Review Qualifying Species, Potential Future Ramsar Qualifying Species]

Curlew were recorded on all but one of the 123 survey dates between April 2010 and January 2011 inclusive. During spring passage, curlew were seen in April (generally 20-40 birds on mudflats between Stolford and Stert village), with numbers declining in May to 5-10 birds from each observation point. The largest numbers of curlew were however recorded from July to January, during the autumn passage and winter periods, covered by the surveys. There was a bias towards the eastern half of the study area (see **Figure 3.1o**), with counts exceeding 500 birds noted from observation points 3 and 4 during November and December, including a peak count of 739 birds from observation point 4 on 28 December. The largest numbers of foraging birds were seen on mudflats offshore of Catsford and Wall Commons (peak count of 400 birds on 26 September) and on mudflats adjacent to Stert village (peak count of 706 on 28 December). Much smaller numbers of curlew were seen foraging on mudflats around Hinkley Point (generally up to 10 birds), and Stolford (generally, 10-30 birds). Notable congregations of roosting and loafing birds at high tide were seen on the saltmarsh and adjacent mudflats next to Stert village (110 birds on 27 January) and on the shingle and mudflats adjacent to Catsford Common, including 229 birds on 22 October. Roosting birds were more infrequently recorded on the rocks and surrounding mudflats at Hinkley Point, where generally 1-10 birds were noted. Numbers of curlew in excess of 1% of the Severn Estuary SPA Review population of this

[6] This figure is derived from the peak monthly count on the Parrett Estuary in 2008 (Gibbs [ed], 2010)

species (3,903 birds) were recorded from observation points 1-4, on 0, 30, 33 and 31 survey dates respectively.

Redshank *(Tringa totanus)* [SPA and Ramsar Site Qualifying Species]
Redshank were recorded on 56 (of 123) survey dates between April 2010 and January 2011 inclusive. Very few redshank were seen during the spring passage period (primarily in April), with 1-4 birds seen on two survey dates. This was followed by infrequent records of 1-5 birds, until 3 October when a total of 355 redshank were counted from observation point 4. Between 10 November and the end of the survey period on 31 January, redshank were recorded more regularly in larger numbers, with counts exceeding 100 birds noted on six survey dates. There was a bias of records towards the eastern half of the study area, with by far the largest numbers seen from observation points 3 and 4 (from October to January). Much smaller numbers (generally 1-10 birds) were counted from observation points 1 and 2. The largest numbers of foraging redshank were seen on mudflats offshore of Catsford and Wall Commons (peak count 166 birds on 18 November) and Stert village (peak count of 310 birds on 3 October). The mudflats between Hinkley Point and Stolford held much smaller numbers of foraging redshank, generally 1-10 birds in the winter. Small groups of loafing and roosting redshank were seen at high tide at a number of locations, with the largest numbers recorded on the shingle and adjacent mudflats at Stolford (peak count 20 birds on 14 December) and the mudflats and saltmarsh adjacent to Stert village (peak count of 15 birds on 3 October). Numbers of redshank in excess of 1% of the Severn Estuary SPA qualifying population of this species (2,330 birds) were recorded from observation points 1-4, on 0, 0, 6 and 11 survey dates respectively.

3.2.2 Non-Cited Species

A range of species that do not appear as designated or cited features of the Severn Estuary Ramsar/SPA or Bridgwater Bay SSSI were recorded during the intertidal surveys undertaken between April 2010 and January 2011 inclusive. A brief summary account of use of the study area by each species that were recorded is provided below.

Wildfowl
A further eight species of wildfowl (swans, geese and ducks) that do not appear as designated features of the Severn Estuary SPA/Ramsar site were recorded in the study area, as follows:

- Mute swan (*Cygnus olor*). Up to five foraging and loafing birds were seen on seven survey dates (between Hinkley Point and Wall Common), on 19 April, 22 and 28 July, 24 August, 14 October and 18 November;

- Greylag goose (*Anser anser*). Four birds were seen loafing on mudflats between Catsford and Wall Commons on 18 November;

- Canada goose (*Branta canadensis*). Two birds were seen loafing in the study area on 10 June;

- Brent goose (*Branta bernicla*). A flock of brent geese, probably involving up to 17 birds was seen regularly (on 31 survey dates) from 11 October to 30 January. These birds were seen foraging and loafing on mudflats between Hinkley Point and Wall Common. The flock contained similar numbers of both pale-bellied (*B. b. hrota*) and dark-billed (*B. b. bernicla*) race birds;

- Scaup (*Aythya marila*). A flock of up to 11 birds were seen foraging and loafing on the sea (from Hinkley Point to Stert village), close inshore on nine survey dates between 13 November and 26 January;
- Eider (*Somateria mollissima*). A single bird was seen loafing on the sea close inshore, around Hinkley Point on three survey dates: 5 and 10 December, and 17 January;
- Common scoter (*Melanitta nigra*). A flock of eight birds were seen loafing on the sea at high tide on 23 July. This record was followed by 1-2 birds on the sea between Hinkley and Wall Common, on three survey dates from October to January, and a larger count of 26 loafing birds offshore between Hinkley and Stolford on 5 December;
- Goosander (*Mergus merganser*). Four birds were seen loafing on the mudflats between Catsford Common and Wall Common on 19 December (during a period of very cold weather conditions).

Waders

A further 11 species of wader that do not appear as qualifying interest of the Severn Estuary SPA/Ramsar site or cited interest of the Bridgwater Bay SSSI were recorded in the study area, as follows:

- Oystercatcher (*Haematopus ostralegus*) were recorded on 117 (of 123) survey dates, with the largest numbers seen in August during the autumn passage period. Large numbers of oystercatchers were recorded foraging on the mudflats between Hinkley Point and Wall Common (from observation points 1-3), which much smaller numbers in the east of the study area, offshore from Stert village (from observation point 4). During the spring passage period (April-May), 20-40 birds were generally counted in each of the areas surveyed from observation points 1, 2 and 3. Numbers remained at this level during the early part of the autumn passage period (June-July), but then increased greatly in August, when numbers regularly exceeding 100 birds on each visit. Numbers then declined in September, and remained at similar levels during winter, when 20-60 birds were counted on most visits. Large groups of loafing and roosting oystercatchers were seen at high tide at a number of locations, including on the rocks around Hinkley Point, where 504 birds were counted on 31 August, although numbers here were usually much lower (10-20 birds). The most regularly used roosting site was however on the shingle and mudflats adjacent to Wall and Catsford Commons, where 20-50 birds were frequently seen, with a peak count of 176 birds on 25 August. The rocks and adjacent mudflats by Stolford also regularly held 20-40 loafing and roosting oystercatchers;
- Golden plover (*Pluvialis apricaria*) were recorded in the study area infrequently (on ten survey dates from 29 July to 13 December 2010). Golden plover were recorded on five surveys dates from 16 and 24 November, primarily on intertidal habitat by Stert village Numbers were generally small, but occasionally larger groups of golden plover were noted, including a flock of 500 birds roosting on mudflats off Stert village on 3 October, with 400 there on 24 November. Golden

plover were seen loafing on the mudflats between Hinkley and Stolford on two survey dates, involving 4 and 6 birds repectively;

- Knot (*Calidris canutus*) were recorded on 51 (of 123) survey dates. Small numbers of knot were seen sporadically from May until the end of August after which numbers increased and birds were seen regularly, with a peak count of 3,575 birds counted from observation point 4 on 24 November. Large numbers of knot were recorded foraging on the mudflats west of Stolford from October to January, when numbers exceeding 1,000 birds on a regular basis. The mudflats offshore between Stolford and Wall Common and adjacent to Stert village held large numbers of foraging knot, with peak counts of 2,100 birds on 18 November and 2,425 birds on 24 November at each site respectively. Knot were recorded on only one survey date on mudflats between Hinkley Point and Stolford, involving three birds. Flocks of roosting and loafing knot were seen on the shingle beach and adjacent mudflats between Catsford and Wall Commons (peak count of 450 birds on 28 December), and on the mudflats and saltmarsh adjacent to Stert village (peak count of 740 on 26 November);

- Sanderling (*Calidris alba*) were recorded on a total of nine survey dates, during two periods. Up to five sanderlings were seen feeding on intertidal habitat between Stolford and Stert village on three dates in May. During the return autumn passage period, 1-3 foraging birds were seen in the same area on six dates between 29 July and 29 August;

- Little stint (*Calidris minuta*). A single bird was seen foraging on mudflats adjacent to Stert village on 12 October;

- Ruff (*Philomachus pugnax*). A single bird was seen foraging on mudflats adjacent to Stert village on 8 October;

- Snipe (*Gallinago gallinago*). Single birds were seen on intertidal habitat between Catsford and Wall Commons on 18 November and at Hinkley Point on 15 December;

- Bar-tailed godwit (*Limosa lapponica*) was recorded on 26 (of 123) survey dates between April 2010 and January 2011. Birds were seen during the spring passage period (April to early June), when 10-30 birds were foraging on mudflats, primarily between Stolford and Stert village. The first return autumn passage birds were seen on 17 August, and relatively large numbers of bar-tailed godwits were then recorded in the east of the study area until 13 October. During this autumn passage period, peak counts included 170 foraging bar-tailed godwits on mudflats between Catsford and Wall Commons on 17 September, and 175 loafing on mudflats adjacent to Stert village also on 17 September (feasibly the same flock of birds). Bar-tailed godwits were rarely seen west of Stolford (on a total two survey dates);

- Common sandpiper (*Actitis hypoleucos*). One bird was seen foraging on the edge of Catsford Common on 14 September;

- Greenshank (*Tringa nebularia*) were recorded on six survey dates from 19 July to 29 August (during the autumn passage period), mostly involving 1-2 birds foraging on mudflats between Stolford and Stert village;

- Turnstone (*Arenaria interpres*) were recorded on 67 (of 123) survey dates, primarily during the spring passage (April-May) and autumn passage and winter (August-January) periods covered by the surveys. The largest numbers of turnstone were recorded in the eastern half of the study area from October to January, when 20-40 birds were generally seen from each of observation points 2, 3 and 4. The favoured areas for foraging birds were on the shoreline and mudflats between Catsford and Wall Commons (peak count of 62 birds on 12 October), the mudflats around Stolford (peak count of 50 birds on 19 January), and Stert village (peak count of 45 birds on 24 January). Similar numbers of roosting turnstone were seen at high tide in the same areas, with the largest count being of 90 birds on intertidal habitat between Catsford and Wall Commons on 26 January. Turnstone were seen infrequently in and in very low numbers on the rocks and adjacent mudflats around Hinkley Point (1-6 birds).

Other Waterfowl and seabirds

A further five species of water bird and seabirds, that do not appear as qualifying interest of the Severn Estuary SPA/Ramsar site were recorded in the study area, as follows:

- Great Crested Grebe (*Podiceps cristatus*). One bird was seen loafing on the sea between Catsford and Wall Commons on 8 July;

- Cormorant (*Phalacrocorax carbo*). Cormorants were seen loafing on the rocks at Hinkley Point and foraging on the surrounding sea on a reasonably regular basis (on a total of 31 survey dates) throughout much of the survey period. A peak count of four birds was recorded at Hinkley Point on 31 August, with five birds seen from observation point 4 on 16 September;

- Little egret (*Egretta garzetta*) were recorded on 88 (of 123) survey dates between April 2010 and January 2011 inclusive, with the largest numbers seen from April to October. During this period, counts of 10-20 birds were regularly recorded from each of observation points 2, 3 and 4. The largest numbers were on the wider mudflats found in the eastern two-thirds of the study area, with a peak count of 44 birds recorded from observation point 4 on 17 August. Numbers declined to 1-2 birds during November, and the species disappeared from the area altogether (apart from one record of two birds on 19 January) from late November until the end of the survey period (probably due to the extremely cold weather experienced in late November and December). The largest numbers of foraging little egrets were seen in the mudflat creeks between Stolford and Stert village, with the area offshore of Catsford and Wall Commons supporting 10-25 birds during the spring and summer (a peak count of 38 birds was noted there on 8 June). Groups of loafing and roosting little egret were most numerous on the mudflats and shingle between Catsford and Wall Commons, with a peak count of 22 birds there on 17 August. The mudflats and rocks at Hinkley Point held much smaller numbers of little egret, generally 1-2 birds during spring and summer;

- Grey heron (*Ardea cinerea*). Up to four birds were seen on a regular basis throughout the survey period, foraging in creeks and along the shoreline throughout much of the study area;

- Little tern (*Sternula albifrons*). Two birds were seen loafing on the rocks at Hinkley Point on 20 April.

4. Discussion

When considering bird populations during the spring and autumn passage and winter periods, the threshold of importance (or significance) in population terms, is often taken as 1% of the (peak) number of a species known to occur within a given area. From this starting point, taking into account regularity and nature of use, it is possible to undertake a subjective analysis of the importance of an area to a bird species. The first step towards doing this for the intertidal study area between Hinkley Point and Stert Point, is to define the relevant areas. In the discussion that follows, the local area has been taken as Bridgwater Bay and the immediate surrounding land, while the county is Somerset and the region is that covered in The Southwest Biodiversity Implementation Plan[7]. National refers to the United Kingdom and International to World distribution (of the bird species or race of that species concerned).

Numbers of those species (recorded in the study area) that form part of the designated or cited interest of local statutory sites (in this case, the Severn Estuary SPA and Ramsar site, and the Bridgwater Bay SSSI) have been considered important if found to exceed 1% of the qualifying number listed in any of these site citations. To establish population estimates to provide a basis for evaluation, relevant regional and national accounts, including Ballance (2006), Calbrade *et al*. (2010) and the citations of designated sites, have been used in conjunction with bird reports (Gibbs [ed], 2010).

Results from the intertidal surveys undertaken between Hinkley Point and Stert Point from April 2010 to January 2011 inclusive, indicate that the mudflats within the study area hold important numbers of waders and waterfowl, particularly the intertidal habitat between Stolford rock platform and Stert Point, with smaller numbers occurring between Hinkley Point (adjacent to the SSA) and Stolford. The rock platforms at Hinkley Point and Stolford are also important sites for loafing and roosting waterfowl, and the shingle beach, saltmarsh and adjoining mudflats between Stolford and Stert village are an important area for waders roosting at high tide.

4.1.1 Cited Species

A total of 16 species that appear as designated or cited features of the Severn Estuary SPA or Ramsar Site, or the Bridgwater Bay SSSI, were recorded in the study area. Of these, seven species appear as qualifying features of the Severn Estuary SPA (gadwall, shelduck, dunlin and redshank) or appear in the SPA Review (ringed plover, curlew and pintail). In addition, wigeon, teal, mallard, shoveler, tufted duck, grey plover, lapwing and whimbrel were recorded during the surveys and are listed in the waterfowl assemblage qualification for the SPA. Black-tailed godwit, which appears as cited interest for the Bridgwater Bay SSSI was also recorded.

[7] The South-west Biodiversity Implementation Plan, which is available through the website (http://www.biodiversitysouthwest.org.uk) covers the south-west region and includes Somerset (as well as Devon, Dorset, Gloucestershire, Wiltshire, Cornwall and the Isles of Scilly). As such there is ecological data available and targets have been set for this biogeographical region. It therefore seems sensible to include this as the region for the purposes of assessment.

Of the cited/qualifying species, gadwall, teal, shoveler, tufted duck and lapwing were recorded infrequently within the study area during the intertidal surveys, and generally in low numbers in terms of their respective Severn Estuary populations. Shelduck, pintail, grey plover, ringed plover, dunlin, whimbrel, black-tailed godwit and curlew were regularly recorded in numbers exceeding 1% of their respective Severn Estuary populations (or Bridgewater Bay population for black-tailed godwit). Wigeon, mallard and redshank were also recorded in numbers that exceed 1% of the Severn Estuary populations, although on a less frequent or occasional basis. For ease of description, the study area has been divided into the areas viewable from the four observation points (Count Sectors 1-4). The importance of each count sector to these species is discussed further below.

Shelduck

Numbers of shelduck that exceed 1% of the Severn Estuary SPA qualifying population were recorded on a regular basis in all count sectors throughout much of the year, but particularly from July to November, which covers much of the period when this species undergoes a moult of its feathers, and becomes temporarily flightless. The peak count of 2,049 shelduck represents 61.5% of the SPA population. In addition, counts that exceed the threshold of national importance for shelduck (782 birds, Calbrade *et al*., 2010) were recorded on 5-8 survey dates in each of the count sectors. To summarise, evidence from the surveys indicates that the intertidal habitat within the study area is likely to support a substantial proportion of the Severn Estuary population of shelduck during much of the year. The mudflats in the study area provide an important foraging resource to the Severn Estuary population of shelduck, and occasionally support numbers of national importance from July to November.

Wigeon

Numbers of wigeon that exceed 1% of the Severn Estuary population were recorded occasionally in Count Sectors 1-3 from November to January. The peak count of 312 wigeon represents 3.7% of the Severn Estuary population. Evidence from the surveys indicates that the mudflats in Count Sectors 1-3 (primarily between Hinkley Point and Wall Common) occasionally support numbers of wigeon that are important in terms of the Severn Estuary population during winter.

Mallard

Numbers of mallard that exceed 1% of the Severn Estuary population were recorded occasionally in Count Sectors 1 and 2, primarily from August to January. The peak count of 87 mallard represents 2.6% of the Severn Estuary population. Evidence from the surveys indicates that the mudflats in count sectors 1-2 (primarily between Hinkley Point and Stolford) occasionally support numbers of mallard that are important in terms of the Severn Estuary population during autumn and winter.

Pintail

Numbers of pintail that exceed 1% of the Severn Estuary Review population were recorded regularly in Count Sectors 1-3, from October to January. The peak count of 158 pintail represents 26.4% of the Severn Estuary Review population. Evidence from the surveys indicates that the mudflats in Count Sectors 1-3 (primarily between Hinkley Point and Wall Common) provide an important foraging resource to the Severn Estuary population of pintail during winter.

Ringed Plover

Numbers of ringed plover that exceed 1% of the Severn Estuary SPA Review population were recorded on a regular basis in Count Sector 2-4, during the spring passage period (April-May) and during part of the autumn passage period (in August). The peak count of 687 ringed plover exceeded the SPA Review population, and exceeded the national threshold of importance (330 birds, Calbrade *et al*., 2010). To summarise, evidence from the surveys indicates that the mudflats and rock platforms within the eastern half of the study area (primarily between Stolford and Stert Point) are likely to support a substantial proportion of the Severn Estuary population of ringed plover during the passage periods, providing high tide roost sites, and an important foraging resource.

Grey Plover

Numbers of grey plover that exceed 1% of the Severn Estuary population were recorded on a regular basis in Count Sectors 3 and 4, and occasionally in Count Sector 2, from October to January. The peak count of 975 grey plover is more than double the Severn Estuary population, derived from the 5-year peak mean WeBS counts for 2003/04 to 2008/09. This peak count also exceeded the national threshold of importance (530 birds, Calbrade *et al*., 2010). To summarise, evidence from the surveys indicates that the mudflats within the eastern half of the study area (primarily between Stolford and Stert Point) are likely to support a substantial proportion of the Severn Estuary population of grey plover during the winter, providing high tide roost sites, and an important foraging resource.

Dunlin

Numbers of dunlin which exceed 1% of the Severn Estuary SPA qualifying population of this species were recorded on a regular basis in Count Sectors 2-4 from October to January. The peak count of 12,590 dunlin represents 28.2% of the SPA population, and exceeds the threshold of national importance (5,600 birds, Calbrade *et al*., 2010). To summarise, evidence from the surveys indicates that the mudflats within the eastern half of the study area (primarily between Stolford and Stert Point) are likely to support a substantial proportion of the Severn Estuary population of dunlin during the winter, providing high tide roost sites, and an important foraging resource.

Black-tailed Godwit

Numbers of black-tailed godwit which exceed 1% of the Bridgewater Bay population of this species were recorded on a regular basis in Count Sector 4, and occasionally in Count Sectors 1-3, primarily from August to October (the autumn passage period). The peak count of 160 black-tailed godwits represents 70.8% of the Bridgewater Bay population. To summarise, evidence from the surveys indicates that the mudflats in the study area (particularly those adjacent to Stert village) are likely to support a substantial proportion of the Bridgwater Bay population of black-tailed godwit during the autumn passage period providing an important foraging resource.

Whimbrel

Numbers of whimbrel which exceed 1% of the Severn Estuary population of this species were recorded on a regular basis in Count Sectors 1-4 primarily from April to early June (the spring passage period) and to a lesser extent from Mid-July to Mid-September (the autumn passage period). The peak count of 254 whimbrel exceeds the Severn Estuary population derived from the 5-year peak mean WeBS counts for 2003/04 to 2008/09, and is likely to represent a substantial proportion of the national total (the maximum count of whimbrel in Great Britain in

2008, was 1,284 birds, in August, Calbrade *et al*., 2010). To summarise, evidence from the surveys indicates that the mudflats in the study area are likely to support a substantial proportion of the Severn Estuary population of whimbrel during the spring and autumn passage periods providing high tide roost sites and an important foraging resource.

Curlew

Numbers of curlew which exceed 1% of the Severn Estuary SPA Review population of this species were recorded on a regular basis in Count Sectors 2-4, particularly from July to January (the autumn passage and winter periods). The peak count of 739 curlew represents 18.9% of the SPA Review population. To summarise, evidence from the surveys indicates that the mudflats within the eastern half of the study area (primarily between Stolford and Stert Point) are likely to support a substantial proportion of the Severn Estuary population of curlew during autumn passage and winter, providing high tide roost sites, and an important foraging resource.

Redshank

Numbers of redshank which exceed 1% of the Severn Estuary SPA qualifying population of this species were recorded on a regular basis in Count Sector 4 (and occasionally in Count Sector 3), primarily from November to January. The peak count of 355 redshank represents 15.2% of the Severn Estuary population. To summarise, evidence from the surveys indicates that the mudflats within the eastern half of the study area (primarily between Wall Common and Stert Point) are likely to support a substantial proportion of the Severn Estuary population of redshank during winter, providing high tide roost sites, and an important foraging resource.

4.1.2 Non-cited Species

A wide range of species of waterfowl that do not appear as cited or designated features of the Severn Estuary SPA and Ramsar site or Bridgwater Bay SSSI were also recorded during the intertidal surveys, with most seen sporadically, or in relatively small numbers. However, little egret, oystercatcher, knot, bar-tailed godwit and turnstone were recorded regularly, in numbers that are potentially important in terms of their respective county (Somerset) populations. The importance of the study area to these species is discussed further below.

Little Egret

The peak counts of little egret on the Parrett Estuary in 2007 and 2008 were 62 (in July) and 31 birds (in June) respectively (Gibbs [ed] 2009, 2010). The monthly maximum counts of little egret reported in Somerset Birds 2007 and 2008 probably under-estimate the true population in the county, with many birds now occurring away from the main (well monitored) sites. However, even allowing for this, the numbers recorded in the study area between April and October 2010, will be of at least county importance. The intertidal habitat within the study area is likely to provide an important foraging resource for the county population of little egret.

Oystercatcher

Oystercatcher is described as a fairly common winter visitor and passage migrant in Somerset (Gibbs [ed], 2010). Large numbers of oystercatchers were recorded foraging and roosting on intertidal habitat within the study area throughout much of the survey period. The peak count of 506 oystercatchers recorded during the Entec surveys represents a substantial proportion of the peak monthly count of 571 birds recorded in Somerset in November 2008 (Gibbs [ed], 2010).

In view of this, the intertidal habitat within the study area (particularly in Count Sectors 1-3) is likely to provide an important foraging resource to the county population of oystercatcher.

Knot

Knot is described as a locally common winter visitor and passage migrant in Somerset (Gibbs [ed], 2010). The Parrett Estuary holds the vast majority of the Somerset population of knot, (all but 6 of the 4,036 knot recorded in Somerset in November 2008 were from the Parrett Estuary, Gibbs [ed], 2010). Large numbers of knot were recorded foraging and roosting on intertidal habitat within the study area (particularly between Stolford and Stert Point) during the Entec surveys from October 2010 to January 2011. The peak count of 3,575 knot recorded during the Entec surveys represents a substantial proportion of the county total, and exceeds the national threshold of importance for a site (2,800 birds, Calbrade *et al*., 2010). In view of this, the intertidal habitat within the study area (particularly in Count Sectors 2-4) is likely to provide an important foraging resource to the county population of knot, and occasionally hold nationally important numbers of this species.

Bar-tailed Godwit

Bar-tailed godwit is described as a scarce winter visitor and erratic passage migrant in Somerset (Gibbs [ed] 2010). The Parrett Estuary supports the bulk of the population where in 2008 a peak monthly count of 34 birds was recorded in Somerset in April (Gibbs [ed] 2010). The peak count of 175 birds recorded during the Entec surveys is likely to represent a substantial proportion of the county total, and on this basis, the intertidal habitat within the study area (particularly that within Count Sectors 2-4) is likely to provide an important foraging resource to the county population of bar-tailed godwit during the spring and autumn passage periods.

Turnstone

Turnstone is described as a locally common winter visitor and passage migrant in Somerset (Gibbs [ed] 2010). The Parrett Estuary supports the bulk of the county population where in 2008 a peak monthly count of 349 birds (of which 243 birds were on the Parrett Estuary) was recorded in Somerset in September (Gibbs [ed], 2010). The peak count of 95 birds recorded during the Entec surveys in April 2010 represents 27% of the September 2008 county total. Evidence from the 2010-11 intertidal surveys indicates that the intertidal habitat within the study area (particularly that within Count Sectors 2-4) is likely to provide an important foraging resource to the county population of turnstone during the spring and autumn passage periods and winter.

5. Conclusions

Evidence from the intertidal surveys undertaken between Hinkley Point and Stert Point between April 2010 and January 2011 inclusive, indicates that the mudflats and other intertidal habitat in this area (particularly that between Stolford and Stert Point, in the east of the study area) provides an important foraging resource to the Severn Estuary populations of shelduck, wigeon, mallard, pintail, ringed plover, grey plover, dunlin, whimbrel, curlew and redshank during the passage and /or winter periods. The intertidal areas also provide important high tide roost sites for these species, particularly on the rock platforms at Hinkley Point and Stolford, and on the shingle beaches, saltmarsh and adjoining mudflats along or above the high water mark. The intertidal habitat is also likely to support numbers of little egret, oystercatcher, knot, bar-tailed godwit and turnstone that are important in terms of the county (Somerset) population. The study area also occasionally supports nationally important numbers of shelduck, ringed plover, grey plover, knot, dunlin and whimbrel.

APPENDIX 20D: BADGER SURVEY RESULTS

POTENTIALLY EXCEPTED INFORMATION:

The information contained in this report is potentially excluded from disclosure under Regulation 12(5)(g) of the Environmental Information Regulations 2004 as such disclosure could adversely affect the protection of the environment to which the information relates.

APPENDIX 20E: HINKLEY BAT SURVEY REPORT

EDF Energy
Hinkley Bat Survey Report

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as ‘Hinkley C’) on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds.

This report details the work completed in respect to bats in 2009, comprising activity surveys, static Anabat monitoring and a building and tree assessment. It provides a description of the survey methodologies used and the results obtained. These results are used to draw conclusions regarding how the site is used for foraging, commuting and roosting. Relevant previous survey work for bats undertaken in 2007 and 2008 is also summarised.

1.2 Background Information

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. At the time of the bat surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1.1). The boundary of the SSA was therefore used to define the area for the 2009 bat surveys (which effectively updated and superseded the 2008 surveys). The SSA boundary includes all of the land within the final ‘Construction Boundary’.

1.2.2 Site Description

The majority of the land within the SSA is agricultural; comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small, rectangular broad-leaved woodlands are located within the northern part of the SSA and a square block of young broad-leaved plantation has been created in the central part of the area, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA. Two watercourses flow west to east through the SSA (further seasonal ditches also occur) and a further watercourse is present on its southern boundary. Three ponds occur within the SSA. In addition, there are three derelict stone barns.

The northern boundary of the SSA is adjacent to the Bristol Channel. A low cliff, between 0.2m and 10m in height, forms an escarpment between the land and sea.

The land immediately adjacent to the west of the SSA is similar in character to that within the western part of the SSA, i.e. it comprises agricultural fields (both arable and improved pasture), which are separated by intact species-poor and species-rich hedgerows. A small number of ponds occur and the upper reaches of the Bum Brook flow through the area.

The land east of the SSA is different in character to that within the SSA. It forms part of Bridgwater Bay SSSI and comprises large open fields separated by drains, with very few hedgerows present. The fields immediately adjacent to the SSA have been agriculturally improved and are relatively species-poor. However, those fields to the south and east are less intensively grazed, support a more varied sward and have a greater diversity of plant species.

The proposed development falls into the Vale of Taunton and Quantock Fringes Natural Area[1] (English Nature, 1998), which describes the lowland landscape around the major towns of Taunton, Wellington and Minehead between the Quantock Hills, Brendon Hills, Exmoor and the Blackdown Hills. The Natural Area is characterised by a wide variety of habitats and species, including hedgerow and hedgebanks, calcareous grassland, streams, woodland and scrub, nightingale, otter and bats, all of which occur or could occur within the site.

The Natural Area immediately to the east of the site is the Somerset Levels and Moors Natural Area (English Nature, 1997).

2. Methodology

2.1 Desk Study

Existing information regarding bats within the SSA and surrounding land was obtained from the following sources:

- EDF Energy (and British Energy, which became part of EDF Energy in 2009) which has conducted a wide range of ecological surveys of its land holding and employs a conservation warden at Hinkley to help manage its land and undertake biological recording;
- Somerset Environmental Records Centre (SERC), which also hold all the records from the Somerset Bat Group;
- The Environmental Statement (ES) for the Decommissioning of Hinkley A (Magnox, 2006);
- the ES and supporting information (including from the SEI) for the proposed West Hinkley Wind Farm (Dulas, 2006);

[1] The classification of areas of the country into distinct Natural Areas (NAs) was undertaken by English Nature (now Natural England) in order that areas of the countryside identified by unique combinations of physical attributes, wildlife, land use and culture could be grouped together. Overall, 143 NAs, including 24 Coastal NAs have been identified.

- communication with the Somerset Bat Group; and
- communication with the Bat Conservation Trust (Philip Briggs, National Bat Monitoring Programme Team Co-ordinator).

Data relating to bat sightings and roosts from SERC was requested in May 2009 (following an initial request in 2007) for 10km from the SSA boundary to ensure that any additional new records submitted in the intervening period were captured.

2.2 Field Surveys

The methodology for undertaking all the bat survey work followed that advised by Natural England (The Bat Mitigation Guidelines, English Nature, 2004) and Bat Conservation Trust Good Practice Survey Guidelines (2007). Sunset times for all the surveys were taken from Metcheck (www.metcheck.com).

2.2.1 Habitat Suitability

Habitat suitability for bats was considered during the extended Phase 1 habitat assessments in 2007, 2008 and 2009 (detailed in Entec report reference 19801cb304), whilst undertaking bat activity surveys (see below), the building and tree roost assessment and from aerial images of the site. This identified features that offer potential for:

- roosting e.g. trees, buildings, other built structures;
- commuting e.g. provided by structural features such as woodland edge); and
- foraging (e.g. over areas of grassland or adjacent to woodland).

Features that reduce the value of a feature or habitat for commuting or foraging were also noted. This element of work was used to help design activity survey transects and to determine locations for static monitoring points.

2.2.2 Buildings Assessment

Five buildings (Buildings 2, 3, 4, 5a and 5b) are located either within or immediately adjacent to the SSA. A further building (Building 1) is located approximately 220m to the west of the SSA boundary. Building 1 has been surveyed in relation to previous development proposals (e.g. the wind farm), but was screened out of detailed assessment due to the distance from the SSA. A small number of other buildings associated with the existing Power Station are present within the SSA boundary. These relatively new buildings offer very little roosting potential for bats and were screened out of the detailed assessment. The locations of Buildings 2-5b[2] is shown in Figure 2.1.

[2] Buildings 5a and 5b are adjacent to each other and have been shown on the figure as Building 5. Where this building is referenced as Building 5 within this document it refers to both buildings. Building 5a is the smaller building, whilst Building 5b is a larger derelict farm house.

Screening

Buildings 2-5b were inspected externally on the 15 June 2009 to determine their suitability for bat roosts and to decide on further survey requirements. Due to poor structural integrity of the buildings, and the associated health and safety risk, access was only available at this time into Building 3. Further inspection of Buildings 2, 4, 5a and 5b was completed on the 16 September 2009. All inspections were carried out by a Natural England licensed bat ecologist (Lynn Whitfield, NE licence no. 20084000 and Katheryn Leggat, licence no. 20093209). The methodology included:

- close inspection to determine whether the external surfaces provide roosting opportunities (e.g. gaps in stone wall) or the building provided opportunity for bats to access potential roost spaces (e.g. gaps or cracks in stone or mortar work, loose tiles, open windows and doors);
- search for bat droppings (e.g. in cobwebs or below potential roost access points); and
- description of structure (only brief if considered not suitable).

For Buildings 4, 5a and 5b, a pole-mounted camera was used to inspect the interiors and, although the resolution of the images was not high enough to search for details such as droppings, it did enable the general internal structure to be examined. Building 2 was not inspected internally with the camera as it was possible to see much of the inside through the numerous open doorways and windows using binoculars.

Detailed notes on all buildings were taken.

Emergence/Re-Entry Surveys

Following the screening survey it was determined that an emergence (dusk) and re-entry (dawn) survey was required for Buildings 2-5b[3]. Due to the relatively small size and simple shape of the buildings each survey required only two people, stationed at opposite corners. The emergence surveys started just prior to dusk and lasted between 1.5 and 2 hours. The re-entry surveys started 2 hours before dawn and finished at dawn. During each survey the buildings were watched for bats entering or exiting. Due to the derelict nature of the buildings, this focused primarily on open doors, windows and roofs. Bat calls were recorded using bat detectors (e.g. Batbox duet or Pettersson D-230) and recording devices (e.g. an Edirol R09), which were subsequently analysed using BatSound.

The dates of the surveys and weather conditions are provided in Table 2.1.

[3] Due to the close proximately of Buildings 5a and 5b, these were surveyed at the same time.

Table 2.1 Building Emergence/Re-entry Survey Dates and Weather Conditions

Building Number	Date	Emergence or Re-entry	Weather Conditions
2	02 June 2009	Emergence	Dry, calm and clear (0% cloud cover). Temp 23ºC - 15ºC.
4 and 5	15 June 2009	Emergence	Dry, light winds and clear (20% cloud cover). Temp 17ºC - 13ºC.
3	18 June 2009	Emergence	Dry, moderate winds and scattered cloud (60-90% cloud cover). Temp 17ºC - 15ºC.
2	10 July 2009	Re-entry	Very light drizzle, light wind and cloudy (95%). Temp 17ºC - 19ºC. RH 71% - 64%
4 and 5	31 July 2009	Re-entry	Dry, calm and clear (20% cloud cover). Temp 15ºC - 14ºC. RH 74% - 75%
3	04 August 2009	Re-entry	Very light drizzle, light wind and cloudy (100%). Temp 18ºCºC - 17ºC. RH 87% - 93%

Although the primary aim of the survey was to investigate roosting in the buildings, all bat activity at the time of the emergence and re entry surveys was recorded. Therefore, information collected on these dates has also been used to form a picture of bat activity across the SSA.

2.2.3 Tree Assessment for Roost Sites

There are nine woodland blocks within the SSA. The locations and references for these are shown in Figure 2.2.

Screening

An initial inspection of the semi-mature and mature trees (scrub or very young trees were screened out without assessment due to their very low potential to support bat roosts) within the woodlands in the SSA, specifically to identify potential for roosting bats, was completed on 16th and 18 March 2009. This is an appropriate time of year to complete this type of survey as there are no leaves on the trees, which if present could obscure features on the trunk and branches. The survey comprised:

- detailed inspection, using close focus binoculars to identify features that might offer roosting potential (e.g. including holes, cavities, splits, exfoliating bark and dense or woody ivy cover); and
- recording the location of the tree using GPS, and features of interest, if the tree offered potential for roosting bats.

Detailed notes were made and features with a medium to high potential to support bats were recorded.

Detailed Inspection

A detailed inspection of those trees supporting medium-high and high potential features (as identified during the screening survey) within woodlands A, C, D and G was completed on the

25 November 2009 by Greena Ecological Consultancy (GEC). A total of 22 trees supporting 47 features were subject to this inspection. Two features could not be assessed in detail as they could not be safely accessed. Dense ivy was not inspected as in most cases this cannot be fully assessed without removing the ivy, which could harm bats present and/or remove roosting sites.

Each feature was accessed using ladder and tree climbing techniques and then examined for evidence of use by bats (e.g. droppings or roosting individuals) using a combination of hand held bright torches (0.5-2M candle power), high power mini torches and a 90cm long 5mm diameter fiberoptic viewing probe. As a result of the detailed inspection, the potential for each feature to support bats was refined based on the following criteria:

- no potential - feature provides no potential to support bats because it is superficial;
- low potential - feature unlikely to be used by bats as it is too shallow, wet or light;
- medium potential - feature offers some suitable conditions for roosting and could possibly be used by small numbers of bats;
- high potential - feature offers ideal conditions for roosting e.g. deep cracks with stable temperatures and relatively dry; and
- confirmed - evidence of bat roosting found e.g. droppings.

Information about the trees surveyed was also recorded including approximate age, height, diameter, root/loss damage, fungal infection, dead sections, open/closed habitat location and soil type.

Emergence/Re-Entry Surveys

Following the screening survey it was determined that a number of trees within the woodlands had medium to high or high potential to support bat roosts and that emergence (dusk) and re-entry (dawn) surveys were required. Due to the number and locations of the trees highlighted (i.e. within several scrub woodlands) it was not practical to survey every tree individually. Instead, surveyors were stationed at strategic points at the edges of the woodlands, chosen on the basis of visual coverage (i.e. being to see a lot of the woodland edge) and likely commuting routes between the woodlands and the surrounding landscape (e.g. connecting hedgerows). The survey points for the re-entry survey were altered slightly in response to the results of the emergence survey. The locations of the survey points are shown in Figure 2.2.

The emergence surveys started around dusk and lasted between 1.5 and 2 hours. The re-entry surveys started 2 hours before dawn and finished at dawn. During each survey the woodlands were watched for bats entering or exiting. Bat calls were recorded using bat detectors (e.g. Batbox duet or Pettersson D-230) and recording devices (e.g. an Edirol R09), which were subsequently analysed using BatSound.

The dates of the surveys and weather conditions are provided in Table 2.2.

Table 2.2 Tree/Woodland Emergence/Re-Entry Survey Dates and Weather Conditions

Survey Points	Date	Emergence or Re-entry	Weather Conditions
1-5	23 June 2009	Emergence	Dry, light winds and clear (0% cloud cover). Temp 22ºC - 16ºC.
6-10	29 June 2009	Emergence	Dry, light winds and clear (5% cloud cover). Temp 18ºC - 18ºC.
1-5	29 July 2009	Re-entry	Dry, light winds and cloudy (95% cloud cover). Temp 17ºC - 15ºC.
6-10	11 August 2009	Re-entry	Dry, light winds and cloudy (80% cloud cover). Temp 21ºC - 17ºC. RH 75% - 83%

Although the primary aim of the survey was to investigate roosting within the woodlands, all bat activity was recorded. Therefore, information collected on these dates has also been used to form a picture of bat activity across the SSA.

2.2.4 Walked Activity Surveys

General Method

Surveys to sample the distribution of and usage by foraging and commuting bats in the SSA were completed in 2007, 2008 and 2009. The methodologies for each of the surveys are broadly similar, having followed guidance provided in the Bat Conservation Trust Good Survey Guidelines (2007).

In all years the bat activity has been sampled by following transect routes around various parts of the SSA (depending on access availability). During each survey the transect was walked at a steady pace and bat calls were recorded using bat detectors (e.g. Batbox duet, Pettersson D-230 or Anabat SD1) and recording devices (e.g. an Edirol R09), which were subsequently analysed using BatSound or Analook, depending on the method of recording. A number of indistinct calls were verified by Philip Briggs from the BCT.

During each activity survey, a note was made of the likely bat species, the location of the registration and other detail (where discernable) such as direction of flight, activity (e.g. foraging or commuting), number of passes and number of bats.

All surveys commenced around sunset and lasted between 2 and 3 hours to coincide with the time when bats are most active during the night, as this is widely recognised as an optimal time to survey for bat activity. At least one circuit of each transect was completed within this time on each survey visit.

Survey Locations

Each activity survey transect has followed a different route. This is in part due to the site boundary changes and associated access restrictions (section 1.2.1), which required part of the transect routes in 2007 to follow footpaths, but the transect routes have also varied with the aim of sampling as much of the site as possible and to vary the time different locations within the SSA were sampled. Figures 2.3a-2.3c illustrate the transect routes taken in 2007, 2008 and 2009 respectively. This figure shows that despite the varied transect routes, the entire site has been well sampled for bat activity. Note that on most of the survey dates (see below) two different transect routes were surveyed.

Timing

The survey dates and weather conditions of each transect completed are provided in Table 2.3. A total of 18 transect routes across the SSA has been completed between 2007 and 2009.

Table 2.3 Activity Survey Dates and Weather Conditions

Date	Number of Transects	Weather Conditions
2007		
26 May 2007	One	14ºC, 50% cloud cover, wind 4-5: light to moderate
23 July 2007	One	14ºC, light rain, wind 2-3: light. (NB Heavy rain during preceding 24 hours)
22 August 2007	One	15.5ºC, 10% cloud cover, wind 2-3 light wind
26 September 2007	One	10.5ºC, 60% cloud cover, wind 4-5: moderate with gusts
2008		
10 September 2008	Two	17.4ºC (start), 15.1ºC (end), 100% cloud cover, light drizzle at start of survey and very windy especially in exposed areas.
24 September 2008	Two	16.1ºC (start), 14.6ºC (end), 100% cloud cover, with a light breeze.
2009		
19 May 2009	Two	Dry, light winds and scattered cloud (10-50% cloud cover). Temp 16ºC - 14ºC.
18 June 2009	Two	Dry, moderate winds and scattered cloud (60-90% cloud cover). Temp 17ºC - 15ºC.
13 July 2009	Two	Dry, light winds and cloudy (80% cloud cover). Temp 23ºC - 18ºC. RH 58% - 73%. (heavy rain prior to survey)
17 August 2009	Two	Dry, calm and scattered cloud (50% cloud cover). Temp 24ºC - 20ºC. RH 57% - 68%
03 September 2009	Two	Dry, moderate winds and cloudy (60-100% cloud cover). Temp 18ºC - 15ºC.

Note that the results described in section 3.2.4 also take into account activity of bats recorded during the building and tree emergence/re-entry surveys.

2.2.5 Driven Activity Surveys

Two driven transects were undertaken in 2007 to sample bat activity within a 2km zone around the SSA. The transect routes are shown in Figure 2.3a. An Anabat detector was fixed to a car with the microphone pointing out of the rear passenger window. The speed of the driven transect was between 10mph and 20mph, with two-minute listening stops. An amber flashing beacon and warning sign on the car warned other drivers of the slow moving vehicle. This is a recognised method for sampling bat activity (Bat Conservation Trust, 2007) and allows a wide area to be covered (for contextual purposes) within the period of peak bat activity after dusk.

The dates the driven activity transect routes were completed and the weather conditions are provided in Table 2.4.

Table 2.4 Dusk Driven Transect Survey Dates and Weather Conditions

Date	Weather Conditions
18 July 2007	16.5ºC, clear conditions and a light southwest wind (3-4)
22 August 2007	16ºC, fine, dry conditions with a moderate northerly wind 4-5.

2.2.6 Static Bat Detectors (Anabat)

Two Anabat SD1s units were deployed as static recorders from June until September. The units were hidden at locations along prominent linear features such as hedgerows. The positions were regularly altered to sample different locations within the SSA (Figure 2.1). Each Anabat was set twice in each location (apart from location 5), with the memory cards and batteries changed prior to re-setting the unit the second time. This ensured that should the Anabat fail during either the first or second recording period at each location data would still be collected. The duration each Anabat sampled was dependant on the battery life. Hi-mics were used so that the microphones could be placed between 1m and 2m above the ground and sensitivity levels were maintained at around 5 to filter out disturbance, for example from rustling leaves, but to ensure fainter calls would triggered the unit to record. Table 2.5 shows when the units were deployed at each location.

Table 2.5 Anabat Locations, Deployment Dates and Rationale for Site Selection

Location Reference and Grid Reference	Dates	Number of Days Sampled in each Location	Reason for Location
Anabat A - always located on the ‘green lane’ in response to the Barbastelle records collected in 2007			
1 ST205 454	05/06/09 - 18/06/09	13	At this location there is a dense tall hedgerow on both sides of the track (‘green lane’) creating a dark and sheltered corridor.
2 ST201 453	18/06/09 - 01/07/09 and 10/07/09 - 20/07/09	23	Located at the junction of the ‘green lane’ with a dense north-south hedgerow that connects to woodlands to the north.
3 ST198 454	20/07/09 - 02/08/09	13	Located near the junction of the ‘green lane’ with a dense north-south hedgerow that connects to the valley to the south.

Table 2.5 (continued) Anabat Locations, Deployment Dates and Rationale for Site Selection

Location Reference and Grid Reference	Dates	Number of Days Sampled in each Location	Reason for Location
Anabat A - always located on the 'green lane' in response to the Barbastelle records collected in 2007			
4 ST207 454	14/08/09 - 31/08/09	17	Located to sample the eastern end of the 'green lane' to determine whether Barbastelle travel the entire length of this feature. At this location there is also a junction with a north-south hedgerow leading to further hedgerows to the south, east and west.
5 ST207 453	09/09/09 - 23/09/09	14	Located within a hedgerow immediately east of the access road. At the western end of the hedgerow sampled in Location 4.
Anabat B			
1 ST197 454	05/06/09 - 18/06/09	13	Located at the crossroads of Benhole Lane and the 'green lane' which are both tall mature and established landscape features.
2 ST197 456	18/06/09 - 01/07/09 and 10/07/09 - 20/07/09	23	Located on the northern part of Benhole Lane in a sheltered valley.
3 ST203 456	20/07/09 - 03/08/09	14	Located at the SW corner of Woodland C with the aim of sampling a dark corridor formed by the wood and adjacent hedgerow.
Anabat B			
4 ST209 454	14/08/09 - 31/08/09	17	Located at the juncture of hedgerows which could be used for commuting to the mosaic of habitats south of the existing Power Station.
5 ST207453	09/09/09 - 23/09/09	14	Located on a prominent hedgerow and ditch immediately west of the access road and opposite the location for Anabat A.

The Anabat recordings were analysed to identify the species present using Analook software. Due to the extremely large number of bat registrations recorded by both Anabats, the analysis has been restricted to identifying calls from key species, namely those listed under Annex II of the Habitat Regulations, which are Barbastelle, lesser horseshoe and greater horseshoe.

2.2.7 Survey Limitations

All the surveys (excluding the static Anabat monitoring) were completed in suitable weather conditions (as set out in EN, 2004). However in order to achieve this, one building and one tree re-entry survey were postponed by approximately one week to avoid heavy rain. This resulted in these surveys being completed in early August rather than in the optimum month of July. However, this delay is not considered to have significantly altered the conclusions resulting from these surveys, as the results achieved in August are consistent with all the other surveys completed.

Due to the derelict nature of the buildings, the surveys of these features were constrained on the basis of the health and safety risk, namely entry into all but one of the buildings was prohibited. This may have resulted in a lack of finer detail regarding depth and size of some features that could not be accessed to allow a detailed assessment using an endoscope. However, every building was subject to external and internal inspection and two surveys (one emergence and one re-entry). Therefore, it is considered that a reasonable and sufficient level of effort and assessment has been completed to determine the value of the buildings to roosting bats and it is unlikely internal inspection would alter the conclusions reached.

One of the inherent difficulties in using Anabat detectors is the balance between placing the microphone in a prominent place, so that bat calls are recorded, whilst also sheltering the microphone from wind and leaves (that will trigger the recording device) and ensuring the unit is hidden to avoid theft. For the majority of the survey period this was achieved. However, on very windy nights, and in certain static locations, interference increased and consequently the quality of the bat calls recorded was reduced. Equally, very high levels of cricket calls (which are at a similar frequency to bats) also affected the quality of the results on a small number of nights. It is considered unlikely that reduced quality of data on a limited number of nights would significantly affect the conclusions drawn, due to the large quantity of data collected.

3. Results

3.1 Desk Study

3.1.1 Desk Study Records

Regular bat surveys have not been undertaken by the BE Site Warden, although common species such as pipistrelle (species does not appear to have been determined[4]) and noctule are known to occur through *ad hoc* surveys using bat detectors (Burrell, 2006).

SERC records were analysed following the receipt of an updated search (for 10km around the SSA boundary) in May 2009. The more notable records in the immediate area around the SSA are as follows:

- There are four reports of grey long-eared bat listed between 1996 and 1998 all from grid reference ST207458 (near or in the plant training building);
- There is one record of lesser horseshoe bat. The species was recorded in flight at ST206 455 on 28 September 2006. This is within the SSA boundary close to the east-west green lane. The origin of this record is unknown;
- Brown long-eared bat, noctule and serotine are listed as being occasional, frequent and rare respectively at ST200456 between 28 June and 28 September 2006 (as

[4] These records may have been made before the split of the two commoner pipistrelle species (*Pipistrellus pipistrellus* and *Pipistrellus pygmaeus*)

part of survey work for the West Hinkley Wind Farm). This location is within the coastal part of the SSA boundary.

A 10km search for bat records was conducted to gain insight into bat activity in the wider area, particularly roost locations and records of nationally rare species/those with a restricted range known to occur in Somerset. The most notable results were as follows:

- There are no known barbastelle roosts and no records of the species within 10km of the SSA boundary;
- There are five lesser horseshoe bat roosts (both summer and hibernation) between 7.5km and 10.2km of the SSA. These roosts are all in the Quantock Hills;
- The furthest of these lesser horseshoe bat roosts from the site (10.2km south south-east) also supports greater horseshoe bat;
- The closest brown long-eared bat roost is approximately 2.8km to the south-east of the SSA at ST237 428. There are two further roosts between 8 and 10km of the SSA.

Additional information was sought from Mr Edward Wells (Somerset Bat Group) with regard to the records of grey long-eared bat, as SERC were unable to obtain further details with regard to authenticity or origin. Mr Wells has stated that in his opinion there is one confirmed record of a grey long-eared bat from Hinkley. This animal was found in the administration block of the operational plant and taken into care. All relevant biometrics were taken to confirm a positive identification of the species, and the bat was released in the same area.

3.1.2 Previous Survey Information

Bat surveys were conducted for West Hinkley Wind Farm (WHWF) during 2005 and 2006 (Dulas Ltd, 2006). Roost surveys were undertaken of 3 of the 4 buildings and all suitable mature trees within the SSA boundary, and transect surveys were completed to record bat activity within the site.

Bat droppings (no species specified) were found in one of the four buildings surveyed in 2005 but no evidence of bats was found during repeat surveys in 2006. The ES concluded that none of the buildings were used as maternity roosts, but that small numbers of bats could use the buildings occasionally for shelter or hibernation. Limited numbers of mature trees were found to be present within the WHWF survey area. No tree roosts were found. A number of transect routes were walked on several occasions during 2006 (between the 28 June and 03 August). The presence of the following species was recorded: common and soprano pipistrelle, noctule, serotine and bat species in the genus *Myotis*. Common pipistrelle was the commonest species and was recorded on all survey dates. Bat activity appears to have been spread throughout the WHWF survey area with most of the records concentrated along the hedgerows, woodland edges and along the coastal strip.

Supplementary post-submission information for the wind farm application was collected in April and May 2007 by Michael Woods Associates, to a survey protocol agreed with West Somerset Council. This involved two April and two May survey visits, during which three surveyors walked separate transects, all of which overlapped the SSA boundary, and one of which was entirely within it (the entire east-west green lane was covered during each survey). Each survey resulted in 10.5 hours of data being collected from areas within and adjacent to the

SSA boundary. The buildings on site were also visited and assessed for their potential to support roosting bats. Static Anabats were deployed at three locations within the SSA to collect complementary data.

These 2007 surveys concluded that the coastal fields had relatively little bat activity and that there was no evidence of roosting within the buildings. Five bat species were recorded during the work: common and soprano pipistrelle, noctule, lesser horseshoe bat and at least one *Myotis* species. *Pipistrelle* sp. bats were recorded on all surveys, with other bat species being far less frequent (only a small number of records and not recorded during all surveys)[5]. The report identified that several localised sections of hedgerow, including two along the east-west green lane appeared to be of local importance to bats.

Barbastelle is listed in the Vale of Taunton and Quantocks Fringes Natural Area Profile (English Nature, 1998) as a species that has been recorded several times in recent years. This Natural Area occupies the low ground between the Quantock Hills, the Brendon Hills and Exmoor and the Blackdown Hills and extends east of the Quantocks to meet the Somerset Levels. It is bordered to the north by the Bristol Channel Coast. As such, it encompasses the SSA.

A breeding colony of Barbastelle is known to occur at Horner Woods, near Minehead, approximately 30km to the west of the SSA. These bats have been reasonably well studied and in a study in 2000 (Natural England, 2009), they travelled up to 10km from the roosts (which changed regularly) and used a total area of $180km^2$. The BCT also provided a bat detector (not roost) record of Barbastelle from Combe Sydenham, approximately 14km south-west of the SSA. Barbastelle have also been recorded around Old Cleeve, approximately 16km to the west of the SSA (Geoff Billington, *Pers comm*.).

3.2 Field Study

3.2.1 Habitat Suitability

The most suitable areas of bat habitat provide good roosting locations, an abundance of prey items and well connected links between the roosts and foraging sites, as demonstrated by the features identified as being of high value to bats within Bat Surveys - Good Practice Guidelines (BCT, 2007) are:

- buildings, trees or other structures with features of particular significance for roosting bats;
- habitat of high quality for foraging bats e.g. broad-leaved woodland, tree-lined watercourses and grazed parkland; and
- site connected to the wider landscape by strong linear features that would be used by commuting bats e.g. river/stream valleys or hedgerows.

[5] There were two records of lesser horseshoe bat: one on 04 April 2007 and one on 18 May 2007. One of the encounters was on the east-west green lane with the other near the footpath west of Pixies Mound field.

Roosting Opportunities
Within the SSA there are four buildings (excluding those buildings associated with the Power Station). These are all built from stone and are considered to provide relatively limited roosting opportunities due to their derelict condition (see section 3.2.2 for more detail). There are few mature trees within the SSA and only a small number are likely to offer features suitable for roosting bats (see section 3.2.3). There are no other features within the SSA that could be used by roosting bats (e.g. mines or caves). Therefore, the SSA provides limited opportunities for roosting bats and is unlikely to support any large hibernation or maternity roosts.

Foraging Opportunities
A mixture of habitats occurs within and adjacent to the SSA, ranging from large arable fields to broad-leaved woodland and mosaics of scrub and grassland. The large arable fields are unlikely to provide good foraging habitat as the crop monocultures will support few invertebrates. The woodlands, hedgerows and areas of scrub are likely to support a wider range of invertebrates and therefore are relatively more valuable foraging locations. The water features within the site comprise minor watercourses and small ponds, which are unlikely to be large enough to support sustained productive foraging locations, but which do provide a diversity of invertebrates within the SSA. Therefore, it is considered the SSA contains pockets of suitable foraging habitat for bats, but much of the SSA is largely unsuitable.

Commuting Opportunities
As indicated above, the watercourses that are present within the SSA are minor and are poorly connected to the wider landscape. In many locations they also do not have adjacent hedgerows or tree-lines that would shelter commuting bats (particularly those species that do not readily fly away from cover). However, all the fields are bounded by hedgerows, which although managed, are mature and dense and are likely to form strong landscape features. Further, the hedgerow network within the SSA is well connected to hedgerows present within fields to the west and south. The hedgerows will also shelter commuting bats from the prevailing winds. Therefore, it is considered the SSA provides good connectivity for commuting bats, both within the SSA and into the wider landscape.

Overall Suitability
It is clear that the habitats within the SSA provide a varying degree of suitable habitats for bats. Therefore, it is concluded that overall, the habitats within the SSA are of moderate value to bats.

3.2.2 Building Assessment

Screening Surveys (Internal and External)

Building 2
Building 2 is a tall two-storey building with an approximate footprint of 10m x 20m, with thick stone walls and a pitched roof made from corrugated material (likely asbestos). In the past, this building was a farmhouse. Internally, the original structure would have supported two levels, although the floor has now largely collapsed with the upper floor being open to the rafters (i.e. no separate roof void). Large sections of the walls are missing, with one long side almost completely open.

As the interior of this building is exposed to the elements it is unlikely to support a maternity roost because bats require a dry, warm, stable and sheltered space for this type of roost.

However, cracks and crevices between the stones may lead to substantial spaces within the walls, and may provide both hibernation and cool summer roosts for a low number of crevice-roosting species.

Building 3

Building 3 is a small, open-fronted stone barn with a fairly new sloping roof constructed of corrugated asbestos. Due to its construction, the interior of the building is exposed and unlikely to create a stable or warm environment for roosting. However, the building is likely to remain largely dry and the thickness of the walls may create more stable conditions inside the wall. Therefore, the crevices in the stonework of the walls, both internally and externally, have the potential to lead to cavities within the wall, which could support roosting bats. Most of these cavities could be examined and were full of cobwebs. The exception to this was a crevice in the internal back wall, close to the west wall and about 1.8m from the floor, which was free of cobwebs. Two bat droppings were found on a ledge a few centimetres below this crevice which would suggest that it is used as a roost site and, from the size and shape of the droppings, by a pipistrelle species. Hay bales were stacked against most of the back wall at the time of survey, which could conceal further suitable crevices. Given the likely environmental conditions provided by the building, it is unlikely to support a maternity roost.

Building 4

Building 4 is a single-storey barn with an approximate footprint of 13m x 7m. The barn has a double hipped[6] roof structure with wooden trusses and pegged beams, in an 'A' frame design supporting a pitched, clay tiled roof over stone walls. Internally, the ground is open to the rafters, hence no roof void is present, and the tiles are laid directly onto battens with no lining. There may be gaps between the beams and rafters of this traditional roof structure, which could offer roosting opportunities, as do gaps under the barge boards on the exterior of the barn.

Generally the barn is in a good state of repair. However, the walls do support at least 25 gaps between stones and there are openings around the lintel and wooden beams which frame the door. These gaps could lead to cavities inside the walls. Although the roof is largely in place, several tiles are missing which is likely to render the roof space draughty. As such, although the cracks and crevices which this building supports may provide summer and winter roosts for a low number of crevice-roosting bat species the building is unlikely to be warm enough or provide stable environmental conditions for a maternity roost.

Building 5a [Smaller of buildings at site 5]

Building 5 is single-storey building with a footprint of approximately 10m x 6m. It has thick stone walls on three sides and is open along its east facing aspect. The pitched roof is supported by trusses of king post construction[7] and is tiled. Tiles are laid directly onto wooden battens with no lining. Between 7 and 8 tiles are missing but the roof is otherwise in comparatively good condition. In the stonework, there are over 40 gaps, all of which may provide access to cavities inside the walls. Cracks and crevices may provide summer or winter roosts for a low number of crevice dwelling bat species, but the building is unlikely to be warm or dry enough to

[6] The hip is the term given to the inclined line formed where two sloping roof surfaces turn an outside corner of a building. 'Double hipped' refers to a roof with two hips.

[7] King post truss has wooden trusses on a central vertical post.

provide a stable environment for a maternity roost. There are some wooden beams against the inside of the stone gable ends, the gaps behind which may also support roosting bats. The southern side of the structure (external) is completely overgrown and therefore not visible.

Building 5b
Building 5b is a single-storey barn with a footprint of approximately 15m x10m. It has thick stone walls which support a wooden 'A' frame roof, which is tiled. Tiles are laid directly onto battens, with no lining, and no roof void is present. The roof is in a poor state of repair, half of it having collapsed, which means that the inside of the building is very open and exposed, reducing favourability to bats. However, in the remaining section of roof there are 4-5 gaps in joints between beams and the walls support large, apparently deep gaps, around the window and door frames, which could offer potential roost opportunities. Dense ivy covers the north east corner of the barn and may conceal further crevices. Again, cracks and crevices may provide summer roosts for a low number of bats, but the building is probably not warm or dry enough to provide a stable environment for a maternity roost. The walls may provide an important hibernation resource for bats.

All Buildings
As the barns are in close proximity to habitats which offer foraging potential, and because they are connected to these features by hedgerows and ditches, Buildings 2, 4, 5a and 5b could be used by bats as night roosts/feeding perches; the latter would be indicated by collections of bat droppings or insect wings (prey remains) on the floor. Such evidence would not have been visible during the internal inspection using a remote camera as it did not give sufficient detail to distinguish this form of evidence from other debris on the ground. Although Building 3 offers similar potential for feeding perches it was inspected and no evidence was found to support this.

Emergence/Re-Entry Surveys

Building 2
During the emergence survey in June 2009, the first bat recorded (21 minutes after sunset) was a soprano pipistrelle, which appeared to emerge from the apex of the north-west corner of the building and then fly into the building through an open doorway on the north side. A limited number of further bats were seen on the north and west sides of the building (which are the most exposed) restricted to two common pipistrelle and one further soprano pipistrelle. Activity was much higher around the south and east sides of the buildings (which are nearer to hedgerows and are more sheltered). A common pipistrelle was observed 31 minutes after sunset repeatedly flying in and out of the building through a large south facing doorway. During the remainder of the survey common pipistrelle bats were seen on six occasions to enter or exit the building through the open east facing window.

The re-entry survey recorded a moderate number of common pipistrelle bats, although most appeared to be commuting and foraging along the nearby hedgerows. A single common pipistrelle appeared to enter the building through the east facing window from the north 41 minutes prior to sunrise, with another common pipistrelle appearing to the enter the building through the south facing doorway 32 minutes before sunrise.

Building 3
No bats were observed either leaving or entering Building 3 during the emergence and re-entry surveys. During the June visit the first bats observed were commuting common pipistrelle and

were recorded 30 minutes after sunset. Similarly, the last common pipistrelle heard during the re-entry survey was approximately 30 minutes before sunrise, suggesting this bat was not roosting in Building 3.

The building was filled with bales of hay for the majority of the survey period. However, during the re-entry survey at the beginning of August, when there was light rain and the building was empty, at least one *Myotis* sp bat was recorded circling and foraging within the barn for most of the survey period. This indicates the building may occasionally used for shelter and foraging by *Myotis* sp.

Building 4
A single common pipistrelle was observed leaving the building through a north facing doorway approximately 37 minutes after sunset during the emergence survey in June. A single common pipistrelle was also observed during the re-entry survey in July foraging around the building, then flying in and out of the south facing doorway a number of times before finally entering the building approximately 22 minutes before sunrise. No other bats were seen to enter or exit the building, although a reasonable number of common pipistrelle was recorded commuting and foraging in this location.

Building 5
No bats were observed entering or exiting the building during the surveys. Limited bat activity was recorded during the emergence survey in June, restricted to commuting common pipistrelle, noctule and serotine.

More bat registrations were recorded during the re-entry survey, including a *Myotis* sp. flying around the building and along the wall connecting the building to a hedgerow to the north over 90 minutes before sunrise. The last bat recorded during the re-entry survey was a common pipistrelle clearly commuting west to east around the building approximately 42 minutes before sunrise.

3.2.3 Tree Assessment for Roost Sites

Screening Surveys (Internal and External)
A total of 175 trees were assessed for their potential to support bat roosts. Of these, 43 trees (25%) were identified as having medium–high or high potential to support a bat roost due to the features present. Features that were considered to increase the likelihood of a roost a occurring (and therefore warrant a medium-high or high assessment) included woodpecker holes, rot holes, large cracks in limbs, dense ivy and flaking bark. Most of the tree species identified as having high potential are ash, pedunculate oak and field maple. No evidence of bats was found during the external screening surveys.

It was determined that further (internal) assessment of trees would concentrate on those identified as having medium-high or high potential, excluding those within Woodlands H and I (which will not be significantly affected by the development). Therefore, an initial 19 trees were subject to internal inspection. A further three trees were re-classified during the scoping visit prior to the internal inspection, such that a total of 22 trees were assessed internally.

A single confirmed bat roost was recorded during the internal inspection of the features surveyed. The feature supporting the roost is located within a field maple tree at the eastern edge of Woodland C and comprises a 25cm deep cavity approximately 7m above the ground.

Within the cavity a small number of bat droppings were found. Due to their location the droppings could not be accessed and were identified using the probe as either *Myotis* sp or Barbastelle.

Of the remaining trees, 11 are considered to have features with high potential to support a bat roost, with 17 high potential features identified in total, and three trees support features considered to have medium potential to support roosts. The high potential features comprise rot and woodpecker holes, dense mat ivy, flaking bark and rotten branches.

Woodland A supports one tree with a high potential tree, Woodlands C and D support three trees each with high potential features and Woodland G has four trees with high potential features.

Emergence/Re-Entry Surveys

Bats were only observed entering or exiting the woodlands on one occasion. This was during the emergence survey at position 4 (south of Woodland D) when two common pipistrelles were seen separately to leave the woodland and fly south then east, approximately 65 minutes after sunset. No bats were seen entering or exiting the woodlands on any other occasion.

The woodlands are well connected to the wider landscape via a network of hedgerows and many of the survey points recorded a moderate level commuting and foraging behaviour from a wide range of species.

3.2.4 Activity Surveys

Strategic Siting Area

Seven species of bat (or group of species in the case of *Myotis*) have been recorded during the activity surveys completed during 2007, 2008 and 2009 within the SSA. These are:

- Common pipistrelle;
- Soprano pipistrelle;
- Noctule;
- Serotine;
- Long-eared (likely to be brown long-eared);
- *Myotis* sp.; and
- Barbastelle.

It is not possible to separate the *Myotis* species based on the calls recorded. However, the characteristics of a number of very clear calls suggest that both Natterer's and Daubenton's are probably present.

Bats have been recorded throughout the SSA (Figure 3.1), although fewer bats were recorded in the southern part of the SSA, probably due to the poorer habitat (large arable fields dominate this area). Both Benhole Lane and the 'green lane' through the centre of the site appear to be well used commuting and foraging corridors. The enclosed footpaths around Woodlands C, D and G are also well used, as are the hedgerow south of Building 5 and the northern watercourse.

Common Pipistrelle

Common pipistrelle was the most frequently encountered bat species, has been shown to occur throughout the SSA and was recorded at least once on every survey visit. The earliest a common pipistrelle was observed was during the June activity survey, when a bat was recorded 24 minutes after sunset along the southern part of Benhole Lane (although an earlier bat was recorded exiting Building 2). During a number of the other surveys the first common pipistrelle heard was also in the western part of the site and often near to Benhole Lane. It has been shown that a small number of bats appear to be roosting in the buildings surveyed and this is reflected by the times common pipistrelle have been recorded prior to sunrise, many of which are within 60 minutes of sunrise.

Soprano Pipistrelle

One soprano pipistrelle was recorded in the SSA in 2007 (around the sewage treatment works in the eastern part of the SSA) and none in 2008.

In 2009, soprano pipistrelle was recorded at 20 locations, scattered fairly evenly throughout the SSA. This species was also recorded in every month between May and September, with a slightly greater number of registrations in June and July. Soprano pipistrelle bats were recorded 29 minutes after sunset on two occasions. The first was during the August activity survey adjacent to the Bum brook along the southern boundary of the SSA and the second was along the footpath east of Woodland D.

Noctule

In 2007, three registrations of noctule were recorded; two near the existing Power Station access road and one along the boundary of the SSA with Wick Moor.

Noctule bats were recorded in 23 locations during the 2009 surveys, concentrated around the woodlands in the centre of the SSA and the existing access road. The earliest a noctule was recorded within the SSA was during the July activity survey 35 minutes after sunset along the southern part of Benhole Lane. This is one of a small number of the registrations from Benhole Lane, with bats also recorded in the valley in the centre of the SSA and along the coast. Most of the remaining records are likely to comprise several passes of the same bat due to the timing of the calls. A noctule was also recorded 24 minutes prior to sunrise near Building 3 in July.

During the July visits up to two noctule bats were recorded foraging around the lights along the access road. The locations of the records also indicate that the hedgerow network around the woodlands is well used.

Serotine

One serotine was recorded along the SSA boundary with Wick Moor in 2007 (actually during the driving transect). None were recorded in 2008.

In 2009, serotine bats were recorded in 21 locations, all in the central and northern parts of the SSA. Serotine bats were particularly well recorded during the static surveys in June and July (i.e. for the buildings and woodlands) when many registrations (over 16 in one location) were recorded around all the woodland blocks. On one occasion in June, two bats were recorded foraging together along the south edge of Woodland C. All the serotine bats encountered during the surveys were recorded over an hour after sunset, with the earliest 61 minutes after sunset adjacent to Woodland C.

Long-Eared
In 2007, two long-eared bats were observed foraging along the ‘green lane’ during the June transect visit. No long-eared bats were recorded in 2008 and long-eared were only recorded in four locations during the 2009 surveys.

Three of the registrations are from the same static survey visit in June, where is appears a single bat may have travelled west to east across the SSA via the dense hedgerows connecting the woodlands. A further long-eared was recorded in July near to the existing Power Station gates.

Long-eared bats produce very quite calls and are therefore difficult to record using bat detectors. It is therefore likely that the distribution and abundance of long-eared bats across the SSA is wider and higher (respectively) than is indicated by the surveys.

Myotis sp.
Myotis sp. was recorded in four locations during the 2007 surveys and once during 2008. All the records are from the central part of the SSA. One of the 2007 records is around the sewage treatment works in the eastern part of the SSA. This is also where a Daubenton bat was recorded.

In 2009, *Myotis* sp. bats were recorded in 29 locations within the SSA. The locations of the registrations are spread throughout the site, although a slight concentration of calls occurs along the western SSA boundary. *Myotis* sp. were generally recorded at least an hour after sunset apart from the August activity survey when a *Myotis* sp. (probably a Daubenton’s[8]) was recorded 34 minutes after sunset by the ford on Benhole Lane adjacent to the south-west corner of the SSA.

Myotis sp. bat were frequently recorded foraging, particularly in association with buildings during the dawn surveys (e.g. Building 3 and 5). The latest a *Myotis* sp. bat was recorded within the SSA was 47 minutes before sunrise near to Building 4.

Barbastelle
Two Barbastelle bats were recorded during the 2007 July survey in the centre of the ‘green lane’ in the centre of the SSA. None were recorded in 2008.

Barbastelle were recorded in seven locations during the 2009 surveys, the details of which are set out in Table 3.1.

[8] This is based on the sound analysis and the location of the call, as Daubenton bats are frequently recorded foraging over water

Table 3.1 Records of Barbastelle (excluding Anabat Records)

Date	Time after Sunset (mins)	Time before Sunrise (mins)	Location	Number of Registrations/Activity
19 May 2009	108	-	East edge of Woodland F	1 pass
13 July 2009	72	-	Benhole Lane, near Building 3	1 pass
13 July 2009	103	-	Along ‘green lane’ - a section that has tall elms on the south side.	15 passes over 15 minute duration (not constant, three phases of activity). Probably foraging due to the pattern of activity but no feeding buzzes recorded.
29 July 2009	-	66	Adjacent to western edge of Woodland B of possible within woodland	1 pass
11 August 2009	-	69 (last call)	Eastern edge of Woodland E and B	Approximately 41 passes over 38 minutes. Probably foraging due to the pattern of activity but no feeding buzzes recorded.
17 August 2009	124	-	Along tall hedgerow in valley	2 passes
03 September 2009	86	-	Northern section of Benhole Lane	11 passes over 5 minute duration. Probably foraging due to the pattern of activity but no feeding buzzes recorded.

The records collected during the activity and emergence/re-entry surveys are concentrated in the western part of the SSA, primarily along the ‘green lane’, Benhole Lane and Woodlands B, E and F. On a number of occasions, data collected also suggest that barbastelle use the SSA for foraging (as well as commuting), as shown by the repeated passes, particularly on the 11 August 2009.

Wider Area

Driven transects in the area around the SSA recorded seven species of bat (or species group in the case of *Myotis* sp.). These were:

- Barbastelle;
- Long-eared;
- Serotine;
- Noctule;
- *Myotis* sp.;
- Common pipistrelle; and
- Soprano pipistrelle.

With the exception of common pipistrelle, the majority of bat activity recorded along the driven transect was concentrated in discrete areas. The greatest diversity of species was recorded in locations where there were areas of semi-natural habitats, such as woodland copses and open water. Bats were also recorded around the villages of Stogursey, Shurton and Knighton.

Five species of bat, including barbastelle, were recorded at Cross Elms Copse, to the west of the SSA. Hedgerows connect this copse to a number of small woodlands and plantations, including Horibere Woods, Martin's Wood and Great Plantation.

Serotine and noctule bats were recorded around the village of Wick, Upper Cock Farm, Brown's Cottage (to the east of Hinkley Point power station) and close to the power station on Wick Moor Drove. However, the level of bat activity in this area was generally lower than in areas to the west.

3.2.5 Static Bat Detectors (Anabat)

Both units recorded extremely large numbers of bat calls, particularly unit A (along the 'green lane'). Although not currently analysed in detail, some general conclusions drawn during the analysis are:

- Common pipistrelle is the most frequently recorded species. Although this may in part be due to their foraging habit of moving along features many times, it is considered likely this is a good reflection of common pipistrelle abundance within the SSA;
- Long-eared bat was recorded much more frequently than during the other bat surveys.

Barbastelle

Anabat A

Barbastelles were recorded on a total of 27 nights during the monitoring period (33% of the time). They were recorded at all the locations the Anabat was positioned along the 'green lane' and by the access road, although most registrations were at locations 2 (where a north-south hedgerow meets the 'green lane' from Building 5) and 4 (at the eastern end of the 'green lane'). The time that barbastelle were recorded by the Anabats varies considerably. The earliest recorded registration was 64 minutes after sunset on the 16 July, where-as the latest time barbastelle were recorded within the SSA was 122 minutes before sunrise on the 24 August. A summary of the records is provided in Table 3.2.

Table 3.2 Records of Barbastelle (Anabat A)

Anabat B

Barbastelles were recorded by Anabat B on 14 nights during the monitoring period (17% of the time) and were recorded from all five static positions, confirming use of Benhole Lane by this species. The results also show that barbastelle occur around Woodland C and also the southern edge of the SSA boundary, to the south of Pixies Mound. The earliest registration was 71 minutes after sunset on the 16 June, whilst the latest was 132 minutes before sunrise on the 27 July. A summary of the records is provided in Table 3.3.

Table 3.3 Records of Barbastelle (Anabat B)

Location	Date	Time after Sunset (mins)	Time before Sunrise (mins)	Number of Registrations
1	13/06/2009	109	-	3
	16/06/2009	71	-	1

Lesser Horseshoe

Five lesser horseshoe calls were recorded on the Anabats during the survey (7% of the nights sampled). These were all recorded on Anabat A, located at various positions along the 'green lane'. Each registration occurred on a different day, although in late August a lesser horseshoe was recorded on three days out of four. The earliest a lesser horseshoe was recorded was 80 minutes after sunset. A summary of the records is provided in Table 3.4.

Table 3.4 Records of Lesser Horseshoe

Location (Anabat A)	Date	Time after Sunset (mins)	Number of Registrations
2	11/07/2009	154	1
3	22/07/2009	80	1
4	21/08/2009	96	1
	22/08/2009	89	1
	24/08/2009	257	1

Greater Horseshoe
Four greater horseshoe calls were recorded on the Anabats during the survey (5% of the nights sampled). These were all recorded on Anabat A, located at various locations along the ‘green lane’ and adjacent to the access road. A summary of the records is provided in Table 3.5.

Table 3.5 Records of Greater Horseshoe

	14/07/2009	03.28	1
5	14/09/2009	01.54	1

4. Conclusions

4.1 Species Assemblage

Following extensive survey of the SSA it has been shown that the following species occur:

- Common pipistrelle;
- Soprano pipistrelle;
- Noctule;
- Serotine;
- Long-eared (likely to be brown long-eared);
- *Myotis* sp (likely to be at least Natterer’s and Daubenton’s);
- Barbastelle;
- Lesser horseshoe; and
- Greater horseshoe.

4.2 Roosting

4.2.1 Buildings

The four buildings assessed within and adjacent to the SSA are all very similar in construction and current condition. Hence, they all offer comparable potential roosting opportunities.

Due to the derelict condition of the buildings and their fairly exposed locations along the coast, they are all considered to have low potential for and are unlikely to support large maternity colonies of any species. However, there are cracks within the stone-work of every building that could be used for roosting by a small number of non-breeding bats (such as males or pre-pubescent females) and the surveys have shown that three of the four buildings do support very small pipistrelle roosts (likely to comprise one or two bats only). Despite the lack of evidence of roosting bats in either Building 5a or 5b, it is considered highly likely that these buildings will also be used by small numbers of roosting bats due to its similarity to the other buildings. The surveys indicated that only pipistrelle sp. bat was roosting in the buildings, however, there is also potential for *Myotis* sp. and long-eared bats to use them.

The cracks identified in the stone-work of the buildings could also lead to cavities within the walls, which could be sufficiently insulated (due to the thickness) to allow hibernation. It is considered unlikely that a large hibernation roost would occur, but small numbers of pipistrelle sp., *Myotis* sp. and long-eared bats could use the buildings during the winter, particularly if suitable hibernation sites are infrequent in the surrounding area.

4.2.2 Trees

Of the 74 trees assessed (excluding the trees in Woodland H and I), 22 trees (30%) have been identified as having medium-high and high potential to support bat roosts.

Of these, one tree has been found to support a confirmed bat roost. Due to the speed with which evidence of bat presence can degrade in the damp conditions within crevices, it is likely this feature had been used during 2009. The species of bat using this roost could not be determined, but is likely to be either *Myotis* sp. or barbastelle due to the size of the droppings found. However, based on the limited extent of the crevice it is highly unlikely to support a maternity roost of either of these species. Instead, the feature is likely to support an occasional low status roost only, used by individual or small numbers of bats. The feature could be used at any time of the year, including the winter, but only during milder periods of weather.

A further 11 trees also support features with high potential to support bat roosts and three trees support features with medium potential. Again, due to the decomposition of evidence of bat presence, it is possible these features have been used by bats previously. Further it is considered that these features could be used by bats throughout the year, except it very cold weather (e.g. $<5^{o}C$).

4.3 Activity (Foraging and Commuting)

The majority of the bat activity recorded during the surveys occurred in the sheltered parts of the SSA such as Benhole Lane, the woodland edges, along hedgerows and through the valley in the centre of the SSA. This can probably be attributed to general bat behaviour (using features for shelter and to avoid predators) in combination with the character of the landscape, which is exposed and largely influenced by intensive farming practices. The SSA is also adjacent to the Severn Estuary in a fairly exposed location, and is therefore prone to frequent windy conditions. This is likely to influence the number and distribution of aerial insect prey, as lower numbers of insects are found in more exposed areas[9].

Both commuting and foraging behaviour was recorded within the SSA. For example, many of the bat records comprise only a single brief pass, which indicates commuting behaviour. Every species recorded within the SSA exhibited this behaviour and this suggests that the extensive hedgerow network through the site is used by bats travelling between roosts and foraging locations. Feeding buzzes from both pipistrelle and *Myotis* species were also recorded and foraging can be inferred from the behaviour seen relating to noctule, serotine and barbastelle (i.e. a number of passes in quick succession along a feature).

The number of registrations and the location of these throughout the survey area indicate that all of the species recorded, apart from the horseshoe and long-eared bats, occur frequently throughout the SSA. Further, it is considered likely that the long-eared bats have been under-recorded (due to their quiet call) and are also considered to occur frequently. Whilst it is possible both horseshoe species may have been under-recorded during the activity and emergence/re-entry surveys, particularly lesser horseshoe bats which have quiet and very directional calls, the limited results from the Anabats suggest that the horseshoe species only use the SSA infrequently.

Based on the earliest encounters of the species using the SSA and the moderate numbers of each species present, it is considered highly unlikely that a large bat roost is present within the SSA or immediately adjacent to it. However, for some species, the earliest encounters are not long after the typical emergence time, suggesting that off-site roosts may be located in the nearby surrounding area. This is particularly evident in relation to common and soprano pipistrelle, *Myotis* sp. and barbastelle. In addition, the earliest encounters for the common and soprano pipistrelle and *Myotis* sp. are from the southern part of Benhole Lane, which may indicate roosts for these species are located in the villages of Shurton, Burton or Stogursey.

The number of barbastelle records within the SSA was much greater in 2009 than in previous survey years. The most likely explanation for this is not that usage of the site has increased, but rather that the extensive survey effort and presence of recording devices within the SSA during 2009 provided more opportunity to encounter this species. Whilst even with more records it is difficult to fully determine how barbastelle use the SSA, some broad observations can be drawn:

- Whilst barbastelle have not been recorded throughout the SSA, the distribution of records indicates usage of the woodlands and taller hedgerows. It also appears that barbastelle are likely to commute along a short stretch of the minor watercourse in the northern part of the SSA (which provides no tree or hedge cover) to reach the woodland blocks;
- The ‘green lane’ through the centre of the SSA is clearly an important commuting (and possibly foraging) route for this species based on the number of registrations in this location and because barbastelle were often recorded soon after sunset, when most bat species commute to favoured foraging areas;

[9] Distribution patterns of aerial insect accumulations over pasture on the leeward side of hedges has been demonstrated by Rothamsted Experimental Station (Lewis, 1969) and habitat use by foraging and commuting bats is described in British Bats (Altringham, 2003).

- Similarly, the number of records spread throughout the survey period suggests that Benhole Lane is also an important feature for barbastelle;
- The records of barbastelle south and west of Pixies' Mound in combination with the other records within the SSA and from the driving transects suggests that barbastelle may be crossing the existing Power Station access road and travelling east. It is therefore possible that barbastelle are foraging in the mosaic of habitats south of the existing Power Station or commuting to foraging areas further east;
- There is evidence that barbastelle utilise the SSA throughout the night, based on both the early evening and late morning records.

Whilst lesser horseshoe bats have previously been recorded within the SSA (from the desk study information), there are no previous records of greater horseshoe. Nonetheless, the occurrence of both species is no more than occasional and appears to be largely restricted to the 'green lane'. All the greater horseshoe records are also a significant time after sunset and before sunrise and, given that greater horseshoe bats can travel up to 12km from the roost (when habitat is poor in its locality), the roost could be some distance from the site. A number of the lesser horseshoe records are closer to the average emergence time of this species (31 minutes, Altringham, 2003) and lesser horseshoe bats are known to forage primarily within 2km of their roost, but will travel up to 4km (VWT, 2008). Therefore, it seems reasonable to conclude that there is likely to be a roost in reasonable proximity to the SSA, but that the SSA does not form the primary foraging resource for lesser horseshoe bats, as evidenced by the infrequent records.

4.4 Summary Description of the Bat Populations in the SSA

The surveys have shown that the SSA supports at least nine species of bat (when the *Myotis* group is considered as a single species, but this could be as high as 11 if all three suspected species were present) and that the habitats are reasonably well used for roosting, foraging and commuting. The county of Somerset supports a wide range of bat species (15 out of the 16 British bat species are known to regularly occur) and there is a species action plan for 'bats' within the Somerset Biodiversity Strategy.

Within the bat assemblage in the SSA are three species listed on Annex II of the Habitats Directive, namely lesser and greater horseshoe, and barbastelle. Horseshoe species were recorded infrequently within the SSA and it is unlikely that the SSA forms part of the key foraging area or an important commuting route for either species. Also no horseshoe bat roosts were located within the area surveyed. In contrast, the SSA is clearly used on a regular basis (i.e. several times a week) by barbastelle, both commuting and foraging, although, there is only one possible, occasionally used barbastelle roost present. This level of regular activity indicates that the SSA forms a part of a larger territory used by barbastelle.

In addition to the Annex II bat species, the SSA supports a further three species listed on both Section 41 of the NERC Act and as priority species within the UKBAP, namely soprano pipistrelle, noctule and brown long-eared. All these species were recorded frequently within the SSA and it is likely the habitats are used regularly for foraging and commuting. However, there is no evidence of a noctule roost within the SSA and only small roosts of soprano pipistrelle or brown long-eared are likely to occur.

None of the habitat types within the SSA are considered to be of high value to bats because the site is very typical of the surrounding landscape, where hedgerows, small woodlands and agricultural fields are common. However, all the results from the surveys that have been completed within the SSA (both for the new nuclear build and the wind farm) have indicated that the ‘green lane’ through the centre of the SSA is well used by a wide variety of species.

Report template changed for consistency reasons but no other changes have been made since the original issue date.

APPENDIX 20F: HINKLEY 2010 BAT SURVEY REPORT

EDF Energy
Hinkley Point C Bat Survey Report 2010

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station on land to the west of the existing Hinkley Point Power Station complex. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) has been appointed as EDF's ecological consultants to undertake the terrestrial ecological survey and assessment work for the new development.

Extensive bat survey work was completed at the site during 2009 (following more limited surveys in 2007 and 2008), comprising activity surveys, static Anabat monitoring and building and tree assessments. These surveys recorded frequent use of the site by barbastelle and occasional use of the site by both lesser and greater horseshoe bats. There were also records of six other bat species: common and soprano pipistrelle, noctule, serotine, *Myotis* spp. and long-eared bats (the full results of these surveys are reported in the Hinkley 2009 Bat Report, Entec, 2009).

Due to the higher level of legal protection afforded to barbastelle and horseshoe bats (under the Habitat Regulations), their rarity and potential vulnerability to development, it was concluded that further surveys should be completed, targeted specifically at investigating how these species use the wider landscape.

The purpose of this report is to provide a description of the survey methodologies used and detail the results obtained, which are then used to draw conclusions regarding how barbastelle, lesser and greater horseshoe bats may be using the wider landscape.

2. Methodology

2.1 Study Area

A radius of 3km from the site (**Figure 1.1**) was chosen as the study area for the following reasons:

- a variety of habitat types occur, including several blocks of broad-leaved woodland which may provide roosting opportunities;
- surveys could be undertaken to both the east and west of the site to investigate usage in these areas and how bats may travel across the Hinkley Point C site; and
- the survey effort across this area of land could be fairly intensive and cover as much of the area as possible, potentially allowing a level of comparison within the data sets.

2.2 Desk Study

Further information relating to barbastelle in the local area was obtained from the Somerset Bat Group and from the Environment Agency in relation to the Steart Realignment Project.

2.3 Field Surveys

The methodology for undertaking all the bat survey work followed that advised by Natural England (The Bat Mitigation Guidelines, English Nature, 2004) and Bat Conservation Trust Good Practice Survey Guidelines (2007). Sunset times for all the surveys were taken from Metcheck (www.metcheck.com).

The surveys were tailored to investigate usage of the wider landscape around the proposed development site by barbastelle and horseshoe bats (referred to as the 'target species'). Therefore, whilst other species of bat were recorded during the transect and static surveys, these are treated as incidental survey results within this report and are only briefly summarised in the results section.

2.3.1 Static Emergent / Re-entry surveys

The results of the 2009 bat surveys indicated that barbastelle was unlikely to be roosting within the proposed development site due to the lack of suitable habitats and that the earliest times this species was recorded on site in the evening was at least 60 minutes after sunset. However, on a number of occasions barbastelle was recorded within the site reasonably soon after sunset (between 60 and 120 minutes after sunset) and, as there is potentially suitable habitat for roosting within 3km of the site, it is possible that a barbastelle roost could occur within this distance. Therefore, areas of potentially suitable roosting habitat within 3km were sampled using emergence / re-entry surveys.

One emergence / re-entry survey was completed each month between May and September 2010, with each survey focusing on a different woodland block(s). Each survey was completed by two surveyors stationed at two nearby static locations. **Figure 2.1** illustrates the locations of the survey points.

The emergence surveys started around dusk and lasted between 1.5 and 2 hours. The re-entry surveys started 2 hours before dawn and finished at dawn. During each survey the woodlands were watched for bats entering or exiting. Bat calls were recorded using frequency division bat detectors (e.g. Batbox duet or Pettersson D-230) and recording devices (e.g. an Edirol R09), with the recordings being subsequently analysed using BatSound.

The dates of the surveys and weather conditions are provided in **Table 2.1**.

Table 2.1 Emergence / Re-entry Survey Dates and Weather Conditions

Survey Location	Date	Weather Conditions
1 a & b	18th and 19th May 2010	Dry, light winds and cloudy (100% cloud cover). Temperature 12°C – 11°C.

Survey Location	Date	Weather Conditions
2 a & b	8th and 9th June 2010	Dry, light and cloudy (80% cloud cover). Temperature 15°C – 13°C.
3 a & b	13th and 14th July 2010	Dry, light winds and partly cloudy (50% cloud cover). Temperature 18°C – 16°C.
4 a & b	23rd and 24th August 2010	Dry, light to moderate winds and partly cloudy (30% cloud cover). Temperature 18°C – 12°C.
5 a & b	15th and 16th September	Dry, light to moderate winds and cloudy (80-100% cloud cover). Temperature 15°C – 14°C.

2.3.2 Walked Activity Surveys

Walked transect surveys aimed at sampling bat activity at a variety of habitats surrounding the site were completed during May and September 2010. Two transect surveys were completed each month; one route sampled land to the east of the site and the other route sampled land to the west of the site. **Figures 2.2a &b** shows the transect survey routes.

During each survey the transect was walked at a steady pace and bat calls were recorded using frequency bat detectors (e.g. Batbox duet or Pettersson D-230) and recording devices (e.g. an Edirol R09), with the recordings subsequently being analysed using BatSound. Notes were made of the likely bat species, the location of the registration and other details (where discernable) such as direction of flight, activity (e.g. foraging or commuting), number of passes and number of bats.

All surveys commenced around sunset and lasted between 2 and 3 hours to coincide with the time when bats are most active during the night, as this is widely recognised as an optimal time to survey for bat activity. At least one circuit of each transect was completed within this time on each survey visit.

The survey dates and weather conditions of each transect completed are provided in **Table 2.2**.

Table 2.2 Activity Survey Dates and Weather Conditions

Transect Route	Date	Weather Conditions
May		
East	20th May 2010	Dry, light winds and clear (0% cloud cover). Temperature 15°C – 14°C.
West	27th May 2010	Dry, moderate winds and clear (0% cloud cover). Temperature 13°C – 12°C.
June		
East	21st June 2010	Dry, light winds and partly cloudy (20% cloud cover). Temperature 15°C – 14°C.
West	22nd June 2010	Dry, light winds and partly cloudy (30% cloud cover). Temperature 17°C – 15°C.

Transect Route	Date	Weather Conditions
July		
East	6th July 2010	Dry, calm and cloudy (80% cloud cover). Temperature 17°C – 15°C.
West	19th July 2010	Dry/light rain, moderate winds and cloudy (100% cloud cover). Temperature 18°C – 17°C.
August		
East	2nd August 2010	Dry, light to moderate winds and partly cloudy (20% cloud cover). Temperature 17°C – 15°C.
West	9th August 2010	Light rain, calm and cloudy (80% cloud cover). Temperature 18°C – 17°C.
September		
West	1st September 2010	Dry, light to moderate winds and partly cloudy (20% cloud cover). Temperature 16°C – 15°C.
East	13th September 2010	Dry, moderate winds and cloudy (80% cloud cover). Temperature 17°C – 15°C.

2.3.3 Static Bat Detectors (Anabat)

Similar to the other surveys completed, the Anabat surveys were designed to sample barbastelle and horseshoe activity around the proposed development site (particularly to the east and west).

During each survey period between May and October 2010, the Anabats (model ref. SD1) were deployed in pairs at a designated location. The aim of using two Anabat in relatively close proximity to each other was to investigate whether it could be shown that bats were travelling along a habitat feature (e.g. a pass could be recorded by one Anabat and then shortly after by the second Anabat). Anabats were left in place for approximately one to two weeks; however the duration of recording was dependant on the battery life. Hi-mics were used so that the microphones could be placed between 1m and 2m above the ground and sensitivity levels were maintained at around 5 to filter out disturbance, for example from rustling leaves, but to ensure fainter calls would trigger the unit to record.

Whilst the intention was to survey areas east and west of the site equally, initial access restrictions to the west of the site prevented this from occurring. However, additional survey effort was instead employed at a number of locations along the proposed development site boundary, namely along the shore and the western site boundary (as this was the furthest west that access was permitted initially). Hence, the 2010 surveys focused on three main areas (**Figure 2.3**):

- On-site (Shore 1 and 2 and West 1 and 2);
- East of the site (East 1, 2, 5 and 6); and
- West of the site (West 4, 5, 6, 7 and 8).

Table 2.3 shows when the units were deployed at each location and why this location was chosen for the survey.

Table 2.3 Anabat Locations, Deployment Dates and Rationale for Site Selection

Location Reference	Dates (inclusive)	Number of Days Sampled in each Location	Reason for Location
On-site			
Shore 1	06.07.10 - 17.07.10	12	The Shore 1 and 2 Anabat locations were chosen to investigate barbastelle usage of the coastal grassland / cliff habitat, which this species is known to exploit in other areas of its range in the UK (e.g. Suffolk).
Shore 2	03.08.10 - 18.08.10	16	
West 1	26.05.10 - 06.06.10	27	West 1 and 2 are located on Benhole Lane, but were not surveyed in 2009. West 1 was located in a valley and at the junction of hedgerows near to a small stone barn known to be used by *Pipistrellus* and *Myotis* spp. West 2 was sited at the location that the Bum Brook crosses Benhole Lane.
	19.07.10 - 02.08.10		
West 2	26.05.10 - 09.06.10	43	
	26.06.10 - 09.07.10		
	18.08.10 - 31.08.10		
East of site			
East 1	11.05.10 - 22.05.10	24	East 1 and 2 were located near to the mosaic of semi-natural habitat to the south of the Hinkley Point B Station. East 1 was located in trees set back from the coast by 20m and East 2 was located in trees near to a large reed-dominated pond.
	08.07.10 - 20.07.10		
East 2	11.05.10 – 24.05.10	43	
	03.08.10 - 18.08.10		
	01.09.10 - 13.09.10		
East 5	09.06.10 - 21.06.10	28	East 5 and 6 were located at each end of a short north/south lane bounded on each site by a dense hedgerow (a ‘green lane’). East 5 was located at the junction of this lane with a prominent east/west hedgerow forming the boundary of Wick Moor; East 6 was located near to the village of Wick and the network of hedgerows present there.
	20.07.10 - 03.08.10		
East 6	22.06.10 - 03.07.10	14	
	18.08.10 (single night due to Anabat failure)		
West of site			
West 3	21.09.10 - 28.09.10	23	West 3 was sited at the junction of two prominent hedgerows, one of which is the western end of the same hedgerow forming the ‘green lane’ within the site.
	5.10.10 - 10.10.10		
	11.10.10 -19.10.10		
West 4	28.09.10 - 05.10.10	23	West 4 was located adjacent to the Bum Brook upstream from location West 2, in order to investigate whether barbastelle may be commuting and/or foraging along this feature.
	6.10.10 - 10.10.10		
	11.10.10 - 21.10.10		
West 5	14.09.10 - 21.09.10	23	West 5 and 6 were located on hedgerows that connect to the wider landscape via further hedgerows and small copses to the south and west of the site.
	28.09.10 - 04.10.10		

Location Reference	Dates (inclusive)	Number of Days Sampled in each Location	Reason for Location
	05.10.10 - 12.10.10		
West 6	21.09.10- 28.10.10	29	
	05.10.10 - 12.10.10		
	21.10.10 - 02.11.10		
West 7	27.09.10 - 01.10.10	23	West 7 was positioned adjacent to the Bum Brook, a possible commuting / foraging route, and Honibere Wood, a possible roost location.
	12.10.10 - 20.10.10		
	21.10.10 - 29.10.10		
West 8	27.09.10 - 05.10.10	25	West 8 was sited adjacent to Honibere Wood, at a location where it meets a minor road and hedgerows.
	12.10.10 - 17.10.10		
	18.10.10 - 27-10.10		

The Anabat recordings were analysed to identify the species present using Analook software. Due to the large number of bat registrations recorded by both Anabats, the analysis has been restricted to identifying calls from the target species (barbastelle, lesser horseshoe and greater horseshoe).

3. Results

3.1 Desk Study (target species only)

Prior to the 2007 bat surveys at the site there were no records of barbastelle bats from the proposed development site or the wider area, apart from the known maternity colony on Exmoor (~25km to the west). In 2009 the Somerset Bat Group undertook one evening survey at Hodder’s Combe (on the Quantocks) and recorded barbastelle (verified by the Bat Conservation Trust). In 2010 further surveys were completed in Hodder’s Combe and Holford Combe (also located on the Quantocks), which recorded 11 probable barbastelle passes over three visits to each combe during August and September (Pickersgill, 2010). No further detail in relation to the records is currently available (e.g. time after sunset).

During 2010 a range of bat surveys were also completed by Halcrow in support of the Environment Agency’s Steart Realignment Project (Halcrow, 2010). The surveys were predominantly walked transects, with Anabats left out for single nights during the dusk and/or dawn surveys. There were no records of barbastelle during the transect surveys. However, barbastelle activity was recorded on 7 of the 18 Anabat survey occasions (39% of survey time), with the greatest number of passes recorded on the 9 and 10 August 2010. During these peaks of activity, the passes are spread fairly evenly through the night, with short peaks of activity comprising a small number of calls close together, possibly suggesting foraging bouts. Most of the activity was recorded in the western part of the Steart survey area (nearest to the HPC proposed development site), with small numbers of passes along the River Parrett.

3.2 Field Study (target species only)

3.2.1 Emergence/Re-Entry Surveys

None of the target species (i.e. barbastelle or horseshoe bats) were observed entering or exiting the woodlands surveyed. However, during the June survey a barbastelle bat was recorded shortly after sunset (26 minutes). Although, it was still light at this time, the area under the trees was darker. Given that this species generally prefers dark commuting and foraging areas, it is likely that the barbastelle roosted in this woodland and was foraging under the canopy in order to maximise foraging time. This is typical behaviour of barbastelle during the summer when they leave roosts whilst it is still light (Greenaway, 2001).

Table 3.1 details the small number of target bat species registrations recorded.

Table 3.1 Target Species Records from the Emergence / Re-entry Surveys

Date	Location	Species	Minutes after Sunset or before Sunrise
May	1b	Greater horseshoe	71 minutes before sunrise
June	2b	Barbastelle	26 minutes after sunset
July	3a	Barbastelle	Two calls 84 minutes prior to sunrise
September	5a	Lesser horseshoe	93 minutes after sunset

3.2.2 Activity Surveys

Barbastelle was recorded on three occasions during the walking activity transect surveys (**Table 3.2**). All the registrations were recorded during the May transect routes, with one probable call (the call was indistinct but showed similarities to characteristic barbastelle calls) to the east of the site in Stolford and two definite calls near Honibere Wood to the west of the site. All the calls were at least one hour after sunset and the record to the east of the site was later than the calls to the west.

Neither species of horseshoe bat was recorded during these surveys.

Table 3.2 Target Species Records from the Transect Surveys

Date	Location (Figure 3.2a&b)	Species	Minutes after Sunset
May – East transect	Whitewick Lane, Stolford (ST 2338 4527)	Barbastelle (probable)	115 minutes
May – West transect	Honibere Farm Lane (ST 1848 4362)	Barbastelle	71 minutes
	Honibere Wood (ST 1814 4419)		87 minutes

3.2.3 Static Bat Detectors (Anabat)

A summary of the results from the Anabat surveys in relation to the target species is provided below, with more detailed baseline results provided in **Appendices A and B**.

Barbastelle

Barbastelle bats were recorded at all the Anabat monitoring locations in 2010, with the exception of East 1 and East 6. The number of passes recorded at each location, and during each survey month, varied greatly between 2 passes up to 305 passes per survey period. **Table 3.3** summarises the baseline data and draws broad conclusions based on the results.

Table 3.3 Barbastelle Records from Static Anabat Surveys

Location (Figure 2.3)	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
On-site				
Shore 1	July	2	Bats were present on only a single night in 12 days of survey (i.e. 8% of the nights). From the proximity to each other, both passes may have originated from the same bat.	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
Shore 2	August	20	Bats were present on 33% of the nights. Peak of activity was around 14th August (with 13 passes between 2.00-4.00am). All passes were in the AM period.	The cluster of calls on 14th August suggests foraging activity, although the other records are individual or small numbers of passes, more indicative of commuting.
West 1	May/June July/August	25	No bats were present in 13 days of survey in late May. Bats were present on 37% of the nights during the July survey and concentrated on 20-24th July, with some calls occurring together over a short space of time.	Data indicates both foraging and commuting activity at this location during July and August. The absence of calls in May/June may suggest seasonal usage of this area
West 2	May/June June/July	11	Bats were present during 25% of the nights during the late May / early June survey. Passes were spread throughout the survey period with small clusters of calls on certain nights (e.g. five calls between 1-4am on the 27th May). No bats were recorded in 15 days of survey in late June/July.	Data indicates commuting and probable foraging activity at this location (or in the nearby area), as indicated by regular calls over a single night. The absence of calls in late June and July and the large increase in calls during August may suggest seasonal usage of this area, potentially associated with a seasonal food resource.
	August	160	Very active period of 160 passes in 14 nights of survey in August. Bats were present on 71% of the nights. Activity concentrated on 19th and 23rd to 27th August. Clusters of calls during a	

Location (Figure 2.3)	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
			number of nights, e.g. 21 passes between 12.30 and 5.00am.	
East of site				
East 1	May July	0	No bats were present in 12 days of survey carried out in May and 13 days in July (25 days in total).	The data suggest this location does not form part of a core foraging territory but, as barbastelle occur in the area, the location may be used on an infrequent basis.
East 2	May	305	Very active period; 305 passes in 14 days. Bats were present on 78% of the survey nights. Peak of activity concentrated between 14th and 20th between 22.00pm and around 01.00-03.00am each night Clusters of calls during a number of nights, e.g. 62 passes between 10pm and 2.30pm on 17th May. Number of passes in quick succession may suggest multiple bats.	The high level of activity recorded during May and limited activity recorded later in the year, suggests this location is used seasonally, possibly in response to a seasonally available food source (which may be associated with a large reed - dominated pond adjacent to the Anabat location). Due to an abundance of food, the area may be visited by multiple bats early in the active season. For the remainder of the year, this location appears to be used infrequently and probably only by commuting bats.
	August September	4	Bats were present on 23% of the nights during the August survey. The activity was spread over the survey period, with single calls on four nights. No bats were present in 15 days of survey during September.	
East 5	June July/August	37	No bats were present in 13 days of survey during June. Bats were present on 50% of the nights during the July/August survey period and the majority of these passes were concentrated between 27th and 29th July (11 passes on the 28th July).	The cluster of calls recorded in late July suggests this location is occasionally used by foraging or commuting bats.
East 6	June/July August	0	No bats were present in 14 days of survey carried out in late June/early July or in August.	The data suggest that this location does not form part of a core foraging territory or commuting route but, as barbastelle occur frequently in the area, the location may be used on an infrequent basis.
West of site				
West 3	September	39	Bats were present on 62% of the nights during September of which the majority of passes (86%) were concentrated on the 21st and 22nd September.	Data from September suggests foraging activity on two nights, with the area more regularly used by commuting bats.
	October	5	All calls were recorded in a single night (8th October), between 9pm and 12.30am.	

Location (Figure 2.3)	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
West 4	September/ October	148	Very active period, with bats present on 72% of the survey days, with 111 passes in 6 days between 28th September and 6th October. Only single passes recorded in mid-October.	Data indicates commuting and probable foraging activity at this location (or in the nearby area), as indicated by regular calls over consecutive nights, possibly in response to a seasonally available food source.
West 5	September/ October	55	Bats were present on 44% of the nights surveyed (none were recorded during eight days of survey in mid-September). Passes were spread through the survey period but peak on the 7th (10 passes between 1am and 6am) and 8th October.	Data indicates commuting and probable foraging activity at this location (or in the nearby area), as indicated by regular calls over a single night.
West 6	September/ October	11	Bats were present on 20% of the nights surveyed. Small numbers (three or less) of calls recorded on each night.	The low number of calls suggests this location is used primarily for commuting during the survey period.
West 7	September/ October	6	Bats were present on 13% of the nights surveyed. Small numbers (three or less) of calls were recorded on each night.	The low number of calls suggests this location is used infrequently for commuting during the survey period.
West 8	September/ October	2	Bats were present on 10% of the nights surveyed. Single passes were recorded on each night.	The low number of calls suggests this location was used infrequently for commuting during the survey period.

* Full details in **Appendix A**

The results show that the area surveyed around the proposed development site is regularly used by barbastelle. However, the results indicate that the level of usage may vary throughout the year. For example, a large number of passes was recorded at East 2 in May, with a very small number recorded later in the year; a similar pattern was recorded at West 2. The differences in usage are likely to be in response to food availability at certain locations at certain times of year.

The results also show that some landscape features are likely to be attractive to barbastelle throughout the year, for example because they provide a consistent foraging resource or because they offer a suitable linear corridor. One such feature is the Bum Brook, which had high levels of activity throughout late summer at West 2 (August) and West 4 (September/October). It is notable that the Anabats at West 7 (the highest upstream location on the Bum Brook, adjacent to Honibere Wood) recorded very little activity in September/October when West 4 was very active. This may suggest that barbastelle access the Bum Brook corridor at a location between West 7 and West 4.

The vast majority of the passes were recorded at least 60 minutes after sunset or before sunrise (**Appendix A**), which means that primary roosting sites (such as maternity roosts) are not likely to be in close proximity to the survey locations and that bats are travelling from a roost site to the survey area. However, the data provides no indication of the likely direction from which barbastelle are travelling to reach the survey area, as many of the survey points that were furthest from the site recorded little activity, with the exception of survey location West 5, which had moderate levels of activity during the same period of high activity at West 4.

Greater Horseshoe

Greater horseshoe bats were recorded from 9 of the 14 survey locations, with the greatest number of passes recorded at West 6 during the survey in September/October. **Table 3.4** summarises the baseline data and draws broad conclusions based on the results.

Table 3.4 Greater Horseshoe Records from Static Anabat Surveys

Location	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
On-site				
Shore 1	July	3	All calls were recorded around midnight; two calls three minutes apart on a single night and a third call eight days later	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
Shore 2	August	0	No greater horseshoe (GHS) calls recorded	The data suggest this location does not form part of a core territory or commuting route but, as greater horseshoe occur in the area, the location may be used on an infrequent basis.
West 1	July	3	Single passes on three nights in late July. Earliest pass 89 minutes after sunset on 24th July	Limited use of this location during the survey, restricted to commuting
West 2	May	7	Three passes over three minutes on 25th May and four passes over eight minutes on 31st May	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
East of site				
East 1	July	1	One pass 82 minutes after sunset	Very occasional use of this area, restricted to commuting by single bats
East 2	August	1	One pass around midnight in mid August	Very occasional use of this area, restricted to commuting by single bats
East 5	July	1	One pass 109 minutes after sunset	Very occasional use of this area, restricted to commuting by single bats
East 6	June/July August	0	No GHS calls recorded	The data suggest this location does not form part of a core territory or commuting route but, as greater horseshoe occur in the area, the location may be used on an infrequent basis.

Location	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
West of site				
West 3	September / October	0	No GHS calls recorded	The data suggest this location does not form part of a core territory or commuting route but, as greater horseshoe occur in the area, the location may be used on an infrequent basis.
West 4	September / October	2	One pass each on two separate nights, 12 nights apart (earliest 86 minutes after sunset)	Limited use of this location during the survey, restricted to commuting
West 5	October	3	All calls on separate nights, over a period of eight days. Earliest pass 38 minutes after sunset on 3rd October	Limited use of this location during the survey, restricted to commuting
West 6	September / October	8	One or two passes on six nights in late September through to late October. All but one of the passes between 1am and 3am in the morning.	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
West 7	September / October	0	No GHS calls recorded	The data suggest these locations do not form part of a core territory or commuting route but, as greater horseshoe occur in the area, the locations may be used on an infrequent basis.
West 8	September / October	0	No GHS calls recorded	

Greater horseshoe bats were recorded on 21 nights, equal to 6% of the nights that were surveyed, suggesting the use of the area by this species is infrequent The majority of the records comprised single registrations which were likely to be associated with either commuting or very short foraging activity. The greatest levels of activity were recorded from the southern static survey locations (e.g. West 2 and West 6), with only single or no passes from the eastern and western survey locations.

Lesser Horseshoe

Lesser horseshoe bats were recorded from 8 of the 14 survey locations, with the greatest number of passes recorded at West 5 during the survey in September/October. **Table 3.5** summarises the baseline data and draws broad conclusions based on the results.

Table 3.5 Lesser Horseshoe Records from Static Anabat Surveys

Location	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
On-site				
Shore 1	July	0	No lesser horseshoe (LHS) calls recorded	The data suggest these locations do not form part of a core territory or commuting route but, as lesser horseshoe occur in the area, the locations may be used on an infrequent basis.
Shore 2	August	0	No LHS calls recorded	
West 1	July	0	No LHS calls recorded	
West 2	June August	2	One pass in early June and one in late August. Both calls around 2am.	Limited use of this location during the survey, restricted to commuting
East of site				
East 1	May	1	Single pass recorded 172 minutes after sunset	Limited use of this location during the survey, restricted to commuting
East 2	August	0	No LHS calls recorded	The data suggest these locations do not form part of a core territory or commuting route but, as lesser horseshoe occur in the area, the locations may be used on an infrequent basis.
East 5	July	0	No LHS calls recorded	
East 6	June/July August	0	No LHS calls recorded	
West of site				
West 3	September	3	Single passes over three consecutive nights in late August, earliest 153 minutes after sunset	Limited use of this location during the survey, restricted to commuting
West 4	October	8	One or two passes during seven nights in early-mid October. Earliest pass 35 minutes after sunset on 3rd October.	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
West 5	September / October	20	Recorded over five nights in early-mid October, with the maximum number of passes being seven over a duration of 45 minutes on the 5th October. The first pass on each night ranged from 23 to 190 minutes after sunset.	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
West 6	September / October	12	One or two passes during nine nights between late September and late October (final pass on 1st November). Earliest pass 66 minutes after sunset on 6th October. Latest pass on following night at 46 minutes before sunrise.	Limited use of this location during the survey, restricted to commuting or opportunistic foraging

Location	Month	Total Number of Passes	Summary of Baseline Data*	Interpretation of Baseline Data
West 7	October	4	Two passes in close proximity on two nights in late October	Limited use of this location during the survey, restricted to commuting or opportunistic foraging
West 8	October	4	Single passes during October, with the earliest registration 88 minutes after sunset.	Limited use of this location during the survey, restricted to commuting

Lesser horseshoe bats were recorded on 33 nights, equal to 9% of the survey nights, suggesting the use of the area by this species is infrequent. All but three of these registrations were from the ‘west of site’ survey points, with the greatest number of passes recorded at West 5 and West 6. Given the low number of registrations per night, activity in this area is likely to be primarily commuting, with infrequent foraging.

3.3 Field Study (non-target species)

The locations that the following species have been recorded are shown on **Figures 3.1a&b** and **3.2a&b**.

Common Pipistrelle
Common pipistrelle was the most frequently encountered bat species within the site during the surveys and was recorded on all of the transect and static emergence / re-entry surveys. Although the registrations were recorded fairly evenly throughout the survey area, higher concentrations of occurrences were recorded around Stolford to the east of the site, with a lower number of registrations to the west, although passes were frequent on the track from Honibere Farm north towards Knap Plantation Woodland.

Soprano Pipistrelle
Soprano pipistrelle was the second most frequently encountered bat species within the site during the surveys. The registrations of this species were also fairly evenly spread throughout the survey area, with slightly more passes recorded near to villages and farms, such as Stolford.

Nathusius’ Pipistrelle
Nathusius’ pipistrelle was recorded on only one survey occasion. A total of eight passes were recorded during the July transect survey to the east of the site. All the passes were recorded within a 10 minute period from the coastal path to the west of Stolford (around Great Arch).

Noctule
Noctule bats were recorded on over half of the survey occasions. A high number of registrations were recorded at Honibere Wood in May, between Wick and Stolford during the July transect survey, and west of Stogursey during August. Whilst many of the registrations are single passes, suggesting commuting activity, the number of passes close together during the May and July surveys indicates foraging activity.

Serotine
Serotine bats were recorded infrequently during the transect surveys, with a small number of registrations around Stolford and to the west of Stogursey (18 in total). A greater number of registrations was recorded during the static surveys, although on most occasions only one or two passes were recorded during each survey. The exception was the August survey at New Barn Wood when 20 serotine passes were recorded. Most of the activity recorded indicates commuting behaviour, although foraging took place on a small number of occasions.

Leisler's
Leisler's bats were recorded very rarely during the surveys, with the only confirmed occurrence of this species during a dawn survey in May at Honibere Wood. A total of five passes was recorded and the behaviour suggests it was a single bat foraging near to the woodland.

Long-eared
Long-eared bats were recorded infrequently during the surveys, which is not unusual due to their quiet echolocation call. The records were distributed across the survey area, with a small number of records at Chalcott Farm near Stolford, and Standard Copse north of Stringston. A slightly higher number of registrations were recorded during the static survey at Wick Park Covert (five passes in total).

***Myotis* spp.**
Myotis spp. were recorded regularly during the surveys, on almost every survey occasion and in a variety of habitat types. Peaks of activity (where more than one or two passes were recorded) were recorded near Honibere Farm, New Barn Wood (both to the west of the site) and Wick Park Covert (to the south east of the site). A total of 20 *Myotis* spp. passes was recorded during the June static survey at Wick Park Covert.

APPENDIX 20G: HINKLEY DORMOUSE SURVEY REPORT

EDF Energy
Hinkley Dormouse Survey Report

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as 'Hinkley C') on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds. This report details the results of dormouse surveys that were completed between 2007 and 2009.

1.2 Background to Development

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. The 2007 survey was restricted to land owned or controlled by British Energy (which is now part of EDF Energy). When the dormouse surveys were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1). The boundary of the SSA was therefore used to define the area within which the 2009 dormouse survey was carried out. As a result of the 2007-2009 surveys, all habitat features within the SSA that were potentially suitable for dormouse were surveyed. The SSA includes all of the land within the final 'Construction Boundary'.

1.2.2 Site Description

The majority of the land within the SSA is agricultural; comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small, rectangular broad-leaved woodlands are located within the northern part of the SSA and a square block of young broad-leaved plantation has been created in the central part of the area, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA. Two watercourses flow west to east through the SSA (further seasonal ditches also occur) and a further watercourse is present on the southern boundary of the SSA. Three ponds occur within the SSA.

The SSA is adjacent to the Bristol Channel. A low cliff, between 0.2m and 10m in height, forms an escarpment between the land and sea.

The land immediately adjacent to the west SSA is similar in character to that within the western part of the SSA, i.e. it comprises agricultural fields (both arable and improved pasture), which are separated by a mixture of intact species-poor and species-rich hedgerows. A small number of ponds occur and the upper reaches of the Bum Brook flow through the area.

The land east of the SSA is different in character to that within the SSA. It forms part of Bridgwater Bay SSSI and comprises large open fields separated by drains, with very few hedgerows present. The fields immediately adjacent to the SSA have been agriculturally improved and are relatively species-poor. However, those fields to the south and east are less intensively grazed and support a more varied sward and have a greater diversity of plant species.

The proposed development falls into the Vale of Taunton and Quantock Fringes Natural Area[1] (English Nature, 1998), which describes the lowland landscape around the major towns of Taunton, Wellington and Minehead between the Quantock Hills, Brendon Hills, Exmoor and the Blackdown Hills. The Natural Area is characterised by a wide variety of habitats and species, including hedgerow and hedgebanks, calcareous grassland, streams, woodland and scrub, nightingale, otter and bats.

The Natural Area immediately to the east of the SSA is the Somerset Levels and Moors Natural Area (English Nature, 1997).

2. Methods

2.1 Desk Study

Contextual information regarding dormouse within the preliminary works area and surrounding land was obtained from the following sources:

- EDF Energy (and British Energy), have conducted a wide range of ecological surveys of their land holding and employ a conservation warden at Hinkley to help manage their land and undertake biological recording);
- Somerset Environmental Records Centre (SERC);
- Somerset County Council (SCC);
- the Environmental Statement (ES) for the Decommissioning of Hinkley A (Magnox, 2006);

[1] The classification of areas of the country into distinct Natural Areas (NAs) was undertaken by English Nature (now Natural England) in order that areas of the countryside identified by unique combinations of physical attributes, wildlife, land use and culture could be grouped together. Overall, 143 NAs, including 24 Coastal NAs have been identified.

- the ES for the proposed West Hinkley Wind Farm (Dulas, 2006);
- the West Somerset Local Biodiversity Action Plan (LBAP); and
- the National Biodiversity Network (NBN) website.

Data from SERC was requested in May 2009 (following an initial request in 2007) to ensure that any additional new records submitted in the intervening period were captured. The 2009 data request included a search area of 3km[2] around the SSA boundary.

2.2 Field Surveys

The survey methodology followed guidance given in The Mammal Society's "Dormouse Nest Tubes" leaflet (no date), as well as general advice given in the Dormouse Conservation Handbook (English Nature, 2006), Dormice (The Mammal Society, 1992) and A Practical Guide to Dormouse Conservation (The Mammal Society, 1989).

2.2.1 Habitat Suitability

During the extended Phase 1 habitat survey (conducted in March 2007 and updated in 2009) it was concluded that the hedgerows and woodlands within the SSA supported a range of plant species and had fairly complex structural diversity. Also, although the woodland blocks are fairly isolated from each other, the network of hedgerows within and around the SSA offers suitable habitat corridors between the woods within the SSA and further areas of woodland outside it.

Further, the plants present within the hedgerows and woodlands include species that are noted as being of value to dormice (Bright *et al*, 2006) such as bramble, hazel, oak and honeysuckle, although only small amounts of the latter three species occur within the SSA.

The combination of these features suggested the woodland and hedgerow habitats could be suitable for dormouse.

2.2.2 Tube Checking

Dormice construct nests during the summer, usually made out of strips of honeysuckle bark woven with leaves. These can occur almost anywhere within a dense hedge or woodland but are usually off the ground in scrub or trees and can be within holes in trees. This habit of nest building can be used to survey for the presence of dormouse. This is achieved by providing suitable places for dormice to build their nests in the form of wooden boxes and/or plastic tubes, which are then checked at regular intervals. The wooden nest boxes are generally used for long-term monitoring as they are more durable and it usually takes longer for dormouse to use them. Tubes are best used to determine presence/absence over a relatively short period of time as they are readily used by dormouse and easy to set out at a site. Therefore, tubes were used at Hinkley.

---

[2] Whilst a 2km radius around a site is the standard desk study area (IEA, 1995), due to the large scale of the proposed development this was extended to 3km with the aim of capturing more data to allow the results obtained to be put in the context of the wider area.

The Dormouse Conservation Handbook (English Nature, 2006) provides a recommended methodology for sampling a site for dormice using nest tubes. Within this method, an index of the probability of finding dormice in tubes in each month between April and November has been developed and the guidance recommends that dormouse absence should not be concluded from an index score of less than 20 (the maximum score is 25). The index is based on using 50 tubes at a site, but the guidance does not relate this number of tubes to the area of the development site. It is not stated in the guidance that a greater number of tubes increases the score obtained, although a paper within Mammal News (Michael Woods, summer 2008) does suggests that double the number of tubes, doubles the index score. The highest probability scores are obtained during May, August and September, relating to early nest building and dispersing sub-adults.

Based on this methodology, a total of 100 tubes were placed in hedgerows and woodlands during May and June 2007 and were checked on a monthly basis between June and November 2007. Due to access restrictions during 2007, only the land within Area A on Figure 2.1 was accessible for the survey. In November 2008 and April 2009, a further 270 tubes were installed in the hedgerows and woodlands within the remainder of the SSA. These were also checked monthly between May and September 2009. Therefore a total of 370 tubes were used within the SSA.

The hedgerows were sampled by placing tubes at 10-25m intervals, however, priority was given to placing tubes in optimal positions (e.g. in fruiting hazels or particularly dense areas of species-rich hedgerow) rather than sticking to this exact spacing in order to maximise the chances of detecting dormouse if present. In the woodlands the tubes were placed in rough grid layouts to sample both edge habitat and central habitat (English Nature, 2006). Figure 2.2 shows the locations of all the tubes located in both the hedgerows and woodlands surveyed in 2007 and 2009. Appendix A contains photographs showing representative locations of the tubes.

In order to effectively check each tube, a quiet and careful approach was made before the entrance was sealed with a cloth. The inside of the tube was then carefully inspected for the presence of nests or animals. Species other than dormouse, such as wood mouse (*Apodemus sylvaticus*), yellow-necked mouse (*Apodemus flavicollis*) and even birds, often use tubes. However, dormouse nests have characteristic features[3] and are relatively easy to identify.

2.2.3 Overall Survey Effort

Using the guidance provided by English Nature (2006) a survey effort score of 20 was achieved in 2007. In 2009, a score of 20 was also achieved. This analysis is based on using 50 tubes during a single survey season. As one hundred tubes were used in 2007 and 270 in 2009, the final effort score is considered to exceed 20. The surveys in both 2007 and 2009 sampled the key months (May, August and September) identified in the guidance as having the highest probability of finding dormice in tubes.

The English Nature guidance suggest that scores of under 20 should not be used to conclude dormice are absent from a site. The survey effort within the SSA is therefore equal to (and possibly exceeds) this threshold and it is therefore reasonable to conclude dormouse presence or absence can be confidently determined.

[3] Although nests in a tube will take on a more flattened appearance.

2.2.4 Other Signs

During each dormice survey visit, other signs of dormice were also searched for, e.g. nests and feeding remains comprising honeysuckle flowers and stripped honeysuckle bark, around the tube locations.

Hazel is very restricted within the woodlands across the SSA such that a nut search was not considered appropriate in the vast majority of locations. However, two areas of woodland within the SSA support a small number of hazel stools and the bases of these were searched for nuts opened by dormice in November 2008 (Figure 2.2). This survey was completed based on the method within the English Nature Guidance which requires 20 minutes of searching within five to ten 10x10m quadrats. Due to the lack of hazel within the woodland compartments, only two quadrats could be surveyed.

2.3 Constraints

The fact that only two quadrats within the SSA were surveyed for hazelnuts does not undermine the findings of the dormouse survey for the reason that the SSA was extensively surveyed using nesting tubes.

3. Results

3.1 Desk Study

Prior to this study, no formal dormouse surveys had been conducted within the SSA and no records were received during the data search (i.e. from SERC). Dormouse surveys were not completed as part of any of the previous ecological survey work undertaken for either the decommissioning of Hinkley A or the proposed West Hinkley Windfarm.

The nearest dormouse records listed on the NBN website to the SSA is 7km to the south-west at Holford on the edge of the Quantock Hills. The record is from 1994. There are three further dormouse records from the Quantock Hills with further records on Exmoor to the west and Taunton to the south.

3.2 Field Survey

The date of each survey event is provided in Table 3.1.

Table 3.1 Dormouse Survey Dates

2007	2009
22 June 2007	27 May 2009
20 July 2007	18 June 2009
16 August 2007	20 July 2009
19 September 2007	25 August 2009
26 October 2007	14 September 2009
29 November 2007	

No dormice were fond in any of the tubes in either 2007 or 2009. No signs of dormouse, such as feeding remains or nests were found.

A relatively high number of the tubes (~40) were utilised by wood mouse during the course of the surveys (often with more than one mouse in each tube). The wood mice constructed loose nests made predominantly of leaves and grass. During the autumn months the tubes were also used as feeding stations (most likely by wood mice again) and rosehips and blackberries were found in them.

4. Conclusions

No dormice or signs of dormice were observed during the course of the survey. Given the number of tubes used over the area available for survey and the number of visits made to the SSA during 2009 and in 2007 (to achieve the score of 20 in both years), it is considered reasonable to conclude that dormice are not present. As such, specific mitigation and enhancement measures for dormouse will not be required.

APPENDIX 20H: HINKLEY OTTER AND WATER VOLE SURVEY REPORT

EDF Energy
Hinkley Water Vole and Otter Survey Report

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as 'Hinkley C') on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds. This report details the results of otter (*Lutra lutra*) and water vole (*Arvicola terrestris*) surveys that were undertaken in 2009. Relevant previous survey work for these species, undertaken in 2007 and 2008, is also summarised.

1.2 Background Information

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. At the time of the otter and water vole surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1). The boundary of the SSA was therefore used to define the main survey area for the 2009 otter and water vole survey work. In addition, however (as is explained in section 2.2.1), a number of 'off-site' watercourses (i.e. situated outwith the SSA) were surveyed for evidence of the use by otter. As such, the otter and water vole survey area referred to in Chapter 11 of the ES incorporates all water features within the SSA (even though the final 'Construction Boundary' covers a smaller area than the SSA) and, for otter, a number of 'off-site' watercourses.

1.2.2 Site Description

The majority of the land within the SSA is agricultural; comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small broad-leaved woodlands are located within the northern part of the SSA and an area of young broad-leaved plantation has been created in the centre of the SSA, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA.

Two minor watercourses flow west to east through the SSA. The sources of both watercourses are located near to the western boundary of the SSA. One watercourse is contained entirely within the SSA as it discharges directly to the sea along the northern boundary, whilst the second watercourse joins to the ditches on Wick Moor to the east. Two further watercourses are present along the southern boundary of the SSA. The first is fast flowing (known as the Bum Brook/Bayley's Brook), whilst the second is a more slow flowing ditch along the north edge of Wick Moor.

Three ponds occur within the SSA, all of which are different in characteristics. One waterbody is a shaded field pond that frequently dries up. The other two never dry out and are dominated by common reed.

Hinkley Power Station and the SSA lie on the boundary of two Natural England Natural Areas[1], reflecting the landscape differences to the east and west of the SSA. To the east lies the Somerset Levels and Moors Natural Area, the boundary of which is marked by the 10m contour line and as a result the Natural Area is characterised by freshwater and coastal habitats and associated species (such as otter and water vole). The SSA and the land to the west is part of the Vale of Taunton and Quantock Hills Fringes Natural Area which is characterised by gently undulating countryside and many streams in small floodplains.

2. Methods

2.1 Desk Study

Existing information regarding water vole and otter within the SSA and surrounding land was obtained from the following sources:

- EDF Energy (and British Energy, which became part of EDF Energy in 2009), which has conducted a wide range of ecological surveys of its land holding and employs a conservation warden at Hinkley to help manage its land and undertake biological recording);
- Somerset Environmental Records Centre (SERC);
- the Environmental Statement (ES) for the Decommissioning of Hinkley A (Magnox, 2006);
- the ES for the proposed West Hinkley Wind Farm (Dulas, 2006);
- Environment Agency's Fourth Otter Survey of England and Wales 2000-2002 (Wessex Region);
- the Somerset Otter Group (James Williams);
- communication with the former British Energy Conservation Warden, Jon Burrell; and

[1] A Natural Area is not a designation, but an area of countryside identified by its unique combination of physical attributes, wildlife, land use and culture. These features are considered by Natural England to give a Natural Area a "sense of place" and a distinctive nature conservation character which NE seeks to sustain.

• communication with the current EDF Energy Conservation Warden, Dick Best.

Data from SERC was requested in May 2009 (following an initial request in 2007) to ensure that any additional new records submitted in the intervening period were captured. A search radius of 3km was used for both searches, although the 2009 data request covered a larger area as it was based on the SSA boundary.

2.2 Field Surveys

2.2.1 Survey Area

Strategic Siting Area

Three water vole and two otter surveys were completed within the SSA, although the 2009 work represents the only comprehensive survey of the area and, as such, effectively updates and supersedes the 2007 and 2008 surveys. The locations of the watercourses and waterbodies that were surveyed between 2007 and 2009 are shown on Figure 2. Table 2.1 lists when each water feature has been surveyed and by whom.

Table 2.1 Survey Dates

Survey Date	Water Features Surveyed (refer to Figure 2)								Surveys Undertaken	Survey Personnel
	1	2	3	4	5	6	7	8		
14, 20 and 25 May 2009	✓	✓	✓	✓	✓	✓	✓	✓	Otter and water vole	Entec - Gemma Lee
10 and 11 September 2008	✓						✓	✓	Water vole	AMEC
16 August 2007	✓	✓	✓						Otter and water vole	Entec - Gemma Lee

Three further features were considered by AMEC (AMEC, 2008). However, these have been consistently dry through all the surveys (they have been considered as dry ditches within the Phase 1 habitat survey) and are likely to hold water only very rarely. Therefore, they have been screened out of the survey as being unsuitable for water vole and otter on this basis.

Off-Site Sampling Locations

During the 2009 surveys, a small number of the larger watercourses in the wider area (up to approximately 5km from the site in line with guidance provided in the Design Manual for Roads and Bridges, 2001) that are either connected to those water features on site, that could form good commuting corridors for otters or that had accessible features that could be well used by otter (e.g. bridges) were sampled to determine whether evidence of otter was present. The aim of the sampling was to gain a snapshot of how otter use the land around the site and from this, to draw conclusions as to how otter may use the water features on site. Whilst the sampling was aimed at collecting information on otter, evidence of water vole was also searched for. Table 2.2 lists the sampling locations and the reason for their selection.

Table 2.2 Off-Site Sampling Locations

Location Number	Location Name	Grid Reference	Reason(s) for Selection
1	North of Stolford	ST2245	Confluence of the larger East and West Brooks, which link to Bum Brook/Bayley's Brook.
2	South Brook, Combwich	ST255435	Larger watercourse flowing west to east that connects smaller watercourses closer to the SSA (around Stolford) to the River Parrett.
3	Bum Brook at Honibere Wood	ST182443	Otter known to occur on the Bum Brook. Site selected to investigate whether otter may travel up Brook and cross to the Kilve Brook catchment.
4	Stogursey Brook at Stogursey Lane	ST188208	The Stogursey Brook flows south to north and connects to the Bum Brook just east of the SSA. Site selected to investigate movement of otter from the south of the site.
5	Kilve Brook discharge	ST144443	Potentially suitable (and accessible) location to confirm otters present on Kilve catchment to west of site.
6	Bayley's Brook	ST194430	Historical records from Shurton (to the north). Site selected to investigate otter usage of the Brook (which joins with Bum Brook) to the south of the site.
7	Newnham Bridge	ST207443	Another sampling point of the Stogursey Brook to investigate if otter are travelling north-south to and from the site via this watercourse.

2.2.2 Water Vole Survey Methodology

The water features were surveyed for evidence of water voles following guidance provided in the Water Vole Conservation Handbook (Second Edition: Strachan & Moorhouse, 2006). This included searching for the following:

- Latrines - comprising a concentration of droppings in discrete locations, often near nest sites, at range boundaries or often use places to enter and exit the water;
- Feeding stations - comprising neat piles of chewed lengths of vegetation, usually up to 10cm in length, on pathways or haul-out locations;
- Burrows - these are typically found along the waters edge and on top of the bank (up to 5m from the waters edge) and are 4-8cm in diameter. Holes on top of the banks often have 'lawns' around them (areas of grazed vegetation);
- Footprints - located in soft mud or silt.

All the surveys were undertaken at the correct time of year for detecting water vole presence, i.e. between March and October when water voles are more active and mark home ranges more often (Strachan & Moorhouse, 2006).

2.2.3 Otter Survey Methodology

During the surveys the following signs, indicating the presence of otter, were searched for in the vicinity of the water features (as described in Chanin, 2003):

- spraints - which are often located on prominent features within the channel or on the bank (e.g. bridges, rocks etc); and
- footprints - located in soft mud or silt.

Additional evidence of otter presence such as the remains of dead fish or potential holt or resting up places were also looked for, but these signs can be difficult to attribute to otter rather than other species such as mink (*Neovison vison*).

The potential for holt or resting sites was also considered in more detail during this survey, as well as potential foraging and commuting routes from other watercourses in the surrounding area (particularly from the River Parrett).

The surveys were undertaken at an appropriate time of year as otters are active throughout the year.

2.3 Survey Limitations

Although the surveys have all been undertaken at suitable times of year, the watercourses within the SSA become quickly overgrown in the spring and summer season due to their small size, shallow depth and levels of nutrient enrichment (deriving from agricultural operations). There is therefore some potential for field signs to be missed. However, as both otter and water vole tend to leave signs in prominent areas, and given that in many locations the surveys have been repeated, it is likely that evidence of presence would have been detected.

The sampling of water features outside of the SSA, particularly for otter, was restricted to public footpaths and roads. Therefore, suitable locations to sample were limited. Nonetheless, as otter leave relatively conspicuous signs, it is likely that evidence would be visible on well used watercourses. Evidence of water vole may not have been visible at specific locations unless a large water vole population was present. Equally, fewer signs would be present on watercourses infrequently used by otter.

3. Results

3.1 Desk Study

3.1.1 Water Vole

SERC hold records of water vole to the west of Branland Copse and within Branland Copse, to the north of Pixies Pond (from 1995/1996). These records may relate to a historical pond in the woods, which is no longer present, or a miss quoted Pixies Pond grid reference.

Water vole has been recorded within the SSA (during *ad hoc* surveys by the British Energy Warden), with evidence found at Pixies Pond in 1995 and 2006 (although what type of evidence was not noted). Water vole was also recorded on rhynes to the east of the existing Power Station in 1995. Possible evidence of water vole in this location (latrine and burrow) was also found in autumn 2008 (Dick Best, *pers comm*.).

Table 3.1 Water Vole Records Provided by SERC in 2009

Site/Location	Grid Ref	Date	Approximate Distance and Direction from SSA
Moat at Stogursey Castle, Bridgwater	ST203426	May-93	2km to the south
12a, St Andrews Road, Stogursey	ST2042	Aug-94	1.5km to the south
Pixies Mound Pond	ST210455	Aug-95	Within
Hinkley (west of Branland Copse, not near to water)	ST205458	1995	Within
Hinkley Point East Rhyne	ST216460	1995	Adjacent (to the east)
Shurton Stream	ST201442	1994 - 1995	200m to the south
Hinkley (Branland Copse, possible at historic pond)	ST207458	1996	Within
ST1943SW	ST190430	15-May-00	1.6km to the south-west
ST1943 SW	ST194432	15-May-00	1.3km to the south-west

Beyond the desk study search area to the east lies the Somerset Levels, which are connected to the SSA via rhynes and the River Parrett. The Levels has been recognised by the UK BAP Water Vole Steering Group as a Nationally Key site for water vole. This is due to the extent of connected reed bed present. The area is known to support high numbers of water vole despite the occurrence of mink (Strachan & Moorhouse, 2006).

3.1.2 Otter

Otter signs have been found to the east of the SSA on the rhynes of Wick Moor and around a waterbody (ST216457), predominantly in the winter months by the former British Energy Warden John Burrell. Footprints are the most common sign, although spraints were found in 1999 and 2004. SERC holds records of otter on Wick Moor to the east of the existing Power Station from 1999 (ST217458).

Table 3.2 Otter Records Provided by SERC in 2009

Site/Location	Grid Ref	Date	Approximate Distance and Direction from SSA
Wick	ST2144	22-Aug-82	-
Near Hinkley Point	ST24D	Nov-85	-
Hinkley	ST216458	-1998	Adjacent (to the east)
Hinkley point, Rhynes on North and Wick Moor	ST217458	18-Feb-99 18-Mar-99 27-Apr-99	Adjacent (to the east)
Bridgwater Bay SSSI/Wick Moor	ST207454	11-Feb-03	Within
Catsford Common/Stolford	ST240457	15-Mar-03	2.3km to the east

The 10km grid square in which the SSA is located (ST n/e) was not surveyed as part of the Environment Agency's Fourth Otter Survey (2007). However, results from the adjacent grid squares show many sites have continued to support otter since the last survey and that new sites with confirmed otter presence have been found. Since the last survey in 1991-1994 there has been a 121% increase in the number of sites used by otter in the Wessex region. The report notes that in grid square ST n/e regular surveys by the Somerset Otter Group indicate the local population is strong and that the Wessex region is an important stage in the recolonisation of the Thames catchment from the densely populated areas in Cornwall and Devon.

More detailed information provided directly by James Williams (Somerset Otter Group) regarding the otter population in the wider area, suggests that the local population may be at carrying capacity, as otters are known to occur on all the major watercourses (including the River Parrett and its catchments to the east of the SSA and on smaller catchment watercourses to the west such as those that discharge at Kilve and Wiliton). As a result of this it is likely the local otters use all of the available watercourses (James Williams, *pers comm*.).

3.2 Field Survey

Figure 2 indicates the location of the water features surveyed for water vole and otter within and immediately adjacent to the SSA, and the sampling locations of water features outside this area. Photographs of the areas surveyed are provided in Appendix A.

3.2.1 Strategic Siting Area (SSA)

Watercourse 1

The watercourse issues at ST197456 within the SSA boundary, then flows east, then north through Whitewall Brake (broad-leaved woodland, ST202460) and into the sea at ST202461. It is approximately 1km in length. The banks are steep (up to approximately 80cm tall) from the origin of the watercourse to Whitewall Brake, from where the channel appears to have been re-profiled and the banks are shallower (around a 45^{o} slope). The banks consist of earth throughout. Approximately 70% of the stream bed has a muddy substrate, whilst in Whitewall Brake gravel predominates. The north-eastern section is culverted under a farm track and footpath (for approximately 3m) into Whitewall Brake. This part of the watercourse has sparse bank-side and channel vegetation. The stream exits the wood and percolates through the unconsolidated rocky shore to the sea.

Watercourse 1 tends to have a steady flow of water estimated at ~20-30cm deep during the wetter, winter months. However, sections of the watercourse dry out completely in the summer and autumn, particularly Section 1 before in turns north into Whitewall Brake. The banks support a range of ruderal and marginal species, which quickly shade the water in the summer. Species present include bramble (*Rubus fruticosus* agg.), creeping thistle (*Cirsium arvense*), great willowherb (*Epilobium hirsutum*), nettle (*Urtica dioica*), hemlock (*Conium maculatum*), hemp-agrimony (*Eupatorium cannabinum*), water figwort (*Scrophularia auriculata*) and fool’s water-cress (*Apium nodiflorum*).

- No evidence of water vole or otter presence was seen on this watercourse during the surveys in 2007, 2008 or 2009.

Waterbody 2 (Pixies Pond)

Pixies Pond is ~12m long by ~8m wide. In 2007 common reed (*Phragmites australis*) covered an estimated 75% of the water surface with an area of open water in the centre, but clearance in 2008 reduced the common reed cover to 40%. The banks are reinforced on the northern side and are shallow (~10cm) around the rest of the perimeter. Bulrush (*Typha latifolia*), meadowsweet (*Filipendula ulmaria*), marsh-marigold (*Caltha palustris*) and water mint (*Mentha aquatica*) occur around the edges of the pond. The pond is surrounded by a small strip of grassland and scrub.

- No evidence of water vole or otter presence was seen here during the surveys in 2007 or 2009.

Watercourse 3 (North Moor Ditch)

The watercourse is ~1m wide and has steep, earth banks up to 70cm in height. The bed of the watercourse is predominantly muddy, with vegetated mud platforms at the base of the banks.

Similarly to Watercourse 1, this watercourse has a steady flow. An estimated 70cm of water was present during March 2007, but the western section dries up during the summer. The east section, around the Sewage Treatment Works retains water throughout the year. The banks are approximately 40-50cm tall and comprise earth.

Section 1 of the watercourse (the west section) is bounded on the north side by scrub woodland and the substrate is predominantly decaying leaf litter. The northern bank is approximately 20cm tall and the southern bank is 40-50cm tall. The southern bank supports a wide range of ruderal and grass species including false oat grass (*Arrhenatherum elatius*), purple loosestrife (*Lythrum salicaria*), bramble, nettle, hemlock and fleabane (*Pulicaria dysenterica*). Duckweed (*Lemna minor*) covers approximately 85% of the water surface and water-plantain (*Alisma plantago-aquatica*) also occurs.

Section 2 of the watercourse (the east section) is dominated by common reed and duckweed with few other species present. The banks are ~30cm tall but are often heavily poached by cattle from the adjacent fields.

- Evidence of mammal runs was found on the banks of the ditch in 2007 and 2009. However, it was concluded that these were created by rabbits and / or badgers as they were too large for water vole. No evidence of water vole or otter was seen in this location during the surveys;

- However, in 2009 an old otter spraint was found on a rock at grid reference ST215455 (see Figure 3). This is located adjacent to a small (and predominantly dry) drain that flows into Watercourse 3. The spraint was located on a rock just before the drain is culverted, by a field gate.

Watercourse 4

Watercourse 4 is approximately 1km in length and flows west to east across the centre of the SSA before joining with the drains on Wick Moor underneath the Power Station entrance road. The watercourse is between 0.5 and 1m wide and varies in depth between 0.2 and 1m.

Section 1 of the watercourse appears to be dry most years and possibly only holds water in very heavy and prolonged rain. The ditch here supports grasses and ruderals.

Section 2 of the watercourse is located within the centre of improved grassland field grazed by cattle. Because of this, the banks are very poached and disturbed and support a limited range of species, with small amounts of hard rush (*Juncus inflexus*), false fox-sedge (*Carex otrubae*), creeping buttercup (*Ranunculus repens*), cocksfoot (*Dactylis glomerata*), fool's-watercress and brooklime (*Veronica beccabunga*) present. The base of the watercourse in this section is silt and mud, which combined with the cattle disturbance, results in limited water clarity. This section of the watercourse dried out significantly between May 2009 and July 2009, such that it no longer flowed and only pools of water were present.

In Section 3 the watercourse forms a boundary between the fields north and south of it. These are also grazed by cattle but at present the poaching is less severe. This section also appears to have been dredged in 2007 or 2008 with the arisings left on the adjacent banks (which are characterised by a ruderal community). The watercourse in Section 3 is bounded by dense hedgerow west of the road which becomes a line of scrub towards Section 2. Vegetation beneath the hedgerow is sparse and the earth at the base is compacted. The bank underneath the hedge is approximately 20cm tall. The bank opposite the hedgerow is generally species-rich, supporting a range of ruderals and grasses including meadowsweet, hard rush, reed sweet-grass (*Glyceria maxima*), false oat-grass and hemlock water-dropwort (*Oenanthe crocata*). Within the channel common reed is locally dominant and patches of starwort (*Callitriche stagnalis*) and water crowfoot (*Ranunculus aquatilis*) occur.

- No evidence of water vole or otter presence was seen here during the surveys in 2009.

Watercourse 5 (Bum Brook & Bayley's Brook)

Approximately 800m of Watercourse 5 was surveyed (the section adjacent to the SSA southern boundary), although the watercourse itself is longer and comprises a combination of Bum Brook and Bayley's Brook which converge within the survey area. Watercourse 5 varies in width and depth but along most of the area surveyed is approximately 1m wide and 30-50cm deep.

Section 1 of Watercourse 5 flows east from Pond 8 (Hinkley Great Crested Newt Report, Entec, 2009) located on Benhole Lane, forming a field boundary between arable and pasture fields. The watercourse is very shaded in this section due to the extensive bank vegetation, which includes bramble, nettle, Himalayan balsam (*Impatiens glandulifera*) and great willowherb with overhanging semi-mature crack-willow (*Salix fragilis*) trees. The banks comprise earth in this location and are ~10cm tall. The water clarity is poor, but the flow is fairly fast. At the east end of Section 1 Bum Brook joins Bayley's Brook underneath a concrete footbridge.

The banks within Section 2 of Watercourse 5 do not support trees and scrub: they are vegetated by rough grassland and hence this section is not shaded. The banks are taller in this Section, being between 50 and 70cm tall, and are a mixture of earth and stone. One bend in the watercourse has been reinforced with a stone wall. The water flow in this Section continues to be fairly fast and the water clarity is good. The base substrate is a mixture of silt and pebbles. Species recorded on the banks include cow parsley (*Anthriscus sylvestris*) and hemlock water-dropwort. Branched bur-reed (*Sparganium erectum*) and fools water-cress occur within the channel.

The west part of Section 3 is very similar to that of Section 2. The east part becomes more shaded as a hedgerow is present on the southern side of the watercourse.

- Evidence of use by otter was found in three locations along Watercourse 5 in 2009 (see Figure 3):
    - Point A - a relatively well used sprainting site is present on a rock within the channel. At the time of the 2009 survey one recent and two older spraints were present;
    - Point B - a further sprainting site was found, also on a prominent rock in the centre of the watercourse. Again, one recent spraint was present, with evidence of older spraints;
    - Point C - a small and old spraint on a rock at the western edge of the reinforced bank.
- No evidence of water vole was found. Small mammal latrines were found but these did not appear to have been from water vole due to their small size.

Waterbody 6

Waterbody 6 is a large pond (~15m x 15m) that is approximately 60% vegetated by common reed with only 40% of the pond surface being open water. Plant species diversity is limited due to the dominance of common reed with small amounts of bittersweet (*Solanum dulcamara*) and great willowherb present. The waterbody is in excess of 1m deep (actual depth could not be determined due to unsafe access around the majority of the pond margins) and the water clarity is poor. The pond has very shallow margins around the edges without proper banks.

- No evidence of water vole or otter presence was seen here during the surveys during 2009.

Waterbody 7

Waterbody 7 is located within a hedgerow boundary adjacent to an arable field. The pond has a mixture of willow and hawthorn (*Crataegus monogyna*) growing in the centre, the bases of which are currently submerged, but this may suggest the pond is prone to drying out regularly. There are very few aquatic or marginal broad-leaved plants and although there are areas of open water the pond has 90% shading from the surrounding scrub and hedgerows. The pond is approximately 20m by 8m in size.

- No evidence of water vole or otter presence was seen here during the surveys in 2008 and 2009.

Watercourse 8

Watercourse 8 comprises a ditch, approximately 850m in length, with an adjacent mature hedgerow to the south. Ruderal vegetation is extensive within the base of the ditch suggesting that it does not hold water with regularity. This is confirmed by the surveys as in autumn 2008 only a small amount of water was present in the base of the ditch and in was completely dry in May 2009.

- No evidence of water vole or otter presence was seen here during the surveys in 2008 or 2009.

3.2.2 Sampling Locations

The results of the otter and water vole surveys at the sampling locations are provided in Table 3.3.

Table 3.3 Results of Off-Site Sampling Surveys

Location	Brief Description	Results
1	The watercourses in this area have a steady flow and are located in steep sided ditches. Stock poaching occurs in some locations. The banks are generally un-mown and species-diverse. The water levels are controlled by sluice gates and several stone bridges cross the ditches.	Probable otter spraint present at the Environment Agency's Great Arch compound, ST228459 (access to confirm was not available). No other signs.
2	The South Brook is a fairly fast flowing, deep watercourse with steep tall banks (~1m tall). The banks are un-mown and support a diverse range of tall grasses and herbs.	No evidence found.
3	The Bum Brook is fast flowing in this location and ~60cm in width. At the survey location the Brook flows underneath a stone bridge and is joined by a south-north drain flowing along the edge of Honibere Wood. Stones are present within the channel.	Probable otter footprints were observed in soft mud underneath the stone bridge (restricted access prevented confirmation). No other signs.
4	The Stogursey Brook is fast flowing and approximately 1m wide. The banks are shallow in this location and the base of the watercourse is a mixture of silt and stone. The watercourse has some rough bankside vegetation and overhanging trees, although the north bank is grazed.	Otter spraint present on large rock ~5m east of the road bridge at the confluence of the Stogursey Brook and minor stream. Several spraints of varying age were present. No other signs.
5	At the survey location the Kilve Brook is fast flowing over a rocky substrate, but is heavily shaded by the adjacent trees and scrub. It is approximately 2m wide and discharges into a large pool just above the high tide mark. A well used car park is present at this location and the Brook is quite disturbed here.	No evidence found.
6	No access was possible. Vegetation obscured the view of the Brook in this location.	-

Location	Brief Description	Results
7	The watercourse here has a steady flow over a mixture of silt and rocks. The banks are fairly steep (~60cm tall) and well vegetated with rough grasses and herbs. Scattered rocks protrude from the water surface. Upstream of the bridge the watercourse is shaded adjacent to a track and garden.	No evidence found.

4. Conclusions

4.1 Water Vole

No evidence of water vole has been found during any of the surveys of the water features during 2007, 2008 or 2009.

Watercourses 1, 4 and 8, and Waterbody 7, are generally shallow (or dry) and often shaded or disturbed by stock. In most locations they also lack wide densely vegetated banks, whilst the watercourses are narrow in width. Whilst these habitat features do not preclude the presence of water vole, deep, quite wide watercourses (at least 1m) and slow flowing water which is not shaded seem to be features more favoured by this species in lowland Britain. Wide vegetated margins and in-channel vegetation are also important for water vole, providing both cover and food (Strachan & Moorhouse, 2006). Therefore, the water features within the site do not provide optimum habitat, which reduces the potential for water vole to occur.

Watercourses 3 and 5, and Waterbodies 2 and 6, have higher potential to be used by water vole as they are slow flowing and often less shaded, with species-diverse banks (which provide potential foraging habitat) which in some places extend several meters from the channel. The watercourses adjacent to the SSA are also better connected to the wider ditch and watercourse network to the east and south, but they provide limited opportunity for movement to the west of the site (i.e. Bum Brook does not connect directly to watercourses to the west).

Nonetheless, the desk study records clearly indicate that water vole do occasionally occur at Pixies Pond (within the SSA) and on water features adjacent and within 3km of the SSA boundary. The irregular records of water vole in these locations could be due to irregular survey effort. However, it seems more likely that the watercourses within the survey area have either:

- not been fully colonised by water vole from the River Parrett catchment and the occasional records relate to dispersing pioneer individuals; or
- have been previously colonised by water vole, but that the population is now absent (e.g. through mink predation), as small populations of water vole are vulnerable to extinction (Strachan & Moorhouse, 2006).

Therefore, as the water features adjacent to the site are hydrologically connected to further areas of suitable water vole habitat to the east and south (e.g. the River Parrett) and provide reasonably suitable habitat themselves, there is moderate potential that water vole could occur on these features in the future. However, given the short lengths of the watercourses within the SSA, their relatively isolated position from the many rhynes to the east of the site and the lack of further connectivity to the west (as all originate within the site), it is concluded that there is only limited potential for water vole to occur on or to colonise Watercourses 1, 4 and 8 and Waterbody 7, even if present nearby.

4.2 Otter

No evidence of otter presence was found within the SSA during any of the surveys. During the 2009 surveys evidence of otter activity was, however, recorded on the Bum Brook/Bayley's Brook adjacent to the southern boundary of the SSA and also on a drain to the south-east of the SSA. Otter presence was also recorded on watercourses that are hydrologically linked to those adjacent to the SSA, located to the west, south and east.

Based on the desk study results, it is unsurprising that otter appear to use most, if not all, of the watercourses around the SSA. Whilst none of the water features surveyed adjacent to the site and in the wider area are particularly large (i.e. could be classed as rivers), all are well connected to further watercourses and areas of wetland habitat. Therefore, they provide ideal commuting corridors. In addition, the faster flowing and larger streams surveyed (e.g. Bum Brook and Stogursey Brook) are likely to support good populations of fish and are therefore likely to be important for foraging as well as commuting.

Although otters will readily travel over land between catchments, the watercourses within the SSA are particularly poorly connected to catchments to the west. Therefore, it is unlikely an otter would use Watercourse 1, 4 or 8 to travel east to west when the Bum Brook provides a greater length of watercourse (which is also well vegetated) and therefore reduces the distance of terrestrial travel to reach the Lilstock/Kilve watercourses to the west. In addition, the smaller partly seasonal water features within the site are unlikely to provide enough resources (such as fish and amphibians) to be used extensively throughout the year.

All the water features surveyed are predominantly undisturbed by human activity and have areas of dense vegetation adjacent which may be suitable be used for as couches[2], although given the ephemeral nature of the watercourses within the site and their limited connectivity to larger watercourses this is unlikely. Given the likely limited resources associated within the water features within the SSA boundary, these are unlikely to be favoured locations for natal holt sites, which tend to be located in close proximity to the most productive areas of the home range. The Bum Brook/Bayley's Brook has greater potential to support a natal holt, although adjacent to the site it is relatively small and shallow and fish are unlikely to be abundant.

It is therefore considered that the water features within the SSA offer limited commuting, foraging or resting/breeding opportunities for otter due to their relatively isolated location and small size and that there is low potential for them to be utilised frequently by otter. The watercourses adjacent to the site (and in the wider area) provide better habitat for otter and are clearly used preferentially (and probably more regularly, given the resources available) by otter to those within the site.

[2] Couches differ from holts by being above ground, often comprising only trampled vegetation. Some couches, in favoured locations, can be re-used regularly, although many are temporary day-time resting places (Chanin, 2003).

APPENDIX 20I: HINKLEY GREAT CRESTED NEWTS SURVEY REPORT

EDF Energy
Hinkley Great Crested Newt Survey Report

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as 'Hinkley C') on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds. This report details the results of great crested newt (*Triturus cristatus*) surveys that were conducted in 2009 in order to inform the assessment.

1.2 Background Information

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. At the time of the great crested newt surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1). The SSA includes all of the land within the final 'Construction Boundary'.

The survey area for the 2009 great crested newt surveys (which effectively updated and superseded surveys that were undertaken in 2007 and 2008) incorporates all water bodies within the SSA or within 500m buffer of its boundary[1].

1.2.2 Site Description

The majority of the land within the SSA is agricultural; comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small broad-leaved woodlands are located within the

[1] English Nature's (now Natural England's) Great Crested Newt Mitigation Guidelines (2001), state that, in the absence of significant barriers to movement (e.g. major roads, residential areas etc.), 500m is the maximum distance that GCNs are likely to travel from their breeding ponds to utilise terrestrial habitat. It is therefore possible that GCNs from water bodies within 500m of the SSA boundary may occur within the SSA and it is for this reason that the survey area was extended 500m from the SSA.

northern part of the SSA and an area of young broad-leaved plantation has been created in the centre of the SSA, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA. Two watercourses flow west to east through the SSA (further seasonal ditches also occur) and a further watercourse is present on the southern boundary of the SSA. Three ponds occur within the SSA and in the wider context; there are seven ponds within 500m of the site boundary. These are mainly relict agricultural ponds which are small in size, shallow, and unmanaged.

2. Methods

2.1 Desk Study

Existing information regarding newts within the SSA and surrounding land was obtained from the following sources:

- EDF Energy (and British Energy, which is now part of EDF Energy) has conducted a wide range of ecological surveys of its land holding and employs a conservation warden at Hinkley to help manage its land and undertake biological recording);
- communication with the former conservation warden, Jon Burrell;
- Somerset Environmental Records Centre (SERC);
- the Environmental Statement (ES) for the Decommissioning of Hinkley A (Magnox, 2006); and
- the ES for the proposed West Hinkley Wind Farm (Dulas, 2006).

Data from SERC was requested in May 2009 (following an initial request in 2007) to ensure that any additional new records submitted in the intervening period were captured. A search area of 3km was used for both searches, although the 2009 data request was based on the larger SSA boundary.

In addition to the data collected from consultees, the 1:10,000 OS map of the area was used to identify water bodies within the SSA and up to approximately 500m from this boundary in both 2007 and 2009.

2.2 Field Surveys

2.2.1 Screening

Five ponds were visited during the 2007 survey and screened using the criteria below. In 2009, all 12 ponds identified during the desk study as being within approximately 500m of the SSA boundary were visited, or revisited, on the 23 April 2009 to determine if they still existed and if they were likely to support great crested newts. The 2009 survey made use of the criteria below, but also incorporated the Habitat Suitability Index (HSI) developed by Oldham *et al*

(2000), which provides a score of the suitability of a pond to support great crested newts and is a recognised tool for highlighting ponds with greatest potential to support this species.

Key features, additional to the HSI assessment, that were considered in the screening exercise included:

- receiving discharge of pollutants at excessive levels or containing anoxic waters;
- insufficient aquatic vegetation or other material that could be used for egg laying;
- extreme levels of fish activity (e.g. an intensively managed fishing lake) or waterfowl activity (where the number of waterfowl present exceeds 10 per $1000m^2$ [Oldham *et al* 2000]);
- links to fast flowing streams, or the presence of an extreme management regime; and
- the lack of suitable connecting features e.g. mature hedgerows, ditches or woodland between the pond and the site that newts could follow or a significant barrier to movement between the pond and the development area.

2.2.2 Presence/Absence

In 2009, presence/absence surveys were carried out at any pond that was considered suitable for newts following screening (and where access was available). Each pond was visited four times (the survey dates are provided in Appendix C), during suitable weather conditions,[2] within the optimum survey period[3] and during which up to three methods of surveying where employed. These were:

- <u>Bottle-trapping</u> - bottle traps made from two-litre polyethylene type bottles were secured to the substrate using a bamboo cane attached through two holes within the plastic bottle. The traps were set at regular intervals around accessible areas of the pond margins. Upon installation, each bottle trap included an air bubble to prevent newts suffocating. The traps were set each evening between 19:30 and 21:30 hours and retrieved between 06:00 and 08:00 hours the following morning;
- <u>Torch-light surveying</u> (using an adequately powerful torch);
- <u>Egg search</u> - marginal aquatic macrophytes were inspected for the presence of great crested newt eggs.

Sweep netting is an additional method that can be used to investigate the presence of newts in a pond. However, this method would have been too destructive at the site given the generally high amount of aquatic vegetation present in the ponds surveyed.

For Pond 1, the 2009 surveys updated a presence/absence survey carried out in spring 2007. The same methodology was employed for both the 2007 and 2009 surveys.

---

[2] As defined in the Great Crested Newt Mitigation Guidelines (English Nature, 2001).

[3] Between mid-March and mid-June (as per the Great Crested Newt Mitigation Guidelines [English Nature, 2001])

2.3 Personnel

The 2007 surveys, pond screening exercise in 2007 and 2009 and first survey event of 2009 were conducted by Entec Ecologist Gemma Lee (Natural England Licence No. 20090830). The final three survey events of 2009 were carried out by Entec Ecologist Caroline Chipperfield (Natural England Licence No. 20092063).

3. Results

3.1 Desk Study

Table 3.1 summarises the great crested newt records provided by SERC.

Table 3.1 Great Crested Newt Records provided by SERC in 2009

Date (s)	Grid Reference	Description of Location	Approximate Distance and Direction from SSA
1993-1994, 1995, 1996	ST207458	The north-west corner of Branland copse and the edge of car park (may relate to a now defunct pond in the wood - see below)	Within SSA boundary
1995	ST210455	Pixies Pond	Within SSA boundary
1995	ST210455	Drain east of Pixies Pond	Within SSA boundary
1995	ST232453	Fields to the east of Stolford	1.6km south-east
1995 (3 records)	ST245452	Fields to the east of Stolford	2.8km south-east

Whilst there are historical records of a pond within Branland Copse, there was no standing water within woodland during the field survey. Within the central western part of the wood (ST207457) is a small ditch system (~10m in length and up to 4m wide), which may have previously held water continuously, however at present, the ditches only contain a small amount of water (~10cm) during the winter and is dry from spring onwards.

Pixies Pond was created in 1992-1993 and supported all three British species of newt; smooth, palmate and great crested (Burrell, 2005). When the pond was first created it contained abundant stonewort, which is a good egg laying plant for newts. However, the pond has been steadily colonised by common reed (*Phragmites australis*), reducing the amount of open water area present. Stickleback fish, which prey on the eggs and larvae of newts, were also introduced to the pond after it was created. These are now present in large numbers. Since 1993 the number of newts recorded within the pond has declined, with only smooth newts noted in more recent years.

In the wider area, there are populations of great crested newt known to occur to the east of the Power Station, around Stolford approximately 2km away (SERC records and John Burrell, *pers. comm.*). Given the network of rhynes within the moors between Stolford and Hinkley, it is possible great crested newt have previously colonised the ponds around the Power Stations via these drainage channels. However, newt eggs can also be transferred between ponds on the feet of wildfowl and therefore it is possible the great crested newts that were present could have originated from further away.

Five ponds were identified from the OS map as being within the SSA boundary with seven further ponds within 500m. Therefore a total of 12 ponds were subject to the screening assessment.

3.2 Screening Assessment

The HSI score for each pond subject to screening in 2009 is shown in Table 3.2. A full breakdown is shown in Appendix B. Table 3.2 also provides a brief description of each pond, highlights whether the ponds were then screened into the surveys or not and outlines the reasoning behind this. The locations of the ponds screened are illustrated in Figure 2.

Photographs of each pond are contained in Appendix A.

The categorisation of HSI scores are as follows:

- <0.5 Poor;
- 0.5-0.59 Below average;
- 0.6-0.69 Average;
- 0.7-0.79 Good; and
- >0.8 Excellent.

Note that Oldham *et al* (2000) states that the lowest HSI score obtained from a pond known to support breeding great crested newts is 0.43.

Table 3.2 Pond Descriptions and Results of Screening

Pond Number	Description	Distance from SSA Boundary	HSI Score	Screening Decision
1 (Pixies Pond)	Common reed covers approximately 30 % of the water surface with blanket weed (*Spirogyra adnate*) present in the remaining area of open water. Bulrush (*Typha latifolia*), marsh-marigold (*Caltha palustris*), meadowsweet (*Filipendula ulmaria*) and water mint (*Mentha aquatica*) also occur around the margins of the pond. Bramble (*Rubus fruticosus agg*.), hawthorn (*Crataegus monogyna*)	Within the SSA boundary	0.42 (poor)	**Screened in.** This pond has supported great crested newt in the past (last recorded 1993) and provides some limited areas of suitable habitat with open water and suitable egg laying media. No great crested newts were recorded in the presence/ absence survey in 2007. HSI score reflects the current deteriorated state of the pond.

Pond Number	Description	Distance from SSA Boundary	HSI Score	Screening Decision
	and blackthorn (*Prunus spinosa*) are present around the edges of the pond. The pond is relatively deep (over 50cm) and approximately 10m x10m in size.			
2	A relatively large water body (~15m by 15m), dominated by common reed around the entire edge of the pond with a small area of open water in the centre. Crack-willow (*Salix fragilis*) trees and blackthorn and bramble scrub occur around the edges, with great willowherb (*Epilobium hirsutum*) common in the vicinity. The pond is of unknown depth. It is frequented by ducks and swans.	Within the SSA boundary	0.38 (poor)	**Screened in**. Surveys were conducted at the pond in 2006 (for the Hinkley A decommissioning ES) with no newts of any species recorded and the HSI score is poor. However the pond is within the SSA and located between Pond 1 and historic records of great crested newt around Stolford.
3	The pond is located adjacent to a hedgerow and at the corner of an arable field. The pond has a mixture of willow and hawthorn growing in the centre, the bases of which are currently submerged, but this may suggest the pond is prone to drying out regularly. There are very few aquatic or marginal broad-leaved plants and although there are areas of open water the pond has 90% shading from the surrounding scrub and hedgerows. The pond is approximately 20m by 8m in size.	Within the SSA boundary	0.53 (below average)	**Screened in.** Although there is potential for the pond to dry out, this can favour newts by removing the fish population, which is reflected in the HSI score. Also, it lies within the SSA and therefore affects on the pond as a result of the development could be greater.
4	A small (~10m by 4m), quite shallow water body (between 0.5 and 1m), the surface of which is 100% covered in floating grasses and algae. The pond lies at the edge of an arable field with approximately 10% shading, and is adjacent to a species-poor hedgerow.	80m to the east	0.54 (below average)	**Screened in.** Although there is potential for the pond to dry out, this can favour newts by removing the fish population which is reflected in the HSI score. Also, the vegetation would provide suitable egg laying media. Hedgerow connection to SSA boundary.
5	This water body is quite small (~8m by 4m) and connected to a drain. The pond was dry.	387m to the west	0.4 (poor)	**Screened out.** The pond is likely to remain dry for the remainder of the season.
6	A small pond (~10 by 10m), fairly deep (approximately 1m), with 100% aquatic vegetation cover and 50% macrophyte cover. The pond is located in the middle of a cattle field with no shading. Ducks observed using the pond.	120m to the east	0.59 (below average)	**Screened in.** The pond is within 500m of the SSA boundary and is a suitable pond, as reflected by its HSI score, for newts. It supports an abundance of egg laying media and is bordered by habitat which could support newts in their terrestrial phase. The pond is also located between Pond 1 and historic records of great crested newt around Stolford to the east.

Pond Number	Description	Distance from SSA Boundary	HSI Score	Screening Decision
7	A fairly large pond (~20 by 20m), possibly an old quarry, with 95% duckweed cover and 10% shading. The pond has very steep sides with dense vegetation.	335m to the west	0.67 (average)	**Screened in.** The pond is within 500m of the SSA boundary and is a suitable pond for newts, as reflected by its HSI score. It supports an abundance of egg laying media and is immediately bordered by good habitat (with further good habitat within 250m) which could support newts in their terrestrial phase. Although 335m distant, the pond is reasonably well connected to the SSA via intact hedgerows.
8	The pond (~30m by 10m) is effectively the pooling of a watercourse at the end of a ford and therefore likely to be occasionally disturbed by vehicles. The base of the pond is stone, there is 10% shading and 10% macrophyte cover.	Within the SSA boundary	0.46 (poor)	**Screened in.** Whilst it appears that vehicles do cross the ford/pond, this is likely to be restricted to the occasional agricultural vehicle, and it is a large enough water body that parts of it are left undisturbed by these activities. Although the HSI score is low, some residual potential remains for it to support great crested newts.
9	The pond is not present. In this location a small watercourse is present with no significant pooling.	Within the SSA boundary	Pond no longer present	**Screened out.**
10	A small (~10m by 4m), but dry pond with approximately 10% shading, adjacent to a species-poor hedgerow.	290m to the east	0.52 (below average)	**Screened out.** The pond is likely to remain dry for the remainder of the season.
11	A small field pond, approximately 5m by 5m, with poor water quality, 100% shading and no macrophytes.	300m to the south east	0.4 (poor)	**Screened in.** The pond is within 500m of the SSA boundary and has some limited potential to support great crested newt should a source population be present in nearby ponds. There is hedgerow connection to SSA boundary.
12	A private small garden pond, 5m by 5m at the most, supporting 90% -100% macrophyte cover.	450m to the south	0.57 (below average)	**Screened out.** The pond is approximately 450m from the SSA boundary and is separated from the SSA by a minor road. The habitat connections between the pond and the SSA boundary are poor comprising four large arable fields and no substantial field boundaries leading to the SSA.

In total 12 ponds were identified either within the SSA boundary or within 500m of it in 2009. Of these, four ponds were screened out; three were dry (Ponds 5, 9 and 10), and one (Pond 12) is over 450m from the SSA boundary with poor habitat connections between it and the SSA.

In total eight ponds were screened in. Of these one pond (Pond 7) could not be accessed safely and thus only seven ponds were subject to further assessment.

Pond 7 could not be bottle trapped, netted or egg searched as the steep sides of the quarry, fringed with dense and continuous bramble scrub, prevented access to the waters edge. Torching was restricted by an abundance of duckweed.

3.3 Presence/Absence Survey

In 2007, bottle trapping, torching and egg searching were successfully carried out on each of the four survey visits at Pond 1.

On each survey visit in 2009, the most appropriate survey methods were employed, which depended on the pond conditions. For example Pond 8 had a stone base and gentle current, which restricted the use of bottle traps, but which was suitable for torch surveying. Ponds 2, 4 and 6 had large areas of vegetation which restricted torching. Although vegetation cover did not prevent torching at Pond 1 it marginally reduced the effectiveness of this survey technique. Pond 11 was very turbid, however, torching was still undertaken as the pond was small and could be adequately covered. Due to its characteristics, Pond 7 could not be surveyed using any of the recommended survey methods (see section 3.4).

Table 3.3 indicates the methods used at each of the ponds that was surveyed on each survey visit in 2009.

Table 3.3 Survey Methods Employed at each Pond Screened into the Presence/Absence Surveys 2009

Pond Name	23/04/09	29/04/09	07/05/09	09/06/09
Pond 1	Torch, trap & egg search	Torch, trap & egg search	Torch, trap & egg search	Torch, trap & egg search
Pond 2	Torch, trap & egg search	Trap & egg search	Trap & egg search	Trap & egg search
Pond 3	Torch, trap & egg search	Torch, trap & egg search	Torch, trap & egg search	Pond dry
Pond 4	Torch, trap & egg search	Trap & egg search	Trap & egg search	Trap & egg search
Pond 6	Torch, trap & egg search	Trap & egg search	Trap & egg search	Trap & egg search
Pond 8	Torch and egg search.	Torch and egg search.	Torch and egg search.	Torch and egg search.
Pond 11	Torch, trap & egg search	Torch, trap & egg search	Torch, trap & egg search	Torch, trap & egg search

No great crested newts were recorded in any of the ponds during the 2009 surveys. The surveys of Pond 1 in 2007 also did not record great crested newts. Based on the survey effort completed, and in accordance with the *Great Crested Newt Mitigation Guidelines* (English Nature, 2001), it is therefore reasonable to conclude that great crested newts do not occur within the water bodies surveyed.

Ponds 2, 3, 6 and 8 support smooth newt and Pond 4 supports palmate newt. Pond 1 also supported palmate newts in 2007 but these were not recorded again in 2009. No newts were recorded in Pond 11.

Fish were recorded in large numbers in Ponds 1 (also in 2007) and 6 and in less abundance in Pond 3. In addition, a large species of diving beetle, which predate on the larva and eggs of newts, was recorded in Pond 1.

Presence/absence results for 2007 are provided in Appendix C and for in 2009 in Appendix D.

3.4 Constraints

The *Great Crested Newt Mitigation Guidelines* (English Nature, 2001) recommend that in order to determine presence or absence of great crested newts within ponds, at least three survey methods (preferably bottle trapping, torching and egg searching) should be employed during each of the four survey visits. As described above, at some of the ponds assessed, less than three survey methods were used during some surveys due to the ponds' characteristics (e.g. extensive vegetation cover, turbidity and concrete bases).

The *Great Crested Newt Mitigation Guidelines* acknowledge that pond conditions can prevent the use of certain methods, but also highlight how effective each survey method can be in the most appropriate circumstances (e.g. bottle trapping can be effective in weedy or turbid ponds and torching can be very effective in clear ponds).

At all but one of the ponds that were surveyed, the full three survey methods were employed on the first survey visit, which was completed during the optimum survey period. Following this, the most appropriate survey methods were used at each pond depending on the characteristics of that pond and, where possible, all three survey methods were used. On the basis that the most appropriate survey methods were used at each pond, there is no requirement for further survey work at any of the ponds.

Pond 7 could not be surveyed using any of the appropriate methods. The likelihood of this pond supporting great crested newts has therefore been reappraised using relevant habitat information and the results of the surveys of other ponds. None of these other ponds support great crested newt and there are no known additional ponds within 500m of Pond 7. The absence of a breeding population of great crested newts within 500m of Pond 7 does not preclude the possibility that it supports a population of this species, although it reduces the likelihood that it does. If it were to support a population, there is good quality terrestrial habitat immediately surrounding the pond, and within 250m of it, whilst the terrestrial habitat within the SSA does not provide any additional resources or exceptional habitat that would be attractive to great crested newts. Therefore, with reference to the *Great crested newt mitigation guidelines* (EN, 2001) which state that "*as a general guide, suitable habitats within 250m of a breeding pond are likely to be used most frequently*", there is low potential that any great crested newts from Pond 7 would travel a minimum of 335m to the SSA and therefore be affected by the works.

The combination of the information set out above lead to the conclusion that great crested newts are not likely to access the development from Pond 7.

4. Summary

The habitat suitability assessment of the ponds produced low HSI scores of 0.59 or less ('below average' or 'poor') for all the ponds, except Pond 7 which scored 0.67 ('average'). The main factors contributing to the scores are the presence of fish and waterfowl, apparent poor water quality, and to a lesser degree shading and the small size of the ponds. Pond 7 scored higher due its larger size and because the presence of fish could not be confirmed (due to the restricted access).

In support of the low HSI scores, no evidence of great crested newts was found within the SSA or in the surrounding area in either the 2007 survey of Pond 1 or in any of the ponds surveyed in 2009. However, these surveys did highlight the presence of smooth newts in Ponds 2, 3, 6 and 8 and palmate newts in Pond 1 (in 2007 only) and Pond 4.

Whilst great crested newts have been historically present in Pond 1 (Pixies Pond) and Branland Copse, surveys over the past ten years have failed to record this species[4]. Great crested newts can survive for several years without breeding when conditions are sub-optimal or ponds dry out; however in this instance it is likely that great crested newt are no longer present in this pond. The HSI score for Pond 1 was 0.42 ('poor') due to the very large fish population and this is likely to restrict breeding for any newt species.

1 (2nd May)	0	0	0	0	0	0	0	0	0
2 (14th May)	0	0	0	0	0	0	0	0	0
3 (15th May)	0	0	0	0	0	0	0	0	**1**♂
4 (21st May)	0	0	0	0	0	0	0	0	**1**♀

Additional Info: frogs and toads present, large numbers of sticklebacks (fish) were recorded during the bottle trapping and torching surveys.

The surveys did not record the presence of great crested newts. Very low numbers of palmate newt were recorded.

Appendix D
2009 Results

Table D.1 Pond 1

Survey Event	Great Crested Newts			Smooth Newts			Palmate Newts			Smooth/Palmate Female Newts
	Eggs	Torching	Trapping	Eggs	Torching	Trapping	Eggs	Torching	Trapping	
1 (23rd April)	0	0	0	0	0	0	0	0	0	0
2 (29th April)	0	0	0	0	0	0	0	0	0	0
3 (7th May)	0	0	0	0	0	0	0	0	0	0
4 (9th June)	0	0	0	0	0	0	0	0	0	0

Additional Info: Large numbers of sticklebacks (fish) and diving beetles were recorded during the bottle trapping and torching surveys. Ducks and swans also present.

The surveys did not record the presence of any newt species. No eggs of any species found. Although vegetation did not prevent torching it marginally reduced the effectiveness of this survey technique.

Table D.2 Pond 2

Survey Event	Great Crested Newts			Smooth Newts			Palmate Newts			Smooth/Palmate Female Newts

APPENDIX 20J: HINKLEY REPTILES SURVEY REPORT

EDF Energy
Hinkley Reptile Survey Report

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as ‘Hinkley C’) on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, other than coastal/marine biodiversity with the exception of birds. This report details the results of reptile surveys that were conducted in 2008 and 2009 in order to inform the assessment. Relevant previous survey work for these species, undertaken in 2007 is also summarised.

1.2 Background Information

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C has been progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. At the time of the reptile surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1). The boundary of the SSA was therefore used to define the area for the 2009 reptile surveys (which effectively updated and superseded the 2007 and 2008 surveys).

1.2.2 Site Description

The majority of the land within the SSA is agricultural; comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small, rectangular broad-leaved woodlands are located within the northern part of the SSA and a square block of young broad-leaved plantation has been created in the central part of the area, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA. Two watercourses flow west to east through the SSA (further seasonal ditches also occur) and a further watercourse is present on the southern boundary of the SSA. Three ponds occur within the SSA.

The SSA is adjacent to the Bristol Channel. A low cliff, between 0.2m and 10m in height, forms an escarpment between the land and sea.

The land immediately adjacent to the west SSA is similar in character to that within the western part of the SSA, i.e. it comprises agricultural fields (both arable and improved pasture), which are separated by intact species-poor and species-rich hedgerows. A small number of ponds occur and the upper reaches of the Bum Brook flow through the area.

The land east of the SSA is different in character to that within the SSA. It forms part of Bridgwater Bay SSSI and comprises large open fields separated by drains, with very few hedgerows present. The fields immediately adjacent to the SSA have been agriculturally improved and are relatively species-poor. However, those fields to the south and east are less intensively grazed and support a more varied sward and have a greater diversity of plant species.

The proposed development falls into the Vale of Taunton and Quantock Fringes Natural Area[1] (English Nature, 1998), which describes the lowland landscape around the major towns of Taunton, Wellington and Minehead between the Quantock Hills, Brendon Hills, Exmoor and the Blackdown Hills. The Natural Area is characterised by a wide variety of habitats and species, including hedgerow and hedgebanks, calcareous grassland, streams, woodland and scrub, nightingale, otter and bats, all of which occur or could occur within the site.

The Natural Area immediately to the east of the site is the Somerset Levels and Moors Natural Area (English Nature, 1997).

1.3 British Reptiles and their Distribution

There are six native species of reptile in Britain; grass snake (*Natrix natrix*), adder (*Vipera berus*), smooth snake (*Coronella austriaca*), slow worm (*Anguis fragilis*), common lizard (*Zootoca vivipara*) and sand lizard (*Lacerta agilis*). Adder, grass snake, common lizard and slow worm are found throughout Britain, with the latter two species occurring in a wide range of habitats. The adder has more restricted habitat preferences and is therefore less widespread. Grass snake is widespread in England and Wales but absent from most of Scotland. Both sand lizard and smooth snake have very specific habitat requirements and are mainly confined to lowland heathland in Surrey, Hampshire and Dorset.

Adder, grass snake, common lizard and slow worm are the only native reptile species known to occur within Somerset (Beebee & Griffiths, 2000).

[1] The classification of areas of the country into distinct Natural Areas (NAs) was undertaken by English Nature (now Natural England) in order that areas of the countryside identified by unique combinations of physical attributes, wildlife, land use and culture could be grouped together. Overall, 143 NAs, including 24 Coastal NAs have been identified.

2. Methods

2.1 Desk Study

Existing information regarding reptiles within the SSA and surrounding land was obtained from the following sources:

- EDF (which has conducted a wide range of ecological surveys of its land holding and employ a conservation warden at Hinkley to help manage its land and undertake biological recording);
- Somerset Environmental Records Centre (SERC) (who also hold all the records from the Somerset Amphibian and Reptile Group);
- the Environmental Statement (ES) for the Decommissioning of Hinkley A (Magnox, 2006);
- the ES for the proposed West Hinkley Wind Farm (Dulas, 2006); and
- communication with the EDF Conservation Warden, Dick Best and his predecessor Jon Burrell.

Data from SERC was requested in May 2009 (following an initial request in 2007) to ensure that any additional new records submitted in the intervening period were captured. A search area of 3km was used for both searches, although the 2009 data request was based on the larger SSA boundary.

Dick Best provided incidental records of reptiles he encountered during 2007, 2008 and 2009.

2.2 Field Surveys

2.2.1 Survey Area

The extended Phase 1 habitat survey (conducted in March 2007 and updated in 2009) highlighted that the SSA included large areas which were considered unsuitable for reptiles, such as large, open, agricultural fields that provide little cover and restricted foraging opportunities. However, the hedgerow bases (particularly those associated with more mature, dense hedgerows) and the scrub and rough grassland/tall ruderal mosaics (i.e. south of the existing Power Stations) offer more suitable reptile habitat, with foraging and hibernating opportunities, and it is these areas that were targeted for the reptile surveys.

Hence four areas of the SSA were surveyed for the presence of reptiles between 2007 and 2009, as shown in Figure 2. Table 2.1 lists when each area was surveyed and by whom.

Table 2.1 Survey Area Information

Survey Period	Area of SSA Surveyed (refer to Figure 2)				Survey Personnel
	1	2	3	4	
July 2009				✓*	Entec
April - June 2009			✓		Entec
September and October 2008			✓		Entec
September 2008		✓			AMEC
September and October 2007	✓				Entec

* Area 4 overlaps with the southern part of Area 2 (see Figure 2) as additional survey effort was completed during 2009 in the area reptiles had previously been recorded (in 2008)

2.2.2 Reptile Survey Methodology

All the reptile surveys followed guidance provided in Froglife's Advice Sheet 10 – *Reptile Survey, an introduction to planning, conducting and interpreting surveys for snake and lizard conservation* (Froglife, 1999) and took into account additional guidance provided by the *Herpetofauna Workers' Manual* (JNCC, 1998) and *Reptiles: guidelines for developers* (EN, 2004).

Artificial refugia, comprising a range of different sized (minimum of 0.5m x 0.5m) roofing felt tiles, were laid out within the SSA in locations considered to have the highest potential to support reptiles, namely the hedgerow bases, woodland edges and areas of rough grassland. Froglife (1999) suggests placing between 5 and 10 refugia per hectare (ha). However, not all of the habitats within the SSA were considered to provide suitable habitat for reptiles (e.g. the centres of the heavily grazed or arable fields are unlikely to be attractive basking or foraging areas). Therefore, the number of refugia used was altered depending on the proportion of suitable habitat present. For example, following the Froglife guidance would have resulted in between 115 and 230 refugia being placed within Area 1 (Figure 2). Given the predominantly sub-optimal habitat present within this area (i.e. grazed pasture), this was considered to be a disproportionate number of refugia. Therefore, the total number of refugia used in this area was slightly lower. Equally, much of Area 3 provides highly suitable reptile habitat and therefore, slightly more refugia were used than would be recommended following the Froglife guidance. The number of refugia placed in each area is provided in Table 2.2.

The refugia in Areas 1 and 4 were checked on seven different occasions to determine whether reptiles were present or absent in these locations (Froglife, 1999). All the refugia in Area 2 were also checked seven times. The strip of habitat that was found to support reptiles was then subject to a further seven visits to inform an approximate population estimate. Due to the low numbers recorded on the initial seven visits and the presence of only one reptile species, it was considered a further seven visits (rather than 13 to total 20) would be sufficient to characterise the population in this area.

The refugia in Area 3 were checked on 20 different occasions, also to inform a population estimate, as moderate numbers of individuals of several species of reptile were found during the initial visits.

Table 2.2 summarises the approximate size of each area, number of refugia used in each area, the main habitats sampled, the date the refugia were set and the number of visits undertaken. The location of refugia for all Areas is shown on Figure 3.

Table 2.2 Survey Information

Survey Area	Approximate Size of Area	Number of Refugia Used	Habitats Sampled	Date Refugia Set	Number of Survey Visits
1	23ha	100	Hedgerows, woodland edges, long grassland and around scrub*	03 September 2007	7
2	10.2ha	185 (2008) 30 (2009)**	Hedgerows, woodland edges and long grassland	28 August 2008 02 July 2009	7 7
3	10ha	114	Tall ruderal vegetation, short grassland, scrub and woodland edges	02 September 2008	20
4	9.2ha	110	Rough grassland and hedgerow bases	02 July 2009	7

* The locations of the refugia were chosen to avoid stock (which had disturbed refugia initially set).

** Refer to Figure 3 for locations of refugia sampled on 14 occasions

2.3 Survey Limitations

May, April and September are considered to be the best times of the year to survey for reptiles (Froglife, 1999) as the cooler weather encourages the refugia to be used more extensively. Notwithstanding this, the Froglife guidance indicates that surveys for reptiles can be undertaken throughout the summer months as reptiles continue to bask and use refugia. Therefore, whilst most of the surveys were completed during the optimum period, undertaking further surveys outside of this is not considered to have significantly affected the results.

The four areas were surveyed at different times over the period 2007 to 2009. This could potentially limit how the results can be compared between the areas, as reptile populations will fluctuate in size from year to year depending on the availability of prey and suitable basking weather. However, given the small numbers of reptiles recorded and the broadly similar weather conditions experienced through the period this is unlikely to have significantly affected the assessment. Moreover, a benefit to having the survey effort spread over several years is that it may incorporate a mixture of optimal and less favourable years allowing for a better assessment of the whole site.

2.4 Population Classification

The Froglife (1999) guidelines set out a method for obtaining a population class size for reptile species, based on the maximum number of adults recorded on a single survey visit over a period of 20 survey visits. This is also forms part of the criteria for the selection of Key Reptile Sites. Table 2.3 summarises the method used for calculating class size.

Table 2.3 Classification of the Reptile Populations

Species	Low Population (Score 1 point)	Good Population (Score 2 points)	Exceptional Population (Score 3 points)
Common lizard	<5	5-20	>20
Slow worm	<5	5-20	>20
Adder	<5	5-10	>10
Grass snake	<5	5-10	>10

N.B. Figures in the table refer to maximum number of adults seen by observation and/or under tiles (placed at a density of 10 per hectare), by one person in one day.

To qualify for the Key Reptile Site Register a site must meet at least one of the following criteria:

- it supports three or more reptile species;
- it supports two snake species;
- it supports an exceptional population of one species;
- it supports an assemblage of species scoring a total of at least 4 points; or
- the site does not satisfy the above criteria but is of particular regional importance due to local rarity.

This population class assessment is also used to quantify any subsequent mitigation required, such as the recommended duration of any translocation exercises that may be necessary, as detailed by the Herpetofauna Groups of Britain and Ireland (HGBI, 1998). A population class assessment as outlined above was only carried out for Area 3, as the initial survey results indicated that this area could qualify as a Key Reptile Site. The results from the remaining survey areas were used to determine an indicative population class size.

3. Results

3.1 Desk Study

SERC provided several records of reptiles in the vicinity of the SSA. Grass snake has been recorded in Branland Copse (ST207458), between Branland Copse and the Sewage Treatment Works (STW) (ST210456) and offsite at Stolford (ST230459, ~2.5km distant) to the east in

1995 and 1996. Slow worm has been recorded offsite near Stolford in 1996 (ST228458, ~2km away) and to the south around Shurton in 1995 (ST202442, ~1km away);

Reptile surveys were not completed in relation to the West Hinkley Wind Farm ES (which overlaps with the western section part of the SSA) as it was considered that the extent of suitable habitat for reptiles was limited (Dulas, 2006). The ecology surveys in relation to the decommissioning of Hinkley A also did not include reptile surveys as the habitats affected by the works (predominantly hard standing) were not considered suitable for reptiles;

No formal reptile surveys have previously been conducted within the BE landholding, although it is noted (in British Energy [2006]) that the last sighting of grass snake was in 1999. A more recent observation of this species was recorded along the western edge of the SSA boundary at the top of Benhole Lane in 2008 (Stuart Thomas, *Pers. comm.*). A single common lizard was recorded during both the butterfly (Dick Best, *Pers.comm.*) and bird surveys (Stuart Thomas, *Pers. comm.*) to the east of the survey area near the sea front in 2007.

Within the eastern section of the survey area a mature grass snake has been seen in recent years near to Pixies Pond and slow worm are occasionally recorded, most regularly in the area directly south of the Power Station. Common lizard may also occur within the survey area, but there are no confirmed sightings (Dick Best, *Pers. comm.*).

3.2 Field Survey

The presence of two reptile species (slow worm and grass snake) was confirmed within the survey area.

Table 3.1 summarises the maximum counts of adults for each species, within each area (i.e. the highest number of adults recorded on a single survey visit). Juveniles were also detected during these surveys but are not included within this population class assessment, as per Froglife (1999) guidelines. The presence of juveniles does however prove that the populations on site are breeding. A summary of the findings for each day of the surveys in Areas 1, 3 and 4 are presented in Appendix A, with a summary of results from Area 2 presented in Appendix B.

Table 3.1 Maximum Counts of Adults of Each Species in all Compartments

Species	Common Lizard	Slow Worm	Grass Snake
Area 1	0	0	0
Area 2	0	3	0
Area 3	0	9	4
Area 4	0	1*	0

*****This individual was recorded in the part of Area 4 that overlaps with Area 2 (see Figure 2)

Area 1
In Area 1 no reptiles were observed underneath or on top of any refugia placed. Common toads were found using the refugia on two occasions.

Area 2
In Area 2 a maximum count of three slow worms was recorded in 2007, which equates to a density of 0.2 slow worm per hectare. These were all recorded along the south facing side of the hedge adjacent to the track which bisects the site from east to west (Figure 4). This spot is likely to be favoured as the hedge is wide and species-rich, offering refuge and places to hibernate, and supporting an abundance of invertebrate species for slow worm to predate. This side of the hedge also offers good basking potential, as it is south facing and sheltered from the prevailing wind, and as the field is arable it is undisturbed by cattle.

Area 3
In Area 3 a maximum adult count of nine slow worms and four grass snakes were recorded, which equates to a density of 0.9 slow worm and 0.4 grass snake per hectare. Pixies Pond and the western edge of Branland Copse (i.e. adjacent to the road) appeared to be favoured by grass snake. Both these areas include wetter vegetation; which, as grass snakes largely prey on amphibian species, is a preferred foraging habitat. The teasel field at the centre of Area 3 (i.e. between the communication masts), which includes small areas of poorly drained and wet grassland, also supports grass snake and slow worm. In both these areas large numbers of juveniles were recorded suggesting that both species are successfully breeding and that population size maybe increasing.

On two occasion's inconclusive sightings of common lizard in the Pixies Mound field were recorded by surveyors. These are considered inconclusive as on both occasions the surveyor saw, on approaching refugia, a 'quick movement' belonging to what looked like a lizards tail and so could not be confident of their assessment. Given the desk study records the presence of common lizard within the survey area is possible, although based on the results of the targeted reptile surveys completed (and reported here) it is concluded only a very small population of common lizard is likely to occur.

Area 4
In Area 4 a maximum count of one slow worm was recorded in 2009. This was in the same location that slow worm was found in 2008 (i.e. in Area 2, along the south facing side of the hedge adjacent to the track which bisects the site from east to west). As the hedge does not appear to have been regularly managed it is unlikely to have changed significantly since 2008, and remains just as suitable to reptiles, and which is reflected in the similarities between the two surveys results. No other reptiles were recorded in Area 4.

3.3 Population Classification

The population classification, as set out in Froglife (1999), only applies where 20 visits to an area have been completed, which only occurred within the SSA where the initial surveys indicated that a larger population of reptiles could occur, i.e. Area 3. Therefore, as Areas 2 and 4 support only very low reptile numbers, the population classification can only be applied to Area 3. Based on Table 2.3, Area 3 supports a 'good' population of slow worm and a 'low' population of grass snake. Therefore, Area 3 does not qualify as a Key Reptile Site. However, if it is assumed that a very small population of common lizard occur within Area 3, this area alone would then qualify as a Key Reptile Site as it would support three reptile species (common lizard, grass snake and slow worm).

Notwithstanding this, the site does support a low population of both grass snake and slow worm, which are largely concentrated in the Country Wildlife Site located in Area 3, with smaller numbers along woodland edges and hedgerows in the overlap between Areas 2 and 4.

3.4 Habitat Suitability

Due to current management practices Area 3 supports a mosaic of rough grassland, scrub, wetland areas, and woodland, which is currently ideal for foraging, basking and hibernating reptiles.

Areas 2 and 4 support limited habitat favourable to reptiles, restricted to wide-based hedgerows watercourse margins, woodland edges and rough pasture. Whilst these areas are small in extent individually, and unlikely to be sufficiently large enough to support high numbers of reptiles, they are reasonably well-connected into the wider landscape via the hedgerow and ditch network and are therefore accessible to dispersing reptiles.

The habitats present in Area 1 are not considered to be optimal for reptiles as they comprise heavily grazed pasture and regularly managed hedgerows, which are likely to support a poor assemblage of prey species and limited basking and hibernation locations that could be prone to disturbance by cattle.

APPENDIX 20K: HINKLEY INVERTEBRATE SURVEY REPORT

EDF Energy
Hinkley Invertebrate Survey Report

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as 'Hinkley C') on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, with the exception of coastal/marine biodiversity other than birds. This report details the results of invertebrate surveys that were conducted in 2008 and 2009 in order to inform the assessment.

1.2 Background to Development

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, amongst other things, engineering and other design requirements, and environmental information. At the time of the invertebrate surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1). The boundary of the SSA was therefore used to define the area for the 2009 invertebrate surveys (which effectively updated and superseded the 2008 surveys). The SSA boundary includes all of the land within the final 'Construction Boundary'.

1.2.2 Site Description

The SSA comprises open, gently rolling mixed lowland farmland with hedgerows of variable quality, small scrubby[1] woodlands and occasional standard trees. Much of the area is intensively managed, and there is little semi-natural habitat present away from the cliff edge and within the immediate vicinity of the built plant.

A relatively extensive area of land on the southern side, and small areas of ground to the east and west of the built nuclear plant have been subject to management by EDF. This has been

[1] Given their coastal location it is likely that new growth is intermittently 'burnt off' by salt-laden winds. As a result the woodlands are dense and have a low canopy. Woodland only occurs (in terms of the site) within a few hundred metres of the coast.

implemented through a land management plan; initiatives have included the mowing and harrowing of grassland, establishment and management of scrub and the creation of two pools. The result has been the establishment of a range of habitat types including flower-rich grassland (much of which has calcareous influences), woodland, scrub and reedbed.

There are no substantial water-bodies within the SSA, although two streams (Bum Brook and the Holford Stream) that run east-west across the site connect to the Bridgewater Bay SSSI, and Hinkley Point C Drainage Ditch discharges to the intertidal. A more substantial drain (or rhyne) forms the boundary between the site and Wick Moor (North Moor). Standing water is also limited in extent, with the largest pools being to the south of the plant sewage works and in Pixie’s Field.

The eastern boundary of the site is formed (moving north to south) by the operational nuclear plant, the Bridgwater Bay SSSI and mixed farmland which has similar characteristics to that found within the site. This part of the SSSI consists of an area of flat, open improved grassland which is seasonally grazed. To the south and west of the site there is further mixed farmland and a series of small villages including Wick, Shurton and Knighton.

The northern SSA boundary lies adjacent to the Bristol Channel from which it is separated by a low cliff, between 5m and 10m in height that forms an escarpment between the land and sea. At low tide, the shore adjacent to the site comprises a relatively narrow neck of rock (extending to approximately 200m from the cliff and running parallel to it), interspersed with and fringed by muddy sand. Intertidal areas to the west include more extensive areas of mobile sand, while to the east, adjacent to the built nuclear power stations, the intertidal rock platforms, mud and sand extend up to 500m from the upper shore at low water. Further east again, approximately 1km from the proposed build area, the mosaic of intertidal habitats grades into an area of open mud and sand known as Steart Bay.

1.3 Purpose of Survey Work

An aquatic invertebrate survey of watercourses and waterbodies within the SSA was undertaken in May and June 2009. This followed a preliminary aquatic invertebrate survey undertaken in September 2008 (AMEC, 2009) and a walkover survey to identify areas of potential importance to terrestrial invertebrates conducted on 15 August 2008.

The freshwater invertebrate survey took in Hinkley Point C Drainage Ditch, which issues within the coastal fields and discharges to the intertidal, the Holford Stream, Bum Brook (on the southern SSA boundary) and the ditch forming the northern boundary of the Bridgwater Bay SSSI.

The terrestrial invertebrate survey concentrated on the semi-natural area of coombe woodland known as Whitewall Brake (which the surveyor considered to have the most potential invertebrate interest of the woodlands present) and the mosaic of grassland, scrub and woodland habitats immediately south of the existing power station (including the grassland and fringing woody scrub around the plant sewage treatment works).

The 2009 surveys and the August 2008 visit were conducted by Andy Godfrey, an experienced, professional invertebrate ecologist.

2. Methods

2.1 Desk Study

Organisations contacted for contextual data were:

- Natural England;
- Somerset County Council;
- Somerset Environmental Records Centre (SERC); and
- Butterfly Conservation (Bristol & Somerset Branch).

Other sources of information were:

- Hinkley Point Land Management Annual Reviews for the period 1998-2008 (British Energy 1998-2008);
- a list of the fauna and flora recorded from Hinkley Point Nature Trail (Burrell 2006);
- an ecological survey of Hinkley Point' CEGB/NERC Contract ITE Project 945 (Daniels 1986);
- Foster, A. (1986) Hinkley Point, Aquatic Invertebrate Survey. Unpublished survey;
- Drake, C.M. (2003) A survey of the aquatic invertebrates of the Stert Peninsula. Unpublished report to English Nature; and
- a freshwater invertebrate survey of watercourses within the SSA conducted by AMEC in 2008 (AMEC, 2009).

2.2 Field Surveys

2.2.1 Terrestrial Invertebrates

No survey methods were employed on the initial site walkover on 15 August 2008 with the exception of occasional hand searching under reptile mats and the recording of conspicuous invertebrates in the field. The intention of the site walkover was to assess the habitats present throughout the site for invertebrates as a precursor to any requirement for more formal survey work.

In 2009 survey methods concentrated on sweep netting and direct searching. The former involved using a 40cm diameter net mounted on a 1m long angling pole through or around low vegetation as well as the edges of scrub and amongst low tree branches. This method is excellent for sampling a wide selection of active insects and other invertebrates that occur in the ground or scrub layer. Selected target invertebrates were removed using a pooter (aspirator) and preserved in alcohol for later examination. The taxa recorded included Orthoptera (grasshopper and allies), Hemiptera (true-bugs), various Coleoptera families, selected Diptera families

(Tipuloidea, Empidoidea, Syrphidae, Tephritidae, etc.), aculeate Hymenoptera (ants, bees and wasps). Conspicuous species such as butterflies, day-flying moths and adult dragonflies were identified in the field. Some invertebrate taxa had been fairly well recorded in the past particularly moths and butterflies and the present survey concentrated on the less well recorded groups. The direct searching including searching under rocks and reptile mats (for taxa such as molluscs, millipedes, woodlice, ground beetles, etc.), on flower-heads, recording plant galls and leaf-mines, etc.

2.2.2 Aquatic Invertebrates

All the watercourses within the SSA were sampled with a standard pond net[2] during both May and June 2009. The method was as follows:

- Each location selected was surveyed for a three minute period by passing the net along the banks and over the beds of the shallower ditches;
- The contents of the net were washed and sieved on the bank (this involved placing the sample in a 1cm coarse sieve, with a 500 micron sieve and then a bowl beneath it);
- After several decantings, the contents of the 1cm sieve were checked for large freshwater invertebrates and if there were none or once these had been noted, the coarse fraction was returned to the watercourse, whilst the finer fraction was placed in a pot for later examination in the lab;
- The samples were preserved in 10% formalin;
- Once in the lab, each bulk sample was divided up into small parts and these were placed in gridded petri-dishes to which water was added. The petri-dishes were then examined under a binocular stereo-microscope and invertebrates were identified and counted;
- A number of physical and chemical measurements were made on site including pH, conductivity and water temperature using a Hanna HI 98129 handheld meter.

3. Results

3.1 Desk Study

A summary of invertebrate information from all available sources is included below.

[2] 1mm mesh bag, net supplied by EFE/GB Nets Ltd, Totnes.

3.1.1 Annual Land Management Reviews

The Annual Reviews focus on habitat management work undertaken during the year and the results of wildlife monitoring by the site warden and contractors. Butterfly monitoring is conducted each year, and a complete set of annual data are available going back into the early 1990s. Moth-recording has been undertaken on an *ad hoc* basis, glow-worms (*Lampyris noctiluca*) appear to be noted in the report if recorded, while records of other invertebrates are largely incidental.

The more notable invertebrate records from the Annual Reviews are summarised below:

- 1998-1999: Glow-worms are mentioned as occurring in scrub between Pixies Mound and the sub-stations[3];
- 1999-2000: Chalkhill blue (*Polyommatus coridon*) and five other invertebrates are mentioned as new to the site;
- 2000-2001: Grassland management for the marbled white population is mentioned;
- 2001-2002: Butterfly transect results for the years 1996-2001 are provided: 29 species had been recorded at this stage, the most significant of which were dingy skipper (*Erynnis tages*)[4] (low numbers in all years), chalkhill blue in 1999, dark green fritillary (*Argynnis aglaja*) (1996, 1998-2000) and silver-washed fritillary (*Argynnis paphia*) in 1997. Thirteen moth species are also mentioned as new to the site, two of which are UK BAP species, namely the powdered quaker (*Orthosia gracilis*) and the dusky brocade (*Apamea remissa*);
- 2002-2003: Butterfly transect results for 1996-2002 are given. Five moths new to the site are mentioned, and the total number of moth species known from the site is stated to be 184. Habitat management for glow-worm and marbled white are mentioned;
- 2003-2004: Butterfly transect results for the period 1996-2003 are presented and a total of 30 species are listed, with grizzled skipper (*Pyrgus malvae*) being recorded for the first time since 1993. Five moth species new to the site are mentioned, two of which are UK BAP species[5]. Information on glow-worm counts is given;
- 2004-2005: Butterfly transect records for the period 1996-2004 are provided; green hairstreak (*Callophrys rubi*) was recorded for the first time in 11 years in 2004. Golden-ringed dragonfly (*Cordulegaster boltoni*) was recorded for the first time (the total number of dragonfly species recorded from the site stood at 15 when the report was issued). Eight moths were recorded for the first time, one of which, the sallow (*Xanthia icteritia*) is a UK BAP species. The total moth list stood at 199;
- 2005-2006: Butterfly transect records for the period 1996-2005 are provided. Observations on brown argus (*Aricia agrestis*) and its foodplants at Hinkley are given. Two moth species are mentioned as new to the site;

---

[3] This is a county or local BAP species in many English counties or vice-counties, but not in Somerset.

[4] The population has since 'petered out' (John Burrell, pers comm, 2009).

[5] These are the spinach (*Eulithis mellinata*) and garden dart (*Euxoa nigricans*).

- 2006-2007: Further observations on the brown argus at Hinkley Point are provided. Butterfly transect records for the period 1996-2005 are provided. Grayling (*Hipparchia semele*) was recorded for the first time in 2006. Fifteen moth species new to the site are mentioned. Comments on the glow-worm colony are also provided;

- 2007-2008: The report states that up to 20 butterfly species were seen in 2007. The 2007 results are compared with data for the years 2003-2006. Three common day-flying moth species were also recorded.

3.1.2 Hinkley Power Station Nature Trail (Burrell 2006)

This is list of the recorded fauna and flora on the Nature Trail[6] at Hinkley Point compiled by the former warden John Burrell. The lists contain mainly common and widespread invertebrates but some uncommon species are noted:

- The orange ladybird (*Halyzia* 16-*punctata*) was formerly of Notable status in Hyman (1986) but was downgraded by (Hyman & Parsons (1992)[7];

- The UK Biodiversity Action Plan moss carder bee (*Bombus muscorum*) is listed in the report without further detail. Like other declining bumblebee species this species is associated with large areas of open, flower-rich grassland and it has a predominantly coastal distribution in England and Wales (although it occurs in extensive moorland in north-east England and in Scotland (Edwards 2005));

- A total list of moths for the Nature Trail is provided and this includes 25 UK Biodiversity Action Plan species. A list of these species along with the larval foodplants and preferred habitats is provided in Table 1 in Appendix A.

3.1.3 An Ecological Survey of Hinkley Point (Daniels, 1986)

This report provides details of ecological work undertaken in summer 1985 by the Institute of Terrestrial Ecology (ITE). A range of ecological survey was conducted including a butterfly survey and an aquatic invertebrate survey.

The ITE aquatic invertebrate survey involved taking samples from twelve sites on one day (20 June 1985). The results of a survey undertaken by Andy Foster (Nature Conservancy Council) on 16 July 1986 (discussed further in section 3.1.4) were included in this report for comparison: the 1985 survey recorded eighteen taxa from a single ditch sample. It appears reasonable to conclude on this basis that the 1986 survey commented on below was of higher quality than that conducted in 1985.

Key points following a review of data from the ITE survey are as follows:

- Twenty-three butterfly species were recorded from fourteen sampling areas. The most significant species recorded was marsh fritillary (*Eurodryas aurina*) noted

---

[6] The Nature Trail starts in Branland Copse and follows a short route through the woodland, scrub and grassland habitats present to the south of the existing Hinkley A and B Power Stations.

[7] It was formerly scarcer and is one of those species that has presumably spread as a result of climate change.

during the ornithological survey. The location and number of individuals is unclear, and the species does not appear to have been recorded on or near the SSA since;

- There appear to be a number of erroneous records such as the whirlpool ram's-horn snail (*Anisus vorticulatus*) which is a rare species mainly known from East Anglia and a few sites in south-east England. The doubtful record of yellow-veined darter (*Sympetrum flaveolum*) is also likely to be incorrect, since it appears to be based on the nymphal stage and this had not convincingly been recorded in Britain at this time (the species has only regularly started breeding in Britain in recent years). The record of small red damselfly (*Ceriagrion tenellum*) may also be questionable, since this species is associated with bog pools and there are no records for the North Somerset coast (Merritt *et al*, 1996). Additionally, no special comment is made in the text with regard to these species or with regard to the record of the shining ram's-horn snail (*Segmentina nitida*), which is a provisional Red Data Book 2 and a UK BAP species;

- None of these questionable species were recorded on the extensive and relatively recent aquatic invertebrate survey of the Steart Peninsula conducted by Drake in 2003.

3.1.4 Aquatic Invertebrate Surveys

Further results of aquatic invertebrate surveys initially mentioned in the previous section are summarised below. One comprised a single day of survey on Wick Moor (Foster, 1986) and the second was a far more detailed survey of the whole Steart Peninsula (Drake, 2003).

- The survey conducted by Foster (ibid) covered six sample sites. One Red Data Book water beetle *(Haliplus mucronatus)* and three Nationally Scarce water beetle species were recorded. Two ‘Notable’ species *(Coccidula rufa* and *Oplodonta viridula)* recorded during the survey have since been downgraded in status;

- Drake (2003) sampled ten sites on Wick Moor (sample sites 91-100 in the report) and around Stolford with another 90 spread out further east as far as Steart. From the 10 sample sites on Wick Moor and around Stolford, Drake (ibid) recorded one RDB2 soldierfly *(Odontomyia ornata)* and 11 Nationally Scarce species (*Helochares lividus* has recently been downgraded from Notable).

A survey of several water-bodies (eight sample sites) within the SSA was conducted by AMEC on 10 September 2008. Sampling was limited to one-minute per sample[8] and recorded 31 taxa. The main findings were:

- invertebrate communities largely consisted of common and widespread species with no rarities present;

- invertebrate diversity was low at all sites;

- invertebrate abundance was low at five sites and moderate at three; and

---

[8] As opposed to the 3 minutes sampling regime used in the Biological Monitoring Working Party (BMWP) methodology and in the subsequent Entec surveys.

- invertebrate communities reflect slightly acidic to circum-neutral, eutrophic conditions with high levels of organic enrichment.

3.1.5 Further Contextual Information

Invertebrate records for Hinkley Point and environs were obtained from SERC in January 2009. Most of the data appear to be from John Burrell, the previous warden at Hinkley Point. These data are provided in Appendices 1-3 and include several UK BAP, Local BAP, Nationally Scarce (= Notable), and County Notable species. A small number of the records are for the Quantocks SSSI and other areas several kilometres from the SSA.

The Bridgwater Bay SSSI citation specifically mentions a number of invertebrate species. The only one of these species to be recorded on the present survey is the hairy dragonfly (*Brachytron pratense*). This is discussed later in this report.

No invertebrates are listed as county BAP species in the West Somerset Biodiversity Action Plan (West Somerset District Council 2008). The UK BAP click beetle *Synaptus filiformis* which is confined in Britain to a short section of the River Parrott near Bridgwater occurs on the eastern part of the town (Duff 1993) and therefore several miles from Hinkley Point.

A list of County Notable invertebrate species for Somerset has been drawn up and is available on the SERC website.

3.2 Field Surveys

A global positioning system (GPS) was used to obtain accurate grid references of sampling locations and species present, and notes were taken of all the habitats within the SSA. Survey locations are shown on Figure 2.

Generally, vouchers of Red Data Book and Nationally Scarce species have been retained and are available to check by third parties (such as national recorders) if this is required. These vouchers will be retained indefinitely by the surveyor.

Red Data Book and Nationally Scarce/Notable species have been identified as such using the published and unpublished reviews such as Falk (1991), Falk & Chandler (2005) and Foster (2004). A definition of Red Data Book and Nationally Scarce/Notable statuses is provided in Appendix B.

3.2.1 Terrestrial Invertebrate Survey

The most notable result of the initial walkover survey conducted in August 2008 was a record of the Nationally Scarce bombardier beetle *Brachinus crepitans*, which was present under a reptile mat in the cliff top grassland.

The terrestrial invertebrate survey in 2009 included Whitewall Brake, as this is the most natural woodland within the SSA as indicated by the semi-natural vegetation, well-defined woodland vegetation structure and presence of mature oaks and other trees[9]. Also included in the 2009

[9] Other woodland was not surveyed as it comprises tightly spaced, species-poor, similar-aged broad-leaved or mixed plantation with little understorey and a general lack of clearings, rides, footpaths, embayments etc.

terrestrial survey was the grassland-scrub-woodland edge mosaic immediately south of the existing power station including the grassland (and more isolated scrub habitats) around the sewage treatment works.

The terrestrial invertebrate survey recorded a total of 149 species (excluding 29 terrestrial species recorded on the aquatic invertebrate survey). These included two Red Data Book species and four Nationally Scarce species.

- The two Red Data Book species were lauxaniid flies belonging to the genus Homoneura, namely *H. limnea* and *H. interstincta*. Both are poorly known and belong to an under-recorded family and may not be as rare as the few records suggest. Both were represented by males and were determined using the distinctive male genitalia. *Homoneura limnea* is currently only known from three sites according to a recent unpublished review (Falk & Ismay *in prep*.) and most of the records are old. Most *Homoneura* species are associated with isolated scrub or the edges of scrub often in open habitats although this may not be immediately apparent from the information provided in Appendix C;
- Of the Nationally Scarce species, the cranefly *Atypophthalmus inusta* is a damp woodland and carr species and the snail-killing fly *Tetanocera punctifrons* is associated with wetlands, damp woodland, riverside situations, damp heathland and coastal marshes. The picture-winged fly *Acanthiophilus helianthi* is typically found on dry grassland where the larvae feed on common knapweed and other composites whilst *Dioxyna bidentis* has been found on dunes, marshes and other wet areas where its larval foodplant *Bidens tripartita* occurs although there is evidence that it uses a wider range of composite hosts than previously thought. Further details of the ecology, status and distribution of these species are provided in Appendix C whilst the precise locations of these species at Hinkley are summarised in Table 2 in Appendix A;
- *Orthoceratium lacustre* was given Notable status in Falk (1991) but downgraded by Falk & Crossley (2006). Similarly, the orange ladybird, *Halyzia* 16-*guttata* was given Notable status by Hyman (1986) but downgraded by Hyman & Parsons (1992). *Minettia tabidiventris* was introduced as a new name to the British fauna by Merz (2004). The latticed heath *Chiasmia clathrata* is a UK Biodiversity Action Plan species and was already recorded from the Nature Trail (Burrell 2006).

3.2.2 Aquatic Invertebrate Survey (May and June 2009)

Sampling was initially undertaken on 27 May 2009. The intention was to sample the same sample locations surveyed by AMEC (2009). Several of the sample sites surveyed by AMEC (2009) were dry including all of the ponds, and only five samples could be taken to the north of the east-west Green Lane (track) that runs through the centre of the SSA. Details of the taxa recorded are provided in Appendix D whilst details of the sample sites are provided in Appendix E (notes on some of the dry sites were taken and these have been added to Appendix E). The survey on 27 May 2009 also involved sampling the Holford Stream which is located immediately south of the Green Lane. Three samples were taken from this watercourse.

Further sampling was undertaken on 19 June 2009 on the Bum Brook, north of the village of Shurton, (two samples) and on a rhyne separating the existing power station from Wick Moor (three samples). In total thirteen three minute samples were taken by sweeping from the bank or within the watercourse, but slow flow prevented kick sampling.

A total of 152 taxa were recorded, a relatively large proportion of which were in the larval or pupal stage. In addition, two fish, one amphibian and 29 terrestrial invertebrates were caught in the pond net and details of these have been entered into the table in Appendix D.

Two Nationally Scarce species were recorded: the hairy dragonfly (*Brachytron pratense*) and the reed beetle *Donacia clavipes*. The anthomzid fly, *Anagnota bicolor*, caught in one of the pond net samples, is also Nationally Scarce. Details of the ecology, status and distribution of these Nationally Scarce species are provided in Appendix F whilst the precise locations of these species at Hinkley is summarised in Table 2.

Species richness and diversity was generally low in the SSA, confirming the findings of AMEC (2009), although the Holford Stream was generally richer and more faunistically similar to the Wick Moor rhyne than other water courses surveyed. The Bum Brooke has mostly common and widespread running-water taxa in the upstream sample, with taxa more characteristic of slow or still water in the downstream sample, which was taken near the 'ponded-up' ford. The Wick Moor rhyne was relatively rich in taxa but disappointing in that more rare or uncommon species might have been expected from an SSSI.

Some taxa could not be identified to species due to taxonomic uncertainty (such as the *Hydra* species) whilst the identification of nymphs and larvae have generally been left at family level. *Sericostoma schneideri* is used in the sense of Again (2003). It is difficult to differentiate from *Sericostoma personatum* and specimens of this species from other sites, collected by the surveyor, are currently with Professor Rudiger Wagner in Germany awaiting confirmation. The small red-eyed damselfly *Erythromma viridulum* was first found in Britain in 1999 when it was found in Essex (Cham, 2001). Since then, this species has spread rapidly throughout Britain and it is probably present throughout much of England now as far north as Yorkshire. The ephydrid fly *Notiphila graecula* is mentioned as British by Drake (2001).

Appendix A
Hinkley Moths Records

Table A1 UK Biodiversity Action Plan Moths Recorded from Hinkley Point Nature Trail with Details of their Foodplants and Habitats

UK BAP Moth	Larval Foodplants	Habitat
Malacosoma neustria	Trees and shrubs including hawthorn, blackthorn, sallow and fruit trees.	Open, sunny habitats especially hedgerows, scrubby places, gardens, etc.
Hemistola chrysoprasaria	Traveller's-joy	Downland, hedgerows and woodland rides.
Scotopteryx chenopodiata	Vetches and clovers	Wide range including dunes, downland, waste ground and grassy embankments.
Eulithis mellinata	Red currant and black currant	Commons and open woodland
Chiasmia clathrata	Lucerne, clover and trefoil	Downland, embankments, heaths, commons, open woodland and waste ground.
Ennomos fuscantaria	Ash	Woodland and parkland
Diloba caeruleocephala	Hawthorn, blackthorn, apple and other fruit trees	Woodland, commons and hedgerows.
Tyria jacobaeae	Common ragwort, groundsel and other Senecio spp	Especially well-drained, rabbit grazed grassland, also dunes and heaths.
Arctia caja	Wide variety of wild and garden plants	Wide range of open habitats including gardens, damp meadows, fens, river banks, dunes and open woodland.
Spilosoma lubricipeda	Various wild and garden plants	Most rural and urban habitats including gardens, hedgerows, grassland, etc
Spilosoma luteum	Various wild and garden plants	Most rural and urban habitats including gardens, hedgerows, parks and woodland, etc
Euxoa nigricans	Variety of wild and garden plants, trees and shrubs.	Commons, waste ground, gardens, dunes, marshes, etc
Diarsia rubi	Wide variety of herbaceous plants	Most abundant in damp woodland and other marshy places.
Mythimna comma	Cock's-foot and other grasses	Most numerous in fens and marshes, also in grassy places.
Allophyes oxyacanthae	Blackthorn, hawthorn, birch, sallow, apple and rowan	Woodland, hedgerows and bushy places.
Agrochola lychnidis	Various low plants	Wide variety of habitats
Xanthia icteritia	Sallow catkins then the leaves or low plants	Damp woodland, commons, marshy places, heaths, moorland, etc.

Table A1 (continued) **UK Biodiversity Action Plan Moths Recorded from Hinkley Point Nature Trail with Details of their Foodplants and Habitats**

UK BAP Moth	Larval Foodplants	Habitat
Atethmia centrago	Ash (buds then the leaves)	Woodland, hedgerows, river banks, etc.
Acronicta psi	Birch, oak, lime, elm, rowan, hawthorn, blackthorn, etc	Woodland, commons, gardens, heathlands, etc.
Acronicta rumicis	Variety of plants including plantains, docks, bramble, thistles, hop, etc	Most open habitats including gardens, grassland, heaths, wetlands, etc.
Amphipyra tragopoginis	Wide variety of wild and garden plants	Woodland, fens, dunes, moorland, gardens, etc.
Mesoligia literosa	Various grasses	Dunes, chalk sea-cliffs, commons, waste ground, etc.
Hydraecia micacea	Variety of low plants	Sea-cliffs, marshes, waste ground, etc.
Caradrina morpheus	Nettle, dandelion and other low plants	Wide variety of lowland habitats
Hoplodrina blanda	Variety of low plants such as plantain and docks	Gardens, waste ground, dunes, heaths, downland, etc

Table A2 **Occurrence throughout the Hinkley Sample Sites of Red Data Book and Nationally Scarce Invertebrates Recorded In 2009**

RDB & NS Species	Where Recorded in 2009
Homoneura limnea	Habitat mosaic immediately south of power station
Homoneura interstincta	Habitat mosaic immediately south of power station
Brachytron pratense	Wick Moor 4
Donacia clavipes	Wick Moor 5
Atypophthalmus inusta	Whitewall Brake and habitat mosaic immediately south of power station
Acanthiophilus helianthi	Grassland surrounding sewage treatment works
Dioxyna bidentis	Habitat mosaic immediately south of power station
Tetanocera punctifrons	Whitewall Brake
Anagnota bicolor	Wick Moor 4

Table A3 Invertebrate Importance of the Areas Surveyed on the Strategic Site Area

Area Surveyed	Valuation	Rationale
SSA streams north of the Green Lane	Parish	One Regionally Important water beetle. Low aquatic invertebrate species richness and diversity.
SSA ditch south of Green Lane (= Holford Stream)	Parish	No rare or uncommon aquatic species. Low aquatic invertebrate species richness and diversity but better than the streams north of the Green Lane.
Bum Brook	Parish	No rare or uncommon aquatic species. Low aquatic invertebrate species richness and diversity
Wick Moor rhyne	District	Three Nationally Scarce invertebrates suggests local/district interest. More species-rich and diverse than the other watercourses sampled.
Whitewall Brake	District	Two Nationally Scarce species suggests local/district interest. Mature trees and semi-natural woodland vegetation suggest more interest than plantations elsewhere on SSA.
Grassland-scrub-woodland mosaic immediately south of existing power station	District	Two RDB and three NS species suggests local/district interest (RDB species are under-recorded and probably more widespread).

Appendix B
Invertebrate Status Categories

[This document is reproduced from an English Nature document. Full details of the references given are given in the original document].

For the purposes of evaluating invertebrate faunas and priorities for conservation action, invertebrates are attributed various rarity status categories, the meanings of which are given below. Criteria for the selection of species into Red Data Book categories 1 to 5 follow Shirt (1987), with minor modifications derived from Hyman & Parsons (1992) and Parsons (1993).

Categories RDBI (Indeterminate) and RDBK (Insufficiently Known) are based on the criteria used by Wells, Pyle and Collins (1983). Criteria for the selection of Nationally Scarce species follow Eversham (1983) and Ball (1986).

Red Data Book Category 1 RDB1 - ENDANGERED

Definition	Taxa in danger of extinction in Great Britain and whose survival is unlikely if the causal factors continue operating.
	Included are taxa whose numbers have been reduced to a critical level or whose habitats have been so dramatically reduced that they are deemed to be in immediate danger of extinction. Also included are some taxa that are possibly extinct.
Criteria	Species, which are known or believed, to occur as only a single population within one 10km square of the National Grid.
	Species, which only occur in habitats known to be especially vulnerable.
	Species, which have shown a rapid and continuous decline over the last twenty years and are now estimated to exist in five or fewer 10km squares.
	Species which are possibly extinct but have been recorded this century but which if rediscovered would need protection.

Red Data Book Category 2 RDB2 - VULNERABLE

Definition	Taxa believed likely to move into the Endangered category in the near future if the causal factors continue operating.
	Included are taxa of which most or all of the populations are decreasing because of over-exploitation, extensive destruction of habitat or other environmental disturbance; taxa with populations that have been seriously depleted and whose ultimate security is not yet assured; and taxa with populations that are still abundant but are under threat from serious adverse factors throughout their range.
Criteria.	Species declining throughout their range.
	Species in vulnerable habitats.

Red Data Book Category 3 **RDB3 - RARE**

Definition	Taxa with small populations in Great Britain that are not at present Endangered or Vulnerable, but are at risk. These taxa are usually localized within restricted geographical areas or habitats or are thinly scattered over a more extensive range.
Criteria	Species, which are estimated to exist in only 15 or fewer 10km, squares. This criterion may be relaxed where populations are likely to exist in over 15 10km squares but occupy small areas of especially vulnerable habitat.

Red Data Book Category 4 **RDB4 - OUT OF DANGER**

Definition	Taxa formerly meeting the criteria of one of the aforementioned categories but which are now considered relatively secure because effective conservation measures have been taken or the previous threat to their survival in Great Britain has been removed.

Red Data Book Category 5 **RDB5 - ENDEMIC**

Definition	Taxa, which are not known to occur naturally outside Great Britain. Taxa within this category may also be in any of the other RDB categories or not threatened at all. There are few truly endemic species in Great Britain. Most that have been identified are in fairly obscure groups, which are relatively poorly known, and the species may well eventually be discovered elsewhere in Europe.

Red Data Book Appendix **RDBApp. - EXTINCT**

Definition	Taxa which formerly had breeding populations in Great Britain but which are now believed to have died out. (Taxa not recorded since 1900)

Red Data Book Category I **RDB I - INDETERMINATE**

Definition	Taxa considered being Endangered, Vulnerable or Rare, but where there is not enough information to say which of the three categories (RDB1 to 3) is appropriate.

Red Data Book Category K **RDBK - INSUFFICIENTLY KNOWN**

Definition	Taxa that are suspected, but not definitely known, to belong to any of the aforementioned categories, because of lack of information.
Criteria	Taxa recently discovered or recognised in Great Britain, which may prove to be more widespread in the future (although some recent discoveries may be placed in other categories if the group to which they belong is thought not to be under- recorded).
	Taxa with very few or perhaps only a single known locality but which belong to poorly recorded or taxonomically difficult or unstable groups.
	Species with very few or perhaps only a single known locality, inhabiting inaccessible or infrequently sampled but widespread habitats, such as some northern moorland species, species associated with some agricultural situations and species which are adult only during the winter.
	Species with very few or perhaps only a single known locality and of questionable native status, but not clearly falling into the category of recent colonist, vagrant or introduction.

Provisional Red Data Book **pRDB**

Definition	The prefix ‘p’ before any Red Data Book category implies that the grading is provisional. In the majority of cases this means that the species' status has been reconsidered and changed in a Species Group Review produced subsequent to the publication of the relevant Red Data Book.
	The statuses so given are described as provisional, pending the publication of a future edition of that Red Data Book. These statuses are however, based upon a greater amount of evidence than was available for the original Red Data Book and therefore are more likely to be a true representation of the species' actual status.
	The prefix ‘p’ is also used for RDB status categories in groups where a Red Data Book has not yet been produced but is in preparation, or is used for species in groups covered by the original Red Data Book, where it is considered that there is evidence that the original grading was incorrect or that there has been a genuine change in status of the taxon.

Nationally Scarce (Notable) Species

The term ‘Nationally Scarce‘ was adopted and replaced the term ‘Notable‘ during the compilation of the Guidelines for the Selection of Biological SSSIs. The two terms are thus interchangeable but ‘Nationally Scarce’ is preferable.

Ball (1986) discusses the allocation of species to Nationally Scarce categories:

‘’The Invertebrate Site Register project includes the preparation of National Species Reviews which seek to identify and document uncommon species. The criteria used have been based directly on those evolved by botanists and two levels of 'National Notability’ has been used. These are Notable A, for species known to occur in 30 or less 10km squares of the National Grid and Notable B for those known from 100 or less squares.

Although this system can be used directly with well-recorded groups like Dragonflies, Butterflies and Grasshoppers; when dealing with many other groups of insects, the level of recording is not sufficient to apply the criteria rigorously. A combination of three alternative approaches has been employed:

1. *The approximate number of squares in which a species may occur can be estimated by looking at the number it has been recorded from as a proportion of the total in which the whole group (e.g. its family) has been recorded.*

Coarser measurements such as the number of vice-counties in which a species has occurred can be used (7 or less for Notable A, 20 or less for Notable B).

2. *Experts can be asked to use their field experience to judge the status of species in their particular specialist group against others with a better-established status. By consulting as many people as possible and taking a consensus of their views, geographical and personal biases can be minimized.*

3. *In some groups in which widespread interest and recording is a rather recent phenomenon, no attempt has yet been made to separate Notable A and Notable B species, and all Nationally Notable species are simply graded 'Notable'.*

Nationally Scarce (Notable) N - NOTABLE

Definition.	Species, which are estimated to occur in 16 to 100 10km, squares in Great Britain. The subdividing of this category into Nationally Scarce A and Nationally Scarce B has not been attempted for some species because of either the degree of recording that has been carried out in the group to which the species belongs, or because there is some other reason why it is not sensible to be so exact.

Nationally Scarce (Notable) Category A Na - NOTABLE A

Definition	Taxa which do not fall within RDB categories but which are uncommon in Great Britain and thought to occur in 30 or fewer 10km squares of the National Grid or, for less well recorded groups, within 7 or fewer vice-counties.

Nationally Scarce (Notable) Category B Nb - NOTABLE B

Definition	Taxa which do not fall within RDB categories but which are uncommon in Great Britain and thought to occur in between 31 and 100 10km squares of the National Grid or, for less well recorded groups, between 8 and 20 vice-counties.

Regionally Scarce (Notable) Nr - NOTABLE

Definition	Species which are considered to occur in 5 or less 10km squares in an area equivalent in size to a region of the old Nature Conservancy Council or larger, approximately one eighth the total area of England. Such statuses were worked out during the compilation of the Invertebrate Site Registers. They cover various groups in Scotland, in northern England as a whole, in north-east and north-west England, in vice-county Yorkshire and in the east Midlands and East Anglia. They were worked out by local entomologists.

LOCAL

Definition	The term is not rigidly defined, but loosely means species confined to a particular habitat type (usually associated with better quality examples of that habitat), a particular geographic area, or species that are too widespread to warrant Nationally Scarce (Notable) status but are nevertheless infrequently encountered.

COMMON

Definition	Common or very widespread species, frequently recorded.

SYANTHROPIC SPECIES

Definition	Species dependent upon man, his buildings, livestock or crops.

UNKNOWN

Definition	Species where no status has been attributed. There may be confusion over the species' taxonomy, it may belong to a poorly recorded group or may occur in an infrequently sampled habitat. As a species is entered into the Invertebrate Site Register or RECORDER, the status automatically defaults to 'Unknown'. Certain common or local species may therefore occasionally appear in this category if there has been no necessity to use the species record.

Appendix F
Details of the Ecology, Status and Distribution of the Red Data Book and Nationally Scarce Species Recorded

Red Data Book 2

Homoneura limnea

Falk & Ismay (in prep.) state that this species has only been recorded from three UK sites, namely, the Monnow Valley, Herefordshire (between 1907 and 1912); Merthyr Mawr Warren, South Wales (1992), Pyle (1908) and nearby Porthcawl (1906), Glamorganshire. There is no recent information on this species in Britain. It may persist at sites in Glamorganshire such as Kenfig Burrows NNR (which may encompass the Pyle and Porthcawl sites), although there has been some degrading of the coast through construction of steel works and recreational facilities. The Glamorganshire sites are essentially coastal dunes and the River Monnow has numerous sandy banks, suggesting a link with sandy areas. The early stages of this species are unknown; larvae of this family are believed to develop in decaying vegetable matter including fallen leaves.

Red Data Book 3

Homoneura interstincta

This species has been recorded widely in southern England (nine counties) with an isolated record for North Wales (Merionethshire). There are seven known post-1960 records according to Falk and Ismay (in prep.). It is probably more widespread but belongs to an under-recorded family. Most records refer to damp broad-leaved woodland, a few refer to wetlands, possibly in shaded situations or associated woods and a record for Thompson Common, Norfolk refers to an area with pingo pools, possibly in association with carr. The early stages of this species are unknown; larvae of this family are believed to develop in decaying vegetable matter including fallen leaves.

Nationally Scarce

Brachytron pratense

The hairy dragonfly is most commonly found in Britain on the coastal levels and grazing marshes of Somerset, Sussex, Kent and Norfolk. It also occurs in the fens of Anglesey, the Cheshire meres and on the wetlands along the coast of South Wales and Suffolk. This species breeds in mesotrophic ponds, lakes including mature gravel pits, canals, ditches and marshy fens where there is plenty of tall emergent vegetation such as common club-rush, common reed, bulrush and great fen-sedge. This species has a short flight season from mid-May to mid-July. It can be found with other species that favour unpolluted well-vegetated dykes and fens (Merritt et al 1997).

Donacia clavipes

This reed beetle has been recorded from England, Scotland and Wales. It is found in aquatic and semi-aquatic habitats such as freshwater lakes, ponds and ditches. It is usually associated with reed *Phragmites australis* and bur-reed *Sparganium* spp. The adults are typically found on emergent and marginal vegetation and have been recorded in June.

Atypophthalmus inusta

This cranefly occurs as far north as Yorkshire and Wales with records predominating in southern counties. Falk (1991) stated that he knew of 40 post-1960 records; this is likely to have increased quite considerably over the last 20 years. This species is found in damp woodland and carr in lowland areas. The larvae breed in fungi including decaying *Merulius tremellosus*. The adults have been recorded from June to September.

Acanthiophilus helianthi

This picture-winged fly has been recorded from scattered localities in southern England (nine counties) and one county in Wales. Falk (1991) stated that there were about ten post-1960 sites known to him, scattered widely over the known range. It has been found more frequently since (Clemons 1996). This species occurs in dry grassland, meadows and occasionally gardens. The larvae have been reared from the flowerheads of common knapweed (*Centaurea nigra*) in Britain although abroad they are known from around fifty species of Cardueae. The adults have been recorded from June to September.

Dioxyna bidentis

Records for this picture-winged fly are widely dispersed in England as far north as Yorkshire and with an old (1936) record for Scotland. This species is widespread but local with nine known post-1960 records. The habitat preferences of this species are unclear, records include marshes and wet areas on commons and dunes. The larvae usually develop in the flowerheads of the local tripartite bur-marigold *Bidens tripartita* although it may develop in a range of composite hosts according to Clemons (1996). The adults have been recorded from June to October.

Tetanocera punctifrons

Records of this snail-parasitoid fly have been widely scattered in England (nine counties), Wales (two counties) and Scotland (three counties). This species is widespread with about 20 post-1960 sites known to Falk (1991). This species occurs in wetlands, damp woodland, also riverside situations, damp heathland and coastal marshes. The larvae probably develop as predators or parasitoids of gastropod molluscs, but it is unclear whether they attack aquatic or terrestrial species.

Anagnota bicolor

Records for this minute anthomyzid fly are widespread with records from thirteen English counties, four Welsh counties and five Scottish. There are 16 post-1960 records according to Falk and Ismay (in prep.) but it is probably more widespread but too secretive or scarce to be detected by the present levels of recording. This species is usually associated with *Phragmites* in marshes and coastal levels according to Falk and Ismay (in prep.), although most of the surveyors records have come from grass and sedge tussocks. There are records of the larvae developing in the galls of the chloropid fly *Lipara* on *Phragmites*.

APPENDIX 20L: HINKLEY INVERTEBRATE SURVEY REPORT – COASTAL INVERTEBRATE SURVEY

Coastal Invertebrate Survey 2010

June 2011

CONTENTS

[This page is intentionally left blank.]

1 INTRODUCTION

1.1.1 During the Hinkley Point C (HPC) Project Stage 2 consultation in 2010, Somerset County Council commented that a number of notable invertebrate species had been recorded in coastal habitats on the north side of the Severn Estuary in Gwent and Glamorgan. In view of this, they suggested that there may be potential for notable invertebrates to occur in the coastal habitats within and/or adjacent to the HPC site boundary.

1.1.2 In response to the County Council's concerns, a survey was undertaken to assess the potential for notable invertebrate populations to occur in the coastal habitats adjacent to the HPC site. This survey was undertaken by an experienced entomologist (Andy Godfrey) and augmented previous invertebrate survey work that he had undertaken in relation to habitats elsewhere on the HPC site.

2 METHODS

2.1 Survey Area

2.1.1 The survey area comprised a 1km stretch of coastline west of the existing Hinkley Point Power Station Complex. This included the entire length of coastal habitats adjacent to the HPC site.

2.2 Habitat Assessment

2.2.1 The main purpose of the survey was to identify whether there are any habitats along the coastal strip that are likely to support important populations of invertebrates. Information was collected about vegetation cover, and about habitat features that could support important populations of invertebrates, including recently slumped areas of cliff with 'soft' areas of bare ground, seepage and other wetland areas.

2.3 Sampling Methods

2.3.1 To supplement the habitat suitability assessment, the opportunity was taken to collect invertebrate records in order to augment the findings from any future systematic survey work, should this be needed. This involved the use of a suite of standard methods for collecting invertebrates, as described below.

2.3.2 All observations of butterflies, day-flying moths and other conspicuous invertebrates were recorded in the field, without the need for collection. In addition, terrestrial invertebrate samples were collected by both sweep-netting and direct searching (e.g. under stones or timber, on flower-heads) at regular sample points on each transect route.

2.3.3 During the survey of the foreshore, decaying seaweed and other shoreline material was sieved in order to extract any associated invertebrates. All samples were preserved in alcohol for later identification under a microscope (to species-level wherever practical), using standard reference works.

3 RESULTS

3.1 Weather Conditions

3.1.1 The survey work was undertaken on 15 September 2010. The weather conditions were sunny, with 30% cloud cover and a strong south westerly wind.

3.2 Habitats

3.2.1 The habitats present comprise sections of cliff, which, especially in the vicinity of Whitewall Brake, support dense scrub dominated by elder (*Sambucus nigra*), bramble (*Rubus fruticosus agg.*) and blackthorn (*Prunus spinosa*). There are also some areas of bramble combined with tall herb grassland, supporting species that include teasel (*Dipsacus fullonum*), broad-leaved dock (*Rumex obtusifolius*), *Myosotis* sp., false oat-grass (*Arrhenatherum elatius*), hedge woundwort (*Stachys sylvatica*), creeping thistle (*Cirsium arvense*) and cleavers (*Galium aparine*). Where Whitewall Brake adjoins the coastal strip, there is a section of the shoreline where there is no cliff.

3.2.2 Along the shallow section of cliff in the vicinity of Whitewall Brake, no habitats were recorded that are likely to support important populations of invertebrates. Towards the eastern end of the coastal strip and to the west of Whitewall Brake, the cliffs are taller and have extensive exposures of hard rock, often with sparse vegetation. Again no habitats were recorded that are likely to support important populations of invertebrates.

3.2.3 Along the cliff top, habitats include scrub, and short and rank grassland, as well as the semi-natural woodland of Whitewall Brake. To the west of Whitewall Brake, the extent of scrub declines until the semi-natural habitat along the cliff top is restricted to narrow strips of calcareous grassland between the arable crops and cliff edge. The topography here is more uniform than to the east of Whitewall Brake, with few areas that provide a sheltered microclimate for invertebrates.

3.2.4 The foreshore mostly comprises coarse shingle and exposed wave-cut platforms with infrequent drift-lines of seaweed and piles of sea-worn timber, which provide habitat for invertebrates that are adapted to live in this environment.

3.3 Invertebrate records

3.3.1 Fifty three terrestrial invertebrate species were recorded during the survey. These included three Nationally Scarce species. **Table 1** lists these species, their nature conservation status and the location in which they were found. In addition to these three notable species, the Nationally Scarce bombardier beetle *Brachinus crepitans* was recorded on the cliff top during a previous survey (15 August 2008 - Hinkley Invertebrate Survey Report, Entec 2009).

Table 1 – Notable invertebrate species recorded

Scientific name	Common Name	Nature Conservation Status	Location
Platycleis albopunctata	Grey bush-cricket	Nationally Scarce	Cliff top
Cercyon depressus	A scavenger beetle	Nationally Scarce	Foreshore
Heterota plumbea	A rove beetle	Nationally Scarce	Foreshore

3.3.2 A single grey bush-cricket (*Platycleis albopunctata*) was swept from scrub vegetation on the cliff top. This large cricket is strictly a coastal species in Britain and is frequent along the coast of southern England and Wales, occurring amongst coarse grasses and rough vegetation on sand dunes, shingle beaches and sea cliffs.

3.3.3 The scavenger beetle *Cercyon depressus* has been recorded throughout England, Scotland and Wales and is labelled as very local in Somerset, with old records (from the 1950s) from Blue Anchor and Berrow to the west and east of the site respectively (Duff, 1993). It is associated with coastal habitats such as beaches and saltmarsh creeks and is usually found under decaying seaweed and other coastal debris (as it was during this survey).

3.3.4 The rove beetle *Heterota plumbea* has mainly been recorded from southern England and Wales, but is also very local in Somerset (Duff, 1993) and is a Somerset Notable species. It is another coastal species, occurring under seaweed and amongst shingle.

4 CONCLUSIONS

4.1.1 None of the habitats that were recorded along the coastal strip are likely to support important populations of invertebrates. There is therefore no need for systematic invertebrate surveys on this part of the site.

4.1.2 Although the four notable invertebrate species were recorded at only a limited number of locations along the strandline or cliftop, it is likely that these species also occur elsewhere along the coastal strip that adjoins the site of the proposed development. Thus there is no reason to design the development to avoid the locations where these species were recorded.

APPENDIX 20M: IDENTIFICATION OF BIODIVERSITY RECEPTORS

Appendix 20M - Identification of Biodiversity Receptors

Box 20M.1 Designated Wildlife Sites, and Priority Habitats and Species

Statutory Nature Conservation Sites

- Special Areas of Conservation (SACs) and candidate SACs.
- Special Protection Areas (SPAs) and proposed SPAs.
- Sites of Community Importance.
- Ramsar sites.
- European offshore marine sites.
- Sites of Special Scientific Interest (SSSIs).
- National Nature Reserves (NNRs).
- Local Nature Reserves (LNRs).

Non-statutory Nature Conservation Sites

Non-statutory nature conservation sites in Somerset are notified as County Wildlife Sites.

Priority Habitats and Species

- Populations of species or areas of habitat for which European sites are designated.
- Populations of birds meeting the threshold for European importance (1% of the relevant international population).
- Species listed as Near Threatened, Vulnerable or Endangered in the UK on the IUCN Red Data List (http://www.iucnredlist.org/apps/redlist/search).
- Habitats and species of principal importance for the conservation of biological diversity in England. These are listed on http://www.ukbap-reporting.org.uk/news/details.asp?X=45. These include those UK BAP priority habitats and species that occur in England.
- Species listed as being of conservation concern in the relevant UK Red Data Book (RDB) or the Birds of Conservation Concern Red List.
- Nationally Rare and Nationally Scarce species, which are species recorded from, respectively, 1-15 and 16-100 10x10km squares of the national grid;
- Populations of birds comprising at least 1% of the relevant British breeding/wintering population (where data is available).
- Ancient woodland (i.e. areas that have been under continuous woodland cover since at least 1600).
- Habitats and species listed in the Somerset LBAP.
- Species listed in County Red Data Books or other county lists of rare or declining species.
- Populations of birds comprising at least 1% of the relevant County breeding/wintering population (where data are available).
- Habitats and species listed in the West Somerset LBAP.
- Habitat networks.

Box 20M.2 Legally Protected and Controlled Species

Legal Protection

Many species of animal and plant receive some degree of legal protection. For the purposes of this ES, legal protection refers to:

- species included on Schedules 1, 5 and 8 of the *Wildlife and Countryside Act 1981* (as amended), excluding species that are only protected in relation to their sale (see Section 9[5] and 13[2]), reflecting the fact that the Scheme does not include any proposals relating to the sale of species;
- species included on Schedules 2 and 5 of the *Habitats Regulations 2010*; and
- badgers, which are protected under the *Protection of Badgers Act 1992*.

Legal Control

Schedule 9 of the *Wildlife and Countryside Act 1981* (as amended) lists species of animal that it is an offence to release or allow to escape into the wild and species of plant that it is an offence to plant or otherwise cause to grow in the wild.

APPENDIX 20N: BIODIVERSITY RECEPTOR SCOPING TABLE

Appendix 20N: Biodiversity Receptor Scoping Table

Table 20N.1 – Results of biodiversity receptor scoping – PART 1

'Important' receptors (i.e. that meet the criteria in Appendix 20M) recorded within the study area from both desk study and field surveys	Legally protected and/or could be of sufficient value for potential impacts to be significant?		Justification if receptors are of insufficient value for impacts to be significant	Scoping conclusion
	Legally protected	Value[1]		
Habitats				
Off-site ditches and grazing marsh	Yes	Yes	N/A	See Table 20N.2
Off-site wetland areas	No	Yes	N/A	See Table 20N.2
Lowland calcareous grassland	No	Yes	N/A	See Table 20N.2
Woodland	No	Yes	N/A	See Table 20N.2
Hedgerows	No	Yes	N/A	See Table 20N.2
Watercourses	No	Yes	N/A	See Table 20N.2
Water bodies	No	No	The pond within the site is a heavily shaded and scrub-encroached seasonal waterbody. It does not meet the criteria for the UKBAP 'Ponds' priority habitat.	Scoped out

[1] Value - the receptor is of sufficient quality (for sites and habitats) or size (for sites, habitats or species populations) that an impact upon it could be significant.

'Important' receptors (i.e. that meet the criteria in Appendix 20M) recorded within the study area from both desk study and field surveys	Legally protected and/or could be of sufficient value for potential impacts to be significant?		Justification if receptors are of insufficient value for impacts to be significant	Scoping conclusion
	Legally protected	**Value[1]**		
Habitat networks	No	Yes	N/A	See Table 20N.2
Fauna				
Breeding birds	Yes	Yes	N/A	See Table 20N.2
Lesser whitethroat	Yes	Yes	N/A	See Table 20N.2
Cetti's warbler	Yes	Yes	N/A	See Table 20N.2
Wintering waterbirds (including SPA/Ramsar/SSSI qualifying features)	Yes (in part)	Yes	N/A	See Table 20N.2
Passage waterbirds (including SPA/Ramsar/SSSI qualifying features)	Yes (in part)	Yes	N/A	See Table 20N.2
Wintering and passage birds (other than waterbirds)	No	Yes	N/A	See Table 20N.2
Badger	Yes	No	Badgers are sufficiently common and widespread in Somerset that an impact upon the local population would not be significant	See Table 20N.2 (due to legal requirements)
Barbastelle bat	Yes	Yes	N/A	See Table 20N.2
Lesser horseshoe bat	Yes	Yes	N/A	See Table 20N.2
Greater horseshoe bat	Yes	Yes	N/A	See Table 20N.2
Bat assemblage	Yes	Yes	N/A	See Table 20N.2
Otter	Yes	Yes	N/A	See Table 20N.2

'Important' receptors (i.e. that meet the criteria in Appendix 20M) recorded within the study area from both desk study and field surveys	Legally protected and/or could be of sufficient value for potential impacts to be significant?		Justification if receptors are of insufficient value for impacts to be significant	Scoping conclusion
	Legally protected	Value[1]		
Water vole	Yes	Yes	N/A	See Table 20N.2
Hedgehog	No	No	The limited extent of semi-natural habitats on the site mean that the number of individuals are likely to be present is too small for an impact to be significant	Scoped out
Reptiles	Yes	No	The density at which slow-worm occurs within the site is low (due to the majority of the habitat present being of poor-quality) and slow-worms are common and widespread in Somerset. Therefore, the number of individuals that could be affected is likely to be too small for an impact to be significant.	See Table 20N.2 (due to legal requirements)
Great crested newt	Yes	Yes	N/A	See Table 20N.2
Common toad	No	No	Only a single common toad was recorded at the proposed development site despite regular site visits for both amphibian and reptile surveys. This indicates that the site is unlikely to support a large toad population. Therefore it is unlikely that a significant impact on the local common toad population would occur.	Scoped out
Invertebrate assemblage (including Nationally Scarce, UKBAP and Somerset Notable species)	No	Yes	N/A	See Table 20N.2
Somerset Notable plants (on-site)	No	Yes	N/A	See Table 20N.2
LBAP and Somerset Notable plants (off-site)	No	Yes	N/A	See Table 20N.2
Designated Sites				
Exmoor and Quantocks Oakwoods SAC	Yes	Yes	N/A	See Table 20N.2

‘Important’ receptors (i.e. that meet the criteria in Appendix 20M) recorded within the study area from both desk study and field surveys	Legally protected and/or could be of sufficient value for potential impacts to be significant?		Justification if receptors are of insufficient value for impacts to be significant	Scoping conclusion
	Legally protected	Value[1]		
Severn Estuary SPA and Ramsar	Yes	Yes	N/A	See Table 20N.2
Severn Estuary SAC	Yes	Yes	N/A	See Table 20N.2
Bridgwater Bay SSSI	Yes	Yes	N/A	See Table 20N.2
Hinkley CWS	No	Yes	N/A	See Table 20N.2
Claylands Corner CWS	No	Yes	N/A	See Table 20N.2
J24 Embankment CWS	No	Yes	N/A	See Table 20N.2
Other CWSs	No	Yes	N/A	See Table 20N.2

* Where a ZoI is not applicable (N/A) to a receptor, the main reason is given under the column headed ‘ZoI’ using the categories that are listed below. In these instances, the ‘Receptor within ZoI’ column is also not applicable.

N/A 1 The receptor is not sensitive to the environmental change.

N/A 2 The receptor is likely to be of insufficient value for the environmental change to have a significant impact (these receptors are recorded as ‘No’ in the third column of Table 20N.1).

N/A 3 The receptor is located outside of the zone of influence associated with land-take.

APPENDIX 20O: PROTECTED AND NOTABLE SPECIES RECORDS

Appendix 20O
Protected and Notable Species Records

7 Pages

Table 20O.1 Protected and Notable Species Records from SERC within 2km of the Site

Common Name	Latin Name	Rationale for Species Importance	Location			Distance (km) & Direction from Site
			Date of Record	NGR	Site Name	
Amphibians						
Common Toad	*Bufo bufo*	WCA, UKBAP	1995 - 1996	ST207458	Hinkley	0.3 E
Great Crested Newt	*Triturus cristatus*	WCA, EUHD, UKBAP, LBAP	1995	ST210455	Hinkley	0.7 ESE
			1993 - 1996	ST207458	Hinkley	0.3 E
Birds						
Barn Owl	*Tyto alba*	WCA, LBAP	1993 -1995	ST207458	Hinkley	0.3 E
			19-Jun-06	ST197452	Proposed Wind Farm, Hinkley	0.9 SW
Black-tailed Godwit	*Limosa limosa*	WCA	23-Nov-03	ST200457	Proposed Wind Farm, Hinkley	0.4 WSW
			16-Mar-06	ST197452	Proposed Wind Farm, Hinkley	0.9 SW
Bullfinch	*Pyrrhula pyrrhula*	LBAP	1995 - 2005	ST207458	Hinkley	0.3 E
			Mar 06 - Jun 06	ST197452	Proposed Wind Farm, Hinkley	0.9 SW
Common Scoter	*Melanitta nigra*	WCA, EUBD, UKBAP	20-Mar-06	ST197452	Proposed Wind Farm, Hinkley	0.9 SW
Cuckoo	*Cuculus canorus*	UKBAP	1995	ST207458	Hinkley	0.3 E
Curlew	*Numenius arquata*	UKBAP, LBAP	1993 - 1995	ST207458	Hinkley	0.3 E
			OCT 2003 - MAY 2004	ST200457	Proposed Wind Farm, Hinkley	0.4 WSW
			Mar-06	ST197452	Proposed Wind Farm, Hinkley	0.9 SW

Key:

LBAP: Species subject of a Species Action Plan (SAP) or Group SAP in one of the current Local Biodiversity Action Plans (LBAP) in Somerset.

UKBAP: Species listed in the United Kingdom Biodiversity Action Plan (UKBAP)

Habs Regs Sch 2: Species protected under Schedule 2 of the Conservation of Habitats and Species Regulations 2010.

WCA: Species listed under Schedule 1 and Schedule 5 of the Wildlife and Countryside Act 1981 (as amended)

Common Name	Latin Name	Rationale for Species Importance	Location			Distance (km) & Direction from Site
			Date of Record	NGR	Site Name	

BA: Species is protected under the Protection of Badgers Act 1992

NB: Notable bird species or populations determined based on county data and local habitat characteristics

APPENDIX 20P: HIGHWAY IMPROVEMENTS BASELINE INFORMATION

Appendix 20P - Highway Improvements Baseline Information

1 Introduction

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as 'HPC') on land to the west of the existing Hinkley A and B stations. As part of the suite of associated development sites necessary to support the construction of HPC, EDF are proposing a programme of highway improvements (herein referred to as 'schemes') to a number of key junctions located on the main access routes to the HPC site.

This technical note presents the results of the baseline ecological work completed for the schemes, comprising; a desk study and an extended Phase 1 survey. The methodology for the desk study and extended Phase 1 Habitat survey and an assessment of the potential effects of the development proposals, is reported in the accompanying Environmental Statement (EDF, 2011).

2 Results

The results of the desk study completed for each of the highway improvement sites is provided in **Table 2.1.**

The results of the extended Phase 1 Habitat survey completed at each site are provided in **Table 2.2.**

Table 2.1 Desk Study Information for the Highway Improvement Sites

Scheme	Designated Sites with 500m of the Site	Protected and Notable Species Records within 500m of the Site (provided by SERC)
A38 Bristol Road/The Drove	None	There are records of the following species from the area of green urban space and housing directly to the east of the A38 and adjacent to the site. They are: • tawny owl (*Strix aluco*); • kingfisher (*Alcedo atthis*); and • spotted flycatcher (*Muscicapa striata*).
A38 Taunton Road/Broadway	Brownes Pond County Wildlife Site (CWS) is located 300m to the south west of the scheme. It has been designated as it supports legally protected species.	SERC provided records of kingfisher and merlin (*Falco columbarius*) from within 500m of the site (both 380m to the south-east)
A38 Bristol Road/Wylds Road	None	None
Wylds Road/The Drove	None	None
A39 Sandford Corner	None	SERC provided a single record of brown hare (*Lepus europeaus*) from within 500m of the site (320m to the east)
M5 Junction 23 (Including Dunball Roundabout)	South Hills Woods CWS is located 300m to the south-east of the scheme. It is an area of ancient semi-natural broad-leaved woodland and species-rich grassland.	SERC provided records of hen harrier (*Circus cyaneus*) and badger (*Meles meles*) adjacent to the site
Washford Cross Roundabout	Furzy Ground Plantation CWS is an area of semi-natural broad-leaved woodland on a tithe-map woodland site. It is located 500m to the north of the scheme. Puthills Copse CWS is an area of ancient semi-natural broad-leaved woodland. It is located 500m to the west of the scheme.	None
Junction improvements at Clayland Corner	The Claylands Corner Verge CWS is located within the red line boundary of the scheme. This area comprises species-rich unimproved neutral grassland, supporting diverse invertebrate fauna, and flanked by tall hedge/tree-belt and mature scrub.	SERC provided records of the Somerset Notable species slender tare (*Vicia parviflora*) and grass vetchling (*Lathyrus nissolia*) from Claylands Corner CWS.

Scheme	Designated Sites with 500m of the Site	Protected and Notable Species Records within 500m of the Site (provided by SERC)
	Stockland Moor Wood CWS is located 140m to the south-east of the site. It is an area of ancient semi-natural broad-leaved woodland with an area of swamp and carr woodland. New Barn Wood CWS is located 420m to the north east of the site. It is an area of ancient semi-natural broad-leaved woodland.	
C182 Farringdon Hill Lane Horse Crossing	Mud House Copse CWS is located adjacent to the boundary. It is an area of ancient semi-natural broad-leaved woodland. Wick Park Covert CWS is located 180m to the south-east of the scheme. It is an area of ancient semi-natural broad-leaved woodland. Bridgwater Bay SSSI is located 330m to the north of the scheme. The site has been designated for the following habitats and species: • mudflats; • saltmarsh; • shingle beach; • grazing marsh; • internationally and nationally important numbers of wintering and passage wildfowl including (in addition to species cited in other designations) black-tailed godwit (*Limosa limosa*), teal (*Anas crecca*) and grey plover (*Pluvialis squatarola*); • a diverse invertebrate fauna of ponds and ditches; • the ecological link to the Somerset Levels and the position of the area in the context of the Severn Estuary	SERC provided records of merlin, grey partridge (*Perdix perdix*) and nightingale (*Luscinia megarhynchos*) within 500m of the site (between 350 and 450m from the site). Otter (*Lutra lutra*) and brown hare have also been recorded within the study area (both 370m to the north). Greater butterfly orchid (*Platanthera chlorantha*) and bluebell (*Hyacinthoides non-scripta*) have been recorded within Mud House Copse.
Cannington High street	Cannington Brook CWS is located 260m to the south of the scheme. It has been designated for supporting otter.	SERC provided records of common pipistrelle (*Pipistrellus pipistrellus*), otter, grass snake (*Natrix natrix*) and slow-worm (*Anguis fragilis*) from with the study area. Kingfisher, peregrine and spotter flycatcher have also been recorded within 100m of the site.

Scheme	Designated Sites with 500m of the Site	Protected and Notable Species Records within 500m of the Site (provided by SERC)
Huntworth Roundabout	J24 Embankment CWS is located partly within the southern area of the red line boundary to the south-west of the scheme. , It has been designed for supporting Roesel's bush cricket (*Metrioptera roeselii*), Stockmoor CWS is located 370m to the west of the scheme. It has been designated for the interconnecting rhyne network containing legally protected species and nationally rare and nationally scarce invertebrates	A cluster of existing species records (from SERC) is located approxaimtely 400m to the west of the site. It appears that these records all relate to Stockmoor CWS, but that they may have been recorded elsewhere on this widespread CWS. The records include various bat species, water vole (*Arvicola amphibious*), otter and great silver water beetle (*Hydrophilus piceus*). Serc also provided three records of barn owl (*Tyto alba*) within 500m of the site.

Table 2.2 Extended Phase 1 Habitat Survey Results for the Highway Improvement Sites

Scheme	Flora	Fauna
A38 Bristol Road/The Drove	This scheme is located in central Bridgwater and is bounded by a mixture of residential houses and commercial properties. The area within the red line boundary comprises hardstanding (highway and pavement), a small area of garden at the fronts of 131, 133, 135 and 137 Bristol Road (all of which are predominately laid to lawn and bordered by small ornamental hedges and fences) and a small area of specie- poor amenity grassland verge outside of the commercial property at 139 Bristol Road.	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species occur on the site.
A38 Taunton Road/Broadway	The scheme is located in the centre of Bridgwater and is bordered by commercial properties, with associated car parks, residential properties and directly to the north by a small park with mature trees around its boundary. The area inside of the red line boundary comprises predominantly hardstanding (highway and pavement) although there are small areas of amenity grassland, dominated by species such as perennial rye-grass (*Lolium perenne*), and ornamental shrub landscape planting. At 6 Taunton Road (Malvern Court) a mature small-leaved lime (*Tilia cordata*) is located on the boundary of the scheme.	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species occur on the site, with the potential exception of breeding birds in the landscape planting. The lime tree at 6 Taunton Road does not support features which could be used by roosting bats.
A38 Bristol Road/Wylds Road	The scheme is located in central Bridgwater and is bordered by a mixture of commercial properties and residential houses.	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species

Scheme	Flora	Fauna
	The area within the red line boundary comprises hardstanding (comprising highway and pavement) and species-poor amenity grassland verge, dominated by perennial rye-grass and cock's-foot (*Dactylis glomerata*), with scattered landscape planting (mainly whitebeam - *sorbus spp.*) and ruderal vegetation.	occur on the site, with the potential exception of breeding birds in the landscape planting. The trees within the site do not support features which could be used by roosting bats.
Wylds Road/The Drove	This scheme is located in the centre of Bridgwater and is bordered by commercial properties, with associated car parks, and an area of brownfield land (located on the corner between Wylds Road and the Northern Distributor Road). The area within the red line boundary comprises predominantly hardstanding (highway, pavement and car parks). There are also small areas of species-poor amenity grassland verge, dominated by perennial rye-grass and cock's-foot, ornamental shrub landscape planting and young broad-leaved trees such as ash (*Fraxinus excelsior*). In addition, there is a small extent of ephemeral/short perennial vegetation dominated by gravel and species such as buddleia (*Buddleja davidii*), scentless mayweed (*Tripleurospermum inodorum*) and perennial sow thistle (*Sonchus arvensis*). This area does not support a diverse 'mosaic' type assemblage of flora or faunal species and may be relatively young in age.	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species occur on the site, with the potential exception of breeding birds in the landscape planting. The trees within the site do not support features which could be used by roosting bats.
A39 Sandford Corner	Sandford corner is located outside of Bridgwater and is bordered by arable fields and hedgerows. The area inside of the red line boundary comprises hardstanding (highway, pavement and a culvert), semi-improved rough grassland verge, trees, fences, hedgerows and scrub habitat. The semi-improved, rough grassland verge is moderately species-diverse (although it is regularly mown), comprising species such as false oat-grass (*Arrhenatherum elatius*) and cock's-foot, with herb species such as meadow vetchling (*Lathyrus pratensis*), bush vetch (*Vicia sepium*) and birds-foot trefoil (*Lotus corniculatus*) also present. Two semi-mature ash trees are present adjacent to the culvert in the eastern part of the site. The largely intact hedgerows which border the rough grassland, and which are present along the B3339, are dominated by species such as elder (*Sambucus nigra*), dogwood (*Cornus sanguinea*), bramble (*Rubus fruticosus agg.*) and hawthorn (*Crataegus monogyna*). These would not qualify as ecologically important under the Hedgerows Regulations 1997.	No evidence of protected or notable species was found during the survey. Based on the generally poor quality habitats that are present there is limited potential for any such species to occur on the site, with the exception of the following • small number of reptiles could occur in the rough grassland verge and scrub; • the trees and hedgerows could provide habitat for breeding birds; • the hedgerows may be used by commuting bats, but the provides very limited foraging opportunities and no suitable roosting habitat; and • due the presence of water features (drains) within 500m of the site, which are not separated from the site by barriers to movement, great crested newts could utilise the hedgerows and grassland verge habitat in their terrestrial phase.
M5 Junction 23 (Including	This scheme is located on the outskirts of Bridgwater and is bordered by farmland in mixed pastoral and arable use.	No evidence of protected or notable species was found during the survey.

Scheme	Flora	Fauna
Dunball Roundabout)	The area inside of the red line boundary comprises hardstanding (highway and pavement), semi-improved species-poor grassland and improved grassland verge, young trees, fences, and scrub habitat	Based on the poor quality habitats that are present it is unlikely that any such species occur on the site, with the potential exception of breeding birds in the landscape planting. The trees within the site do not support features which could be used by roosting bats.
Washford Cross Roundabout	The Washford Junction is located 1.5km to the west of Williton and is bordered by arable fields, hedgerows and buildings. The area inside of the red line boundary comprises hardstanding (highway) and a mixture of amenity grassland, rough semi-improved grassland verge, and hedgerows adjacent to the arable fields. The species-poor amenity grassland is regularly maintained by mowing. The rest of the verge habitat within the red line boundary comprises semi-improved rough grassland dominated by grass species, such as false oat-grass and cock's-foot, and common herb species such as doves-foot crane's-bill (*Geranium molle*) and common toadflax (*Linaria vulgaris*). The hedgerow along the northern edge of the junction is species-poor and defunct in places. It has also been heavily flailed to increase visibility at the junction. Species present include bramble, hawthorn (*Crataegus monogyna*), hazel (*Corylus avellana*) and elder, as well as hart's-tongue fern (*Phyllitis scolopendrium*) and honeysuckle (*Lonicera periclymenum*). A further section of hedgerow is present to the east of the junction. This hedgerow is intact and is dominated by English elm (*Ulmus minor var. vulgaris*). Neither hedgerow would qualify as ecologically important under the Hedgerow Regulations 1997. There are also a number of semi-mature, broad-leaved trees within the red line boundary. Species present include ash (*Fraxinus excelsior*) and sycamore (*Acer pseudoplatanus*).	No evidence of protected or notable species was found during the survey. Based on the generally poor quality habitats that are present there is limited potential for any such species to occur on the site, with the exception of the following • small number of reptiles could occur in the rough grassland verge and scrub; • the trees and hedgerows could provide habitat for breeding birds; and • the hedgerows may be used by commuting bats, but the provides very limited foraging opportunities and no suitable roosting habitat. Although there are water features within 500m of the scheme, these are isolated from the site by busy roads and large areas of intensively farmed arable land. Similarly the water features at the aquarium are separated from the scheme footprint by large areas of hardstanding (e.g. car parks and buildings). Therefore, if great crested newts are present in these water features they will not be present in the scheme's footprint.
Junction improvements at Clayland Corner	Clayland Corner is located approximately 2km to the east of Stogursey. It is bordered by fields and a house with gardens. The area inside of the red line boundary comprises hardstanding (highway), semi-improved rough grassland and neutral grassland verge (Claylands Corner CWS) bordered by hedgerows. The grassland within the CWS is botanically diverse and supports a mixture of unimproved neutral grassland species. This is bordered by a tall hedgerow and a section of mature bramble scrub.	No evidence of protected or notable species was found during the survey. Based on the small area of the site there is limited potential for any such species to occur on the site, with the exception of the following • small number of reptiles could occur in the rough grassland verge and scrub; • the trees and hedgerows could provide habitat for breeding birds; • the hedgerows may be used by commuting bats, but the provides very limited

Scheme	Flora	Fauna
	The areas of semi-improved rough grassland verge, outside of the CWS, also support a diversity of grassland species, including agrimony (*Agrimonia eupatoria*) and tufted vetch (*Vicia cracca*), but are more impoverished, probably due to a more intensive mowing regime. The intact hedgerows which border the junction are dominated by species such as hawthorn, backthorn (*Prunus spinosa*), hazel and bramble. None are considered to be ecologically important under the Hedgerows Regulations 1997. There are several small trees, including oak (*Quercus robur*), ash (and English elm associated with the hedgerows. A number of the elm trees are dead.	foraging opportunities and no suitable roosting habitat; and • due the presence of water features within 500m of the site, which are not separated from the site by barriers to movement, great crested newts could utilise the hedgerows and grassland verge habitat in their terrestrial phase.
C182 Farringdon Hill Lane Horse Crossing	The scheme is located on the C182 on the main access road HPC. It is bordered by fields in arable use and hedgerows. The area inside of the red line boundary comprises hardstanding (highway) and semi-improved, rough, grassland verge bordered by hedgerows. The existing horse crossing point is characterised by scrub, dominated by bramble, and young broad-leaved trees such as field maple (*Acer campestre*) and hazel. Semi-improved rough grassland dominates the verge habitat bordering the existing crossing point. Species present include hedge bedstraw (*Galium mollugo*), ribbed melilot (*Melilotus officinalis*), tufted vetch and meadowsweet (*Filipendula ulmaria*). The hedgerows which border the scheme are largely intact and are frequently associated with banks or dry ditches. Hedgerow species include hawthorn, field maple (*Acer campestre*), hazel and elder. Young field maple trees are located along the hedgerow to the west of the junction. None of the hedgerows present within the red line boundary would qualify as ecologically important under the Hedgerow Regulations 1997.	No evidence of protected or notable species was found during the survey. Based on the small area of the site there is limited potential for any such species to occur on the site, with the exception of the following • small number of reptiles could occur in the rough grassland verge and scrub; • the trees and hedgerows could provide habitat for breeding birds; • the hedgerows may be used by commuting bats, but the provides very limited foraging opportunities and no suitable roosting habitat; and • due the presence of water features within 500m of the site, which are not separated from the site by barriers to movement, great crested newts could utilise the hedgerows and grassland verge habitat in their terrestrial phase.
Cannington High Street	Cannington High Street is located in the centre of Cannington village. It is bordered on all sides by buildings within the village. Cannington High Street comprises a mixture of houses and shops along the main road through the village.	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species occur on the site.

Scheme	Flora	Fauna
Huntworth Roundabout	This scheme is located on the outskirts of Bridgwater and is bordered by a business park, farmland in mixed pastoral and arable use, and a newly constructed housing estate. The area inside of the red line boundary comprises hardstanding (highway and pavement), improved grassland verge, young trees and fences. The improved grassland verge is routinely kept short through mowing. Species present include cock'sfoot, Yorkshire-fog, false oat-grass and a mixture of herb species including yarrow (*Achillea millefolium*), ribwort plantain (*Plantago lanceolata*), creeping cinquefoil (*Potentilla reptans*) and selfheal (*Prunella vulgaris*). A small extent of verge to the south of the roundabout is less frequently managed and supports a small area of tufted hair-grass (D*eschampsia cespitosa*). Planted over a bund, to visually screen the business park, are young broad-leaved trees such as hawthorn, blackthorn and sycamore (*Acer pseudoplatanus*).	No evidence of protected or notable species was found during the survey. Based on the poor quality habitats that are present it is unlikely that any such species occur on the site, with the potential exception of breeding birds in the landscape planting. The trees within the site do not support features which could be used by roosting bats.

APPENDIX 20Q: SHELDUCK SURVEY BASELINE INFORMATION

Appendix 20Q - Shelduck Survey Baseline Information

1. Introduction

AMEC Environment & Infrastructure UK Ltd. was commissioned in July 2011 to undertake a survey of the rafting behaviour of shelduck (*Tadorna tadorna*) using Bridgwater Bay in the vicinity of Hinkley Point. The main aim was to ascertain how the area in the vicinity of the proposed jetty development, which forms part of the development proposals for Hinkley Point C, is used by rafting shelduck, with reference to tidal movements and disturbance.

2. Methodology

The surveys were carried out for three weeks within the peak period of use of the area by moulting adult birds. The dates on which the surveys were carried out, including relevant start times and states of tide are presented in **Annex A**.

Each survey started at a high or a low tide and was carried out for a period of six hours within an area that was visible from a vantage point close to the location of the proposed jetty development. The area that was surveyed is referred to in this report as the 'viewshed' (see **Figure 20Q.1**). Data were plotted on 1:10,000 scale maps showing 400m grid squares. Weather data, including cloud cover, and wind speed and direction, were recorded at the start and updated with any changes that occurred during the survey period.

The area visible from the viewshed was scanned with binoculars and a telescope in order to detect any groups of shelduck. Approximate distances were recorded by plotting compass bearings on the survey maps and relating them to markers (notably the existing Hinkley Point water intake - 'the water intake'). When flocks were detected, their location was recorded on a survey map and a reference number was assigned to each; also noted was other relevant information, including the number of individuals and what they were doing, using the following categories:

- roosting – birds with head under wing;
- loafing – birds scattered, pointed in different directions;
- swimming – birds all pointing in similar direction; and
- feeding – birds observed with heads up before brief 'dabbling behaviour'.

Every five minutes the location of the flock and all other data were updated. However, if the flock numbers had not changed, or if no new birds were recorded within a five minute period, no update record was made. If the original flock was joined by other individuals, the total count was updated. If during the five minute interval the flock split into smaller flocks, the largest was counted and followed and its new location was noted. Over each six hour period, the peak count of shelduck was also recorded, which included any scattered individuals within the viewshed, which did not constitute a discrete flock, as well as any flocks that were present.

During the survey period, any recorded disturbance was noted and plotted on the survey map. Causes of disturbance included the presence of boats, walkers on the beach and helicopters using the firing range to the west.

3. Results

3.1 Shelduck Vantage Point Surveys

Fourteen vantage point surveys were undertaken between 19/07/11 and 05/08/11. The results are set out in **Annex A**, which includes data on the flocks that were being observed at each survey time and a maximum number of birds that were recorded within the viewshed during each survey visit. Summary descriptions of shelducks' rafting behaviour for each survey visit are presented below.

Survey Visit 1: 19/07/11

During the survey period, a peak count of approximately 250 birds was recorded, comprising scattered birds and discrete flocks within the viewshed; a peak flock count of approximately 120 shelduck was recorded. Birds were largely grouped in six discrete flocks (A-F) throughout the survey period, although the flocks often fluctuated in size and sometimes became disaggregated. Over the period, birds were recorded drifting and occasionally swimming westwards with the tide, from approximately due west and immediately to the north of the water intake. From these areas, birds were recorded moving with the tide over a distance of between 450 – 1,400m. Birds were recorded no closer than 190m from the proposed jetty location (these birds were loafing).

Survey Visit 2: 20/07/11

During the survey period, a peak count of approximately 1,100-1,300 birds was recorded, comprising all scattered birds and discrete flocks within the viewshed; a peak flock count of approximately 450 shelduck was recorded. Most birds were recorded loafing further than 700m from the proposed jetty location. During the early part of the survey period, birds were recorded drifting and swimming with the tide for up to 1,800m, whereas later, as the tide was going out, some flocks were also recorded swimming with as well as against the tide. Throughout much of the survey, birds were grouped in scattered flocks (A-C), swimming gradually westwards from north of the water intake. Birds were recorded no closer than 440m from the proposed jetty location (these birds were swimming westwards).

Survey Visit 3: 21/07/11

During the survey period, a peak count of approximately 150 birds was recorded, comprising all scattered birds and discrete flocks within the viewshed; a peak flock count of approximately 115 shelduck was also recorded. This flock was recorded 200-400m beyond the water intake and located approximately 1.1km to the north-west of the proposed jetty location. A second flock of 30 birds was recorded gradually drifting westwards from the larger group, before swimming back eastwards, which was likely to be a result of the slackening tide. Birds were recorded no closer than 480m from the proposed jetty location (these birds were loafing).

Survey Visit 4: 22/07/11

During the survey period, a peak count of approximately 265 shelduck was recorded, mainly comprising three discrete flocks (A-C) in addition to scattered birds; a peak flock count of 95 birds was recorded. All three flocks were observed loafing and drifting gradually westwards with the tide. Birds were recorded no closer than 1km from the proposed jetty location (these birds were loafing).

Survey Visit 5: 25/07/11

During the survey period, a peak count of 16 shelduck was recorded, with this also being the peak flock count of birds recorded during the survey. This single small group of birds drifted into view from the east, before gradually swimming eastwards against the tide (although the water was probably quite slack at this stage) and out of view again. Birds were recorded no closer than 1.75km from the proposed jetty location (these birds were loafing).

Survey Visit 6: 26/07/11

During the survey period, a peak count of one shelduck was recorded during the survey. This was a juvenile bird that flew eastwards along the shoreline without landing.

Survey Visit 7: 27/07/11

No shelduck were recorded during the survey.

Survey Visit 8: 28/07/11

During the survey period, a peak count of approximately 50 shelduck was recorded, with this also being the peak flock count of birds recorded during the survey. This single discrete group of birds was recorded loafing approximately 600m due north of the water intake and either drifting or swimming gradually eastwards with the high tide out of viewing range. Birds were recorded no closer than 2km from the proposed jetty location (these birds were loafing).

Survey Visit 9: 29/07/11

During the survey period, a peak count of three shelduck was recorded, with this also being the peak flock count of birds recorded during the survey. However, these birds were not mapped due to their range of approximately 1-1.5km.

Survey Visit 10: 01/08/11

During the survey period, a peak count of approximately 1,700 birds was recorded, comprising scattered birds and discrete flocks; a peak flock count of 190 shelduck was recorded. Over this period, these birds were grouped loosely into six discrete flocks (A-F), all of which were recorded drifting gradually westwards with the tide. Overall, the birds ranged over an area from

300m north-east of the water intake extending 2.5km to the west of the intake. Birds were recorded no closer than 390m from the proposed jetty location (these birds were loafing).

Survey Visit 11: 02/08/11

During the survey period, a peak count of approximately 500 birds was recorded comprising all scattered birds and discrete flocks within the viewshed; a peak flock count of 50 shelduck was recorded. Four discrete flocks (A-D) were observed during the survey period, each of which was recorded rapidly drifting westwards with the wind and tide. Similar to the survey on 01/08/11, the overall area where shelduck were mapped comprised a location approximately 250m to the north-east of the water intake extending approximately 2.5km to the west. Birds were recorded no closer than 650m from the proposed jetty location (these birds were loafing).

Survey Visit 12: 03/08/11

During the survey period, a peak count of approximately 500 birds was recorded, comprising scattered birds and discrete flocks; a peak flock count of 50 shelduck was recorded. Five discrete flocks (A-E) were observed during the survey period, all of which were recorded drifting with the tide gradually westwards. The overall area where shelduck were mapped comprised a location to the north-east of the water intake extending approximately 3km to the west. Birds were observed feeding around a location approximately 600-800m to the north and north-east of the proposed jetty location, with the closest record to the jetty location being of loafing birds no closer than 540m away.

Survey Visit 13: 04/08/11

During the survey period, a peak count of approximately 400 birds was recorded comprising scattered birds and discrete flocks; a peak flock count of approximately 60 shelduck was recorded. Six discrete flocks (A-F) were observed during the survey period, all of which were recorded gradually drifting westwards with the tide. The overall area where shelduck were mapped comprised a location 400m to the east of the water intake extending approximately 3.5km to the west. Birds were recorded no closer than 400m from the proposed jetty location (these birds were loafing).

Survey Visit 14: 05/08/11

During the survey period, a peak count of approximately 600-700 birds was recorded, comprising scattered birds and discrete flocks; a peak flock count of approximately 60 shelduck was recorded. Five discrete flocks (A-E) were observed during the survey period, all of which were recorded gradually drifting westwards with the tide. The overall area where shelduck were mapped comprised a location approximately 600m to the east of the water intake extending approximately 3.5km to the west. Birds were recorded no closer than 520m from the proposed jetty location (these birds were loafing).

3.2 Recorded Numbers and Behaviour

3.2.1 Shelduck Numbers

The peak flock count during the survey period was approximately 450 birds; flock numbers ranged from 3-450 but generally comprised between 50-100 birds. Flock numbers tended to be very loose, with discrete flocks often merging or breaking up. The greatest daily peak counts of shelduck within the viewshed comprised approximately 1,700 birds on 01/08/11 and 1,100-1,300 birds on 20/07/11.

3.2.2 Rafting Behaviour

During ten of the fourteen survey visits, shelduck were recorded loafing and generally drifting out with the tidal current in a westerly direction. Discrete flocks and scattered aggregations were most often recorded due east of the water intake to approximately 3km to the west. On one occasion, during a low to high tide survey, a flock was recorded drifting in with the tide, approximately 500m to the north-east of the water intake. In addition, on several occasions, small groups of shelduck were recorded actively swimming against the tide or slack water.

Aggregations of birds were recorded feeding over an area of approximately 2km and between 500 – 700m from the mean low water mark (MLW).

3.2.3 Birds Recorded Rafting within 500m of the Proposed Jetty

Rafting shelduck were recorded within 250m of the proposed development site on one occasion (19/07/11), when there were 21 birds approximately 190m to the north-west of the proposed jetty. In addition to this record, birds were recorded rafting within 500m of the proposed development site on two occasions during the survey period. There were two birds approximately 375m to the north-west of the proposed jetty on 01/08/11 and eight birds approximately 450m north of proposed jetty on 04/08/11.

3.2.4 Recorded Effects of Localised Disturbance

On several occasions, dog-walkers with several dogs as well as sporadic Land Rover activity were recorded along the shoreline. However, on each occasion, loafing birds (which at that time were situated more than 500m offshore), exhibited no disturbance behaviour. On one occasion (Survey 10 – 01/08/11), a yacht was recorded heading in a southerly direction, shortly after appearing to have passed through a line of shelduck, with there no evidence of the bird having been disturbed.

4. Conclusions

The vantage-point surveys of rafting shelduck in July and August 2011 demonstrated that the majority of activity recorded was at a considerable distance offshore. Aggregations of birds were most regularly recorded approximately 500-800m from the MLW, and approximately 500m beyond the proposed development site. A flock of 21 rafting birds was recorded within 250m of the proposed jetty location on one occasion. In addition to this flock, there were only two occasions when rafting birds were recorded within 500m of the proposed jetty location.

The majority of activity was recorded in a wide arc, which extended from the front of Hinckley Point B (approximately 0-100m from MLW), approximately 4km westwards. Within this area, flocks were often diffuse and numbers constantly changed, with individuals flying to/from flocks regularly (i.e. not all birds present were in moult). A peak flock count of 450 birds was recorded, although the majority of discrete flocks numbered less than 100 individuals. Rafting birds spent most time drifting in the same direction as the tidal current but on occasion swam against the tide up to 500m.

There was no evidence of shelduck being disturbed by the small number of potential disturbance events that were recorded.

37	1730	-		
Peak count of birds within study area: 265				

SURVEY VISIT 5: 25/07/11, 1400 – 2000, Wind: 3-4 W; Cloud Cover: 3; High to Low Tide; LW Time: 14.12.

Flock Reference Number	Time	No. of Individuals within Discrete Flock	Activity	Notes
A1	1905	16	Loafing	Drifted in from east.
A2	1910	16	Loafing	Flock splitting up and moving east.
A3	1915	16	Loafing	
A4	1920	16	Loafing	Moving around Hinkley Point, out of view.
A5	1925	16	Loafing	

Peak count of birds within study area: 16

SURVEY VISIT 6: 26/07/11, 0845 – 1445, Wind: 0-1 E; Light Showers; Cloud Cover: 7; Low to High Tide; LW Time: 09.14

Flock Reference Number	Time	No. of Individuals within Discrete Flock	Activity	Notes
-	1215	1	Flying	Juvenile bird flew past to east.

Peak count of birds within study area: 1

SURVEY VISIT 7: 27/07/11, 1040 – 1640, Wind: 2 ENE; Cloud Cover: 4-8; Low to High Tide; LW Time: 10.28.

Flock Reference Number	Time	No. of Individuals within Discrete Flock	Activity	Notes
-	No shelduck recorded during survey period.			

Peak count of birds within study area: 0

SURVEY VISIT 8: 28/07/11, 1120 – 1720, Wind: 3-4 W by N; Cloud Cover: 8; Low to High Tide; HW Time: 17.50

Flock Reference Number	Time	No. of Individuals within Discrete Flock	Activity	Notes
A1	1120	50	Loafing	Accurate count impossible due to range and choppy seas.
A2	1125	50	Loafing	
A3	1130	50	Loafing	
A4	1135	50	Loafing	
A5	1140	50	Loafing	
A6	1145	50	Loafing	
A7	1150	50	Loafing	
A8	1155	50	Loafing	
A9	1200	50	Loafing	Flock barely visible, no longer countable, drifting or swimming outside the viewshed.
-	1300	-		
-	1430	-		
-	1530	-		
-	1600	-		
-	1615	-		

Peak count of birds within study area: 50

SURVEY VISIT 9: 29/07/11, 1230 – 1830, Wind: 2-3 NE; Light Showers; Cloud Cover: 8; Low to High Tide; HW Time: 18.42

Flock Reference Number	Time	No. of Individuals within Discrete Flock	Activity	Notes
-	1230	3	Loafing	Birds beyond range of viewshed, therefore not plotted on map.
-	1300	3	Loafing	

Peak count of birds within study area : 3

SURVEY VISIT 10: 01/08/11, 0840 – 1440, Wind: 1-2 SE; Cloud Cover: 8; High to Low Tide; HW Time: 08.40

Peak count of birds within study area: 600-700

APPENDIX 20R: EXISTING, LOST AND FUTURE HABITAT AREAS WITHIN THE HPC DEVELOPMENT SITE

Appendix R
Existing, Lost and Future Habitat Areas within the HPC Development Site

Habitat Type	Existing Areas	Areas Lost	Areas once Site is Operational*
Broad-leaved woodland (not plantation)	3.5ha	3.3ha	39.7ha (of which 39.5ha are to be created)
Plantation broad-leaved woodland	3.5ha	3.5ha	n/a
Scrub	1.1ha	1.1ha	0.9ha
Calcareous grassland	1.2ha**	1.2ha**	17.7ha
Agriculturally improved grassland	30.6ha	30.6ha	n/a
Species-poor semi-improved grassland	16.1ha	16.1ha	n/a
Species-rich hay meadow	n/a	n/a	30.9ha
Arable	97.6ha	97.6ha	3.8ha (Farmland Birds Annual Cover Crop)
Agricultural land	(included within Arable/ Agriculturally improved grassland/ Species-poor semi-improved grassland above)	(included within Arable/ Agriculturally improved grassland/ Species-poor semi-improved grassland above)	16.0ha
Wetland (including ponds)	<0.01ha	<0.01ha	0.43ha
Linear Features	**Existing Length**	**Length Lost**	**Length once Site is Operational***
Species-rich hedgerow	7.7km	5.8km	13.1km (of which 11.2km are to be created)
Species-poor hedgerow	3.4km	3.4km	n/a
Watercourses (excluding Bum Brook and including Holford Valley ditches)	2.0km	2.0km	1.2km

* All areas of habitat that are included in this column of the table are newly created unless otherwise noted. The areas of restored habitat have been measured within the HPC development site boundary up to the HPC permanent development security fence.

** Bishop's Wood (area 2.3ha) supports calcareous grassland but has been included within this table as woodland (this is because, in the absence of the development, woodland would be the dominant vegetation type)

APPENDIX 21A: ENVIRONMENTAL IMPACT ASSESSMENT RADIOLOGICAL TECHNICAL NOTE

Environmental Impact Assessment Radiological Technical Note

May 2011

EXECUTIVE SUMMARY

Électricité de France (EDF) proposes the construction and operation of a power station based on two European Pressurised Water Reactors (UK EPRs) at Hinkley Point, near Bridgwater in Somerset. The total electrical output of 3,300 MW(e) will be enough to supply the needs of approximately 5 million homes and a range of shared facilities. The planned site is adjacent to the existing Hinkley Point 'B' (HPB, an operational AGR power station, due to close in 2016) and Hinkley Point 'A' (HPA, a Magnox reactor power station, currently in decommissioning). The new twin EPR power station will be designated as Hinkley Point 'C' (HPC).

This EIA Technical Note summarises the radiological assessments carried out in support of the environmental permitting of the HPC EPRs, as required under the 2010 Environmental Permitting Regulations. The main assessment deals with the prospective radiation doses to infants, children and adults in two 'candidate critical groups' who are exposed to continuous, routine gaseous radioactive discharges (to the atmosphere) and liquid radioactive discharges (to the Bristol Channel) from the two EPRs over an operational life of 60 years. The discharge values used in the dose assessment are derived from operational feedback from current PWRs (of similar design to the UK EPR) and are appropriate for carrying out a site-specific radiological assessment for the HPC development. The assessment includes the impact of direct radiation due to on-site facilities used for the storage of spent fuel and intermediate level waste (ILW).

Together, these assessments allow the Critical Group for the HPC development to be identified (the primary regulatory requirement to support an application for the authorisation of radioactive discharges).

There are separate assessments covering i) possible short-term discharges (one months' routine discharge in a single day); ii) the transport of a range of radioactive materials onto and off the HPC site; iii) future impacts due to potential build-up of nuclides in the environment off-site after 60 years operation of the two EPRs; iv) an assessment of the collective dose to the UK, European and World populations and v) an assessment of impacts on non-human species in four representative habitats around the site, including site specific species (bats and badgers).

The dose to members of the public during the construction phase of HPC and due to any potential pre-existing radioactive contamination in soil or water in the construction area is also considered.

The assessments include prospective radiation doses, were the HPA and HPB sites to continue to discharge radioactive liquids and gases at their current authorised limits, in parallel with those from the future EPRs planned by EDF. In view of the planned closure of HPB in about 2016 (which will then enter a decommissioning phase) with HPA being further advanced in its current decommissioning programme, this is an unlikely scenario. Furthermore, neither HPA nor HPB has, to date, discharged at the authorised limits assumed in this part of the assessment. The scenarios covered prospective doses to the candidate critical groups (above) a collective dose assessment and that due to build-up from all three reactors. This part of the assessment is completed with an estimate of the Total Dose for the

Hinkley Point site, that is, the dose that might be received by a member of the public close to the site and due to discharges from the HPA, HPB and HPC reactors and those due to historic, off-site man-made sources of activity.

All of the prospective radiation doses for the scenarios considered are estimated using standard UK protocols and take full account of local conditions that could affect the final doses received. Generally, the conditions assumed provide for a bounding assessment of prospective doses due to either HPC alone or those due to discharges from the Hinkley Point site as a whole. The prospective doses estimated are then compared against a range of UK-specific dose limits and guidelines (recommended by the Environment Agency in their guidance on the assessment of public doses). Where applicable, they are also compared with the public dose limit for radiation from man-made sources (1,000 μSv y^{-1}, but which excludes that from medical exposures) the local and UK average natural background radiation dose and with man-made background (that all represent involuntary sources of risk) and with some sources of radiation exposure that represent voluntary sources of risk.

The main assessment considers three age groups (adult, child infant) in each of two candidate critical groups i) a Fishing Family who consume large amounts of locally caught seafood (and are therefore exposed to liquid discharges from the EPRs that will pass to sea) but who also eat locally grown produce (so are also exposed to gaseous discharges to the atmosphere) and ii) a Farming family who eat locally grown produce but also locally caught seafood. The food consumption patterns, location and other habits assumed for the people within each of these 'candidate critical groups' ensures they are 'representative persons' subject to the highest exposure to liquid and gaseous radioactive discharges from the HPC EPRs which bounds any that could occur during normal operations (that is operation at power to generate electricity and short periods when the reactors may be shutdown for refuelling). Both groups are also assumed to be exposed to a direct radiation ('shine') due to a proposed Interim Storage Facility for Spent Fuel (and one for Intermediate Level Waste) on the HPC site.

The highest prospective doses due to the HPC routine continuous discharges at the values used (plus that due to direct radiation due to waste stores) are 4.5 μSv y^{-1} to the infant and 2.5 μSv y^{-1} to the child in the '**Farming Family with marine and gaseous exposures**' which is therefore considered the **Critical Group for the proposed HPC EPRs**. These doses (and therefore those to all other members of the candidate critical groups) are well below the relevant dose criterion, that is, the 'new source constraint' of 300 μSv y^{-1} (and also well below a separate recommendation of 150 μSv y^{-1})[a].

[a] Based on ICRP's new recommendations on radiological protection, the UK's Health Protection Agency (HPA-RPD) proposes that for new nuclear power stations and waste facilities the constraint should be reduced (from the previously recommended value of 300 μSv y^{-1}) to some value less than 150 μSv y^{-1}. This remains a recommendation.

The prospective doses due to discharges from HPC are dominated by those due to C-14 (mainly in gaseous discharges and responsible for at least 90% of the dose to all members in both critical groups) with the remainder of the prospective dose (up to about 7%) being due to discharges of I-131 and H-3 (all other nuclides in the discharges each contribute to less than 1% of the prospective doses). Techniques have been optimised (and continue to be refined) in the design of the EPR and will be exercised during operation, to minimise gaseous and liquid radioactive discharges at source, ensure efficient abatement and therefore minimise the impacts of the discharges on the environment and ensure compliance with BAT (Best Available Techniques)[b].

The highest prospective doses due to planned short-term gaseous releases from an individual EPR on the HPC site are estimated to be up to 0.45 μSv per discharge to an infant (in a specific and separate critical group most exposed to the short-term discharges; doses to the 'candidate critical groups' are much less). This is less than the relevant regulatory dose criterion of 300 μSv y^{-1} (or the limit of 1,000 μSv y^{-1} for all man-made sources). All liquid discharges pass to the main cooling water system so that short-term liquid discharges from the EPRs will not occur and do not need to be considered in the assessments.

Radiation doses due to transport of radioactive materials to and from HPC considers low and intermediate level waste, new fuel and spent fuel. Depending on the transport scenario considered, the estimated doses to members of the public on the transport routes are in the range of 0.06 to 2 μSv y^{-1}. They are therefore much lower than the relevant dose criterion for this scenario, which is the public dose limit from man-made sources of 1,000 μSv y^{-1}. The scenarios modelled make a number of conservative assumptions about the proximity of the public to the transport operations. Together with the planned store for spent fuel on the HPC site (which will avoid the need for off-site transport of fuel until an extended period of cooling has been achieved) it is therefore unlikely that even these small assessed doses would be realised in practice.

The prospective dose to a member of the public walking past the HPC site and close to this spent fuel store and the store for ILW (based on a typical daily 20 minute recreational walk outside the site boundary and a conservative store design, which assumes the public dose limit on its outside walls) is estimated as 1.5 μSv y^{-1} which, again, is much less than the relevant dose criterion (the public dose limit from man-made sources of 1,000 μSv y^{-1}). Doses to occupants in the dwelling currently situated closest to the planned ISF are estimated as less than 0.002 μSv y^{-1} (and are even less for those in the two candidate critical groups).

[b] The UK Government's Department of Energy and Climate Change has recently issued statutory guidance stating that, where the prospective dose to the most exposed group of members of the public from discharges from a site at its current discharge limits is below 10 μSv y^{-1} the Environment Agency should not seek to reduce further the discharge limits that are in place, provided that the holder of the authorisation applies and continues to apply Best Available Techniques (BAT).

The *per caput* collective doses to the UK, European and World populations (truncated at 500 years) due to liquid and gaseous discharges from HPC are all of the order of a few nSv y^{-1}. They are therefore in the range of a few nSv y^{-1} that, in the Environment Agency interim guidance document on the assessment of prospective public doses, are stated "*should be ignored in the decision making process, as the associated risks are 'miniscule' with the contribution to total doses to individuals being insignificant*". C-14 accounts for between 95% and 100% of the collective dose to all of the populations considered, but all the collective doses (expressed as total Man Sv or the *per caput* doses to individuals) due to HPC discharges are much lower than those due to naturally occurring C-14 to the UK population alone.

Analysis of soil and groundwater and surface water from the construction area for the planned HPC EPRs shows naturally occurring nuclides at typical UK background values. Very small amounts of tritium were identified in some groundwater samples, but at concentrations below those allowed for in UK drinking water. A formalised public dose assessment due to HPC construction has therefore not been carried out. However, fugitive emissions of soil or water from construction or off-site transport or disposal of surplus soil would not be expected to give rise to radiological impacts any greater than those associated with any other form of large-scale construction project in the Hinkley Point area.

Doses due to build-up in the environment and those to non-human species due to HPC discharges are very small (and therefore summarised together with those due to cumulative Hinkley Point Site impacts, below).

The highest prospective dose due to HPC routine, continuous liquid and gaseous discharges, plus those from HPA and HPB (at their current authorised limits) was assessed as 17.2 µSv y^{-1} to the infant in the '**Farming Family with marine and gaseous exposures**' which is therefore considered the **Critical Group for the Hinkley Point site**. This prospective dose (and therefore those to all other age groups in both candidate critical groups) is well below the relevant regulatory dose criterion, that is, the 'site constraint' of 500 µSv y^{-1}. At least 47% of the cumulative site doses assessed are due to discharges from the HPB reactor. When this ceases operation in 2016 and enters its decommissioning phase, gaseous and liquid discharges from this part of the site will decrease appreciably. The cumulative Hinkley Point site doses assessed here (and the collective doses as well) will also therefore decrease. At this future juncture, realistically, only the small assessed doses due to the operational HPC EPRs would need to be considered for the site as a whole.

The prospective doses due to the build-up of activity in the environment due to discharges from either the Hinkley Point site as a whole or from HPC alone (the more realistic scenario) are estimated as between 0.018 µSv y^{-1} (to a possible future off-site construction worker) to 2.8 µSv y^{-1} (to a user of the marine environment).

The Total dose for a member of the public at the Hinkley Point site due to discharges from HPA, HPB and HPC and direct radiation and that due to off-site sources (such as those further up the Bristol Channel) is estimated as 61 $\mu Sv\ y^{-1}$ which is significantly less than the relevant dose criterion, that is the public dose limit for all sources of man-made radiation of 1,000 $\mu Sv\ y^{-1}$.

Overall, not only are all the prospective doses to individual members of the candidate critical groups due to HPC discharges (or those from the Hinkley Point site as a whole) below the relevant regulatory constraints (notably the site and source constraints laid down by the Environment Agency) but they are also all significantly less than the public dose limit of 1,000 $\mu Sv\ y^{-1}$. All of the individual doses assessed to the candidate critical groups or those from specific scenarios (such as transport or build-up) are much smaller than the average background dose from other man-made sources in the UK, that is about 410 μSv y-1 (nearly all of which is due to medical exposures). All of the assessed doses are also either comparable in magnitude to, or smaller than, those due to radiation doses from individual medical procedures (such as a dental or chest X-ray) or for, example, those received on a single aircraft flight (which is due to exposure to cosmic radiation at altitude).

The assessed doses to all organisms in all four of the representative habitats around the site and due to discharges from either the Hinkley Point site as a whole or from HPC alone (the more realistic scenario) are all less than 10 $\mu Gy\ h^{-1}$. This is a value below which the relevant guidance states that no further or more detailed assessments are required and which implies no measurable harm on any of these organisms due to liquid or gaseous discharges from either HPC alone or the cumulative discharges from the Hinkley Point site as a whole.

1.0 INTRODUCTION

This EIA Technical Note examines the potential impacts, and where required, mitigation of radiological discharges and exposure, during the construction and operational phases of the proposed development of the two European Pressurised Water Reactors (UK EPRs) at the Hinkley Point Site near Bridgwater in Somerset, to be known as Hinkley Point C (HPC). The total electrical output of the two EPRs will be 3,300 MWe which is sufficient to supply the needs of approximately 5 million homes and a range of shared facilities. The operational design life of the power station is 60 years.

A location map of the site is shown in Figure 1. The HPC site is adjacent to the existing Hinkley Point A (Magnox) and Hinkley Point B (AGR) nuclear power stations and lies on the south side of Bridgwater Bay that forms part of the Bristol Channel. The planned site for HPC spans two areas of land, the largest currently consisting of agricultural land, the other smaller part being within part of the existing Hinkley Point Power Station Complex.

The Hinkley Point B (HPB) site is occupied by an AGR power station that is in operation, with a power output of 860 MWe. HPB is due to cease operation in 2016 after which it will enter a phase of decommissioning. The Hinkley Point A (HPA) site is occupied by a Magnox power station that ceased operation in 1999 and is currently being decommissioned, completion of which is due in about 2085-2100. Both of these reactor sites currently release liquid and gaseous radioactive discharges to the environment (the Bristol Channel and the atmosphere respectively) under authorisations issued by the Environment Agency of England and Wales.

The HPC EPRs (designated EPR West and EPR East) will use seawater cooling drawn from and then returned to the Bristol Channel, a route that will also serve for treated liquid radioactive discharges. Each EPR will have a single main stack for treated gaseous discharges, from various plant areas into the atmosphere. Minor gaseous discharges may occur from the turbine hall, maintenance facilities and store for spent fuel.

This EIA Technical Note covers:

- The legislation and regulatory background to radiation protection and control of radioactive discharges in the UK. This provides the background from which limits and guidelines used in the assessment are drawn.
- Methodology for the assessment. This also covers the risk assessment methodology and criteria against which the radiological impacts are to be assessed.
- The mitigation measures already in place in the UK EPR reactor design.
- Assessment of the residual impacts due to discharges specifically for the HPC site. The scope of impacts covered is described in the rest of this introduction (see below).

1.1 Scope of the Radiological Assessment

This EIA Technical Note describes the methods used for the radiological impact assessment and presents the results for the main phases of the proposed HPC development, as outlined in the Sections 1.1.1 and 1.1.2 below and the overall impact of the Hinkley Point Site.

1.1.1 Radiological Assessment of Impact of Construction Phase

This EIA Technical Note summarises the results of the radiological surveys that have been carried out on the proposed construction area for HPC, covering direct radiation, soil surveys and the analysis of surface water and groundwater. On the basis of the results obtained, it provides an assessment of potential radiological impacts on the public due to the construction phase itself that could be due to off-site fugitive emissions of dust from soil disturbance or discharge of water from, for example, dewatering operations.

1.1.2 Radiological Assessment of Impact of Operational Phase for HPC

Operational phase assessments for HPC (East and West) include radiological impacts on humans and non-human species due to liquid discharges to the Bristol Channel and gaseous discharges to the atmosphere. The main assessment deals with the annual prospective doses to two candidate critical groups exposed to direct radiation and due to liquid and gaseous discharges from HPC. There are separate assessments for prospective doses to other members of the public who may be exposed to short-term gaseous discharges (from a single EPR) or to the transport of radioactive materials on to and off the site and those to future off-site users (that are due to potential build-up of nuclides in the environment over the operational life of HPC). There is also an assessment of the prospective collective doses to the UK, European and World populations. Impacts to non-human species cover four separate habitats around the site.

1.1.3 Cumulative Hinkley Point Site Impacts

The Technical Note assesses the overall radiological impacts due to current liquid and gaseous discharges from the existing HPA and HPB reactor sites and thus the cumulative future impacts from the operation of all three licensed sites. For Hinkley Point A and Hinkley Point B, the assessment is based on discharges at the current authorised limits. The cumulative impacts estimated in the current report assume that discharges from these facilities continue for the next 50 years, and in parallel with those from the proposed Hinkley Point C EPRs. This leads to some uncertainties and probably conservatism in the final doses estimated, since during the next 50 years, Hinkley Point A and B Units will be in advanced stages of decommissioning and, in any case, have never discharged at their authorised limits.

Cumulative impacts cover the candidate critical groups, a collective dose assessment and that due to build-up.

1.1.4 Radiological Assessment of Impact of the Decommissioning Phase

The current Environmental Impact Assessment (EIA) does not address radiological impacts during future decommissioning of the EPR. These would be addressed under a separate EIA carried out under the separate legislative framework of the Nuclear Reactors (Environmental Impact Assessment for Decommissioning) Regulations (SI, 1998)[1].

2.0 LEGISLATION

The following sections provide an overview of the principle sources of legislation that apply to radiological protection, starting with international agreements and protocols and then describing how these cascade down through European legislation and are eventually implemented in the United Kingdom. A central requirement of much legislation centres on maintaining doses to members of the public and workers to ensure they are As Low As Reasonably Achievable (ALARA) or As Low As Reasonably Practicable (ALARP). The latter is specifically applied in the UK and requires the employer (or operator of a nuclear facility) to provide systems (engineered means, operational means and protective equipment) to reduce the radiation dose until the cost of implementing those measures (in time, trouble or money) is considered to be grossly disproportionate to the radiation risk averted. Both terms are, however, used in published UK regulatory guidance, ALARP generally by the Nuclear Installations Inspectorate (NII) and ALARA by the Environment Agency (in accordance with the Basic Safety Standards Directive (IAEA, 1996)[2].

2.1 International Legislation, Guidance and Recommendations

2.1.1 Human Radiological Protection Principles

The framework for radiation protection worldwide is based on the International Atomic Energy Agency (IAEA) Basic Safety Standard (BSS)[2]. Although the IAEA BSS has no legal standing *per se*, it is used by Member States as a basis for their legal radiological protection systems.

The scientific basis of the BSS[2] is based on the recommendations of the International Commission on Radiation Protection (ICRP). Its latest published recommendations are ICRP 103 (ICRP, 2007)[3]. However, the recommendations in current use within the BSS[2] are ICRP 60 (ICRP 1990) [4] owing to the time taken for the recommendations to become legally adopted in those States where they are applied. It is likely that the 2007 recommendations will be in place in the UK once HPC is operational.

Other organisations provide input into the IAEA BSS[2], including the Food and Agriculture Organisation of the United Nations; the International Labour Organisation; the Nuclear Energy Agency of the Organisation for Economic Co-operation and Development; the Pan American Health Organisation and the World Health Organization.

The principles for radiation protection described in the ICRP 60[4] recommendations and developed in the ICRP 103[3] recommendations are those of:

- Justification: Any decision that alters the radiation exposure situation should do more good than harm;
- Optimisation of protection: The likelihood of incurring exposures, the number of people involved and the magnitude of their individual doses

should all be kept as low as reasonably achievable, taking into account economic and societal factors; and

- Dose limitation: The total dose to any individual from regulated sources in planned exposure situations, other than medical exposure of patients, should not exceed the appropriate limits recommended by the ICRP.

2.1.2 Non-Human Radiological Protection

In the past, non-human species have been considered to be adequately protected by the radiation protection systems developed for the protection of humans. For example, ICRP 60[4] states that:

"*The Commission believes that the standard of environmental control needed to protect man to the degree currently thought desirable will ensure that other species are not put at risk. Occasionally individual members of non-human species might be harmed but not to the extent of endangering whole species or creating imbalance between species.*"

More lately, ICRP Publication 91 describes a framework for assessing the impact of ionising radiation on non-human species (ICRP, 2003)[5]. This was designed to harmonise with the existing ICRP approach to the protection of human beings, but not to set regulatory standards. It sets out a systematic, risk-based approach to assessing radiological impacts on non-human species. This approach has been reiterated in the ICRP 103[3] recommendations. Other organisations have developed assessment tools to determine the risk of radiation exposure to non-human species. These are described in later sections of this Technical Note.

Note the IAEA[2] and ICRP[3, 4] documents have no legal standing in their own right. However, they do influence the development of the legal system for radiation protection internationally.

2.1.3 Transport

The IAEA formulates regulations for the Safe Transport of Radioactive Materials that give standards of safety for radiation, criticality and thermal hazards to persons, property and the environment due to the transport of radioactive materials. The regulations were first published in 1961 and have been subject to periodic reviews, the latest of which were published in 2009 (IAEA, 2009)[6]. The IAEA also publish supporting advisory material and guidance.

In Addition, the United Nations publish Recommendations on the Safe Transport of Dangerous Goods known as the "Orange Book" (UN, 2009)[7] where goods are divided in to nine classes, Class 7 being radioactive materials. An expert group of the Economic and Social Council of the United Nations issued a resolution that entrusted the task of establishing recommendations for the safe transport of radioactive materials to the IAEA thus ensuring compatibility between IAEA regulations[6] and the "Orange Book"[7].

2.2 European Legislation, Guidance and Recommendations

2.2.1 Human Radiological Protection

The Euratom Treaty (EURATOM, 1957)[8] came into force on 1st January 1958 and established a European Atomic Energy Community, widely known as Euratom. Under Articles 31 and 32 of the Treaty, the Commission of the European Communities is required to develop radiological protection standards for application in Member States in three formats:

- Regulations - Apply directly to Member States;
- Directives and Decisions of Council - Set goals and standards that must be translated into Member States legislation; and
- Recommendations and communications – These are not mandatory.

Central to these and implementing the IAEA BSS (Section 2.1.1.) is Council Directive 96/29/Euratom BSS dated 13th May 1996, which lays down basic safety standards (BSS) for the protection of health of workers and the general public against the dangers from ionising radiations. This Euratom BSS[9] also provides the dose coefficients required to calculate doses to members of the public from intakes of radionuclides.

2.2.2 Non-Human Radiological Protection

In Europe, there are no regulations for the protection of non-human species from radiation hazards. However, the Habitats and Birds Directives (EC, 1992)[10] covers general requirements for the protection of non-human species (plants, animals) and their habitats. The regulators in the UK (the Environment Agency, Scottish Environment Protection Agency and Northern Ireland Environment Agency, 'the Environment Agencies') have a duty to comply with the implementation of these, in particular covering:

- Existing authorisations, consents, licences and permissions or variations for discharges of chemicals; and
- Ensuring that no Agency-authorised activity or permission results in an adverse effect, either directly or indirectly on the integrity of identified European sites (Natura 2000 sites).

2.2.3 Transport

In Europe, the IAEA Regulations for the Safe Transport of Radioactive Materials[6] have been implemented into separate regulations and agreements depending on the mode of transport. These are the "International Regulations Concerning the Carriage of Dangerous Goods by Rail" (RID) (UN, 2009)[11]; the European agreement for the "International Carriage of Dangerous Goods by Road" (ADR), (UN, 2009)[12] and the European agreement for the "International Carriage of Dangerous Goods by Inland Waterways" (ADN) (UN, 2009)[13].

2.3 UK Legislation, Guidance and Recommendations

2.3.1 Human Radiological Protection

A number of Acts and Regulations govern the exposure or potential exposure of workers and the general public to ionising radiations. The principle ones (that are supported by a wide range of Codes of Practice and guidance) are outlined below, together with their principal requirements.

The Nuclear Installations Act 1965

The Nuclear Installations Act 1965 (amended 1969)[14] governs nuclear installations in the UK by the issue of site licences by Her Majesty's Nuclear Installations Inspectorate (HMNII, now part of the Nuclear Directorate of the Health and Safety Executive). The licenses cover a standard set of 36 detailed requirements to be addressed by a site licensee covering, for example, management systems; safety cases, plant safety; construction; plant modifications; operations, accumulation/disposal of radioactive waste and decommissioning[15].

Ionising Radiations Regulations 1999;

Radiation exposure of the worker and the general public is regulated by the Ionising Radiations Regulations 1999 (IRR99) (SI, 1999)[16]. These regulations were made under the Health and Safety at Work, etc. Act 1974 and implement the Euratom Basic Safety Directive 96/29/Euratom. The regulations define the dose limits that meet the requirements of the ICRP and also specify that radiation exposures are as low as reasonably practicable (ALARP). The duty is on the employer or operator to ensure that these requirements, amongst others, are complied with. In the case of the general public, the effective dose limit is 1 mSv per annum from man-made sources.

Radioactive Substances (Basic Standards)(England and Wales) Direction 2000;

The Radioactive Substances (Basic Standards)(England and Wales) Direction 2000[17] implements the obligations of Euratom BSS Directive in England and Wales. The principle aims of the Direction require the Environment Agency in England to ensure, when exercising its duties and functions under the Environmental Permitting Regulations that:

- All public ionising radiation exposures from radioactive waste disposal are kept ALARA;
- The sum of doses arising from such exposures does not exceed the individual public dose limit of 1 mSv y^{-1};
- The individual dose from any single site does not exceed 0.5 mSv y^{-1} and;

- The individual dose received from any new discharge source since the 13th May 2000 does not exceed 0.3 mSv y^{-1}.

Note that these requirements are now subsumed into the more recent Environmental Permitting Regulations (see below).

Environmental Permitting Regulations

The use, accumulation, storage, disposal and discharge of radioactive materials in the UK was regulated via authorisations issued under the Radioactive Substances Act 1993 (RSA 93)[18] but together with Basic Standards Direction[17], more recently updated under the Environmental Permitting Regulations 2010[19]. These require that a person must not operate a regulated facility except under the authorisation of an Environmental Permit issued by the relevant regulatory body. This includes undertaking activities with radioactive substances, where a person uses premises for the purposes of an undertaking and that person disposes of radioactive waste from those premises.

The Environmental Permitting Regulations are regulated by the Environment Agency in England and Wales. It is the primary regulatory framework under which permits to make radioactive discharges (gas, solid or liquid) to the environment are issued to operators of premises, including licensed nuclear sites. On a Nuclear Licensed Site, the accumulation of radioactive waste is regulated by HMNII under a section of the Nuclear Installations Act[14], specifically site License Condition 32. A 'Memorandum of Understanding' between the Environment Agency and the HMNII ensures a consistent and seamless approach between the control of the radioactive wastes on the sites and any subsequent discharge or disposal.

Permits to discharge radioactive waste are only granted after a rigorous assessment process which includes a requirement to complete a prospective assessment of the radiological impacts on the public. More recently this has been extended to impacts on non-human species. The prospective dose assessments are determined using modelling. This is because it is not practicable to measure exposure directly (or in advance of the operations of the plant) and it is essential to show that any doses received would be below regulatory guidelines and also in accordance with the principles of ALARA (outlined above). Once these and other assessments are completed, there is a period of consultation on the Environment Agency's proposed decision as to whether to grant a permit (previously termed 'authorisation' under the previous regulatory framework). The permit will also impose a wide range of requirements to protect the public and environment by the permit holder. After issue, the permits will also subject to periodic reviews.

2.3.2 Best Practical Means (BPM) Environmental Optimisation and Best Available Techniques (BAT)

Schedule 23, Part 3 of the Environmental Permitting Regulations 2010[19] implements the relevant requirements of the Basic Safety Standards (BSS) Directive[9], namely that in relation to radioactive waste, all exposures to ionising radiation of any member of the public and of the population as a whole resulting from the disposal of radioactive waste are kept as low as reasonably achievable, economic and social factors being taken into account (ALARA).

"Best Available Techniques" (BAT) are the means an operator uses in the design and operation of a facility to deliver an optimised outcome i.e. in order to reduce exposures to ALARA. The fundamental aim in the application of BAT is to prevent and, where not practicable, minimise waste generation and discharges to the environment[20].

Importantly, the application of BAT is not merely concerned with abatement and other "end of pipe" controls. BAT applies across the whole life cycle of the plant from design, through procurement, construction, operation and final decommissioning. BAT applies to the operation, maintenance, testing, calibration, sampling, measuring, and analysis of relevant plant, systems and equipment. It also relates to the procedures and management systems that may impact on environmental performance.

Prior to the introduction of the Environmental Permitting Regulations under the UK's regulatory framework, authorisations granted in England and Wales for the discharge of radioactive waste required implementation of the Best Practicable Environmental Option (BPEO) and Best Practicable Means (BPM) as the means by which environmental optimisation was achieved. The application of BAT provides no different test with respect to environmental optimisation. Indeed, the Environment Agency has stated:

> "*We believe BAT to be broadly the same concept as best practicable environmental option (BPEO) and best practicable means (BPM) and to deliver the same level of environmental protection....We also consider that the process for assessing BAT is the same as that for BPEO/BPM*"[21]

BAT may be determined by comparison against international best practice and operational experience or through an optioneering process where meaningful alternatives are compared and will remain a requirement in the issue of permits under the new regulations[19].

As part of the Generic Design Assessment (GDA) of candidate nuclear power plant designs, the Environment Agency has published a Process and Information Document (PID) (Environment Agency, 2007)[22] requesting Parties provide information demonstrating that the design of the proposed facility has been optimised with respect to the environment and which includes:

- Significant waste generating and management process; description of the methods implemented to minimise waste arising and discharged or disposed of, along with a demonstration that they are the best practicable;

- Minimisation of arisings and disposal of waste during operation of the reactor; review of the design features;

- Forward planning and minimisation of the waste arising from decommissioning activities; review of the features of the particular candidate design;

- Methods of determination of discharges by demonstrating that the techniques and systems proposed for measurement and assessment of discharges and disposal of radioactive waste represent the best practicable means for such analyses; and

- Arisings, management and disposal of liquid waste streams, providing a demonstration that BAT and good practices are used to prevent direct or indirect discharges to groundwater, prevent or minimise emissions of pollutants from each significant effluent stream along with consideration of the means of control in the event of detection of unplanned radioactive or other contamination of the discharge.

As part of the GDA for the UK EPR, extensive demonstration of the use of BAT for abatement of discharges has already been achieved (see the Fundamental Safety Overview, Volume 3, D.7.4, 2008)[23] and further developed in the Pre-construction Environmental Report (UK EPR, Chapter 8, BAT sub-chapter 8.2)[24]. Demonstrating application of BAT is a pre-requisite to demonstrating that doses to the public and workers will be ALARA. It will remain an on-going consideration throughout the rest of the design, operational (and eventually, decommissioning) phases of the UK EPR[24]

NNB GenCo will be applying for a permit to dispose of radioactive waste from the proposed facilities of Hinkley Point. The submission that supports the permit will need to demonstrate that environmental optimisation through the application of BAT has been achieved. The permit requires the case that supports the application of BAT is maintained, reviewed and updated.

2.3.3 Radiological Protection due to Radioactive Transport in the UK

In the UK, the ADR[12] and RID[11] have been adopted in the Carriage of Dangerous Goods and the Use of Transportable Pressure Equipment Regulations 2009 (OPSI 2009) [25]. These regulations apply to the transport of radioactive materials by road and rail and detail any UK specific derogations. Dose limitation is enforced through the IRR99[16] for both members of the public and workers.

2.3.4 Radiological Protection of Non-Human Species in the UK

As for European legislation, in the UK there are no specific regulations for the protection of non-human species from radiation sources. However, UK regulations are in place to enforce the European Directives in the UK, the main one being Conservation (Natural Habitats) Regulations (SI, 1994)[26]. These implement the Habitats Directive (1992) in the UK and require steps to maintain and restore to favourable conservation status the habitats and species of EU Community level interest.

In the GDA Process & Information Document[22] the Environment Agency requires that an assessment of the likely impact of the radioactive discharges on non-human species be carried out. They refer to Environment Agency R&D Publication 128 (EA, 2002)[27] and make recommendations for carrying out generic radiation dose assessments. This was an interim publication, whilst a more comprehensive European model was in development. The modelling code ERICA, (Beresford, 2007)[28] funded under EURATOM within the EC 6th Framework Programme, was published in 2007.

3.0 METHODOLOGY

The following sections describe the methodology adopted for assessing the potential radiological impacts from the HPC development.

3.1 Summary of Approach

European and UK legislation outlines the requirements for an EIA and Environmental Statement to support planning for certain developments. This includes European Community Directive (85/337/EEC as amended by 97/11/EC, 1997)[29] 'On the Assessment of the Effects of Certain Public and Private Projects on the Environment' and the Town & Country Planning (Environmental Impact Assessment) (England & Wales) Regulations (1999)[30] and, more specific to the proposed HPC development, the Nuclear Reactors (Environmental Impact Assessment for Decommissioning) Regulations[1] and Electricity Works (Environmental Impact Assessment (England and Wales) 2000 regulations[31].

However, there is currently no statutory defined method for carrying out Environmental Impact Assessment (EIA) in the UK and in particular for assessing radiological impacts. General guidelines are available in, for example, the Department of the Communities and Local Government, 1999[32], IEMA, 2006[33], Environment Agency, 2002[34] and EIA, 2006[35]. Using these guidelines, the approach adopted in this EIA Technical Note is based on the following steps:

- Definition of the current baseline: For the radiological assessment for HPC, this consists of the average background radiation levels in the UK from all sources and the existing site specific radiation impacts, including those due to the HPA site (currently being decommissioned) and the HPB site (currently operating but due to enter its own decommissioning phase in about 2016);

- Impact assessment: This covers the prospective (broadly equivalent to predicted) radiological impacts from the HPC site and assessment of these against recognised radiological protection standards for a specified range of human and non-human receptors. The method assumes discharges from two UK EPRs on the Hinkley Point C site (designated for the purposes of this Technical Note as EPR East and EPR West). The discharge values used in the dose assessment are derived from operational feedback from current PWRs (of similar design to the UK EPR) and are appropriate for carrying out a site-specific radiological assessment for the HPC development. The discharges are assumed to be continuous, uniform, routine releases over an operational life of 60 years (excepting for the assessment of short-term gaseous releases). The discharges contain a specific range of radionuclides, the subsequent movement of which through the environment (air, water, soil) and into the food chain is predicted using a range of industry-standard computer models. The model parameters (wind direction etc.) are specific to the HPC site. The human receptors are formulated to be bounding in terms of the exposure pathways due to HPC discharges and their food consumption patterns, thus the levels of nuclides they are eventually exposed to and the doses they receive. Non-human species cover a generic range plus site-specific ones, based on ecological surveys;

- Proposed mitigation measures; and
- Assessment of any residual impacts after implementation of mitigation.

At the impact assessment stage, the development proposals are compared to the findings of the baseline environmental surveys and baseline data, to predict the potential impacts that may result from the development. This quantitative assessment will determine the overall level of significance of radioactive discharges on the populations and is considered in several stages:

- Step 1: Standard set of descriptions for each identified potential impact (spatial extent, i.e. site specific or wider impacts, beneficial, adverse, direct, indirect, temporal extent, reversible or irreversible, secondary or cumulative);
- Step 2: Assessment of the scale of the potential impact, the value and sensitivity of the receiving environment and the likelihood of the impact occurring; and
- Step 3: Determination of the degree of significance of the potential impact, using an impact assessment matrix (IAM) moderated by professional judgement where appropriate.

Once identified and described, the evaluation of the degree of significance of each potential impact is based on (1) the assessment of the value and sensitivity of the receptor and (2) the magnitude of the impact. This evaluation process provides a level of significance for each potential impact. Specific criteria for the assessment of each potential impact have been developed for EIAs, giving due regard to the following:

- Values of the receptor / resource (e.g. international, national, regional, and local importance);
- Sensitivity of the receptor; and
- Extent and magnitude of the impact, be it beneficial or adverse.

3.2 Definition of the Current Baseline

The baseline is defined by looking at existing environmental records for the area around the existing Hinkley Point Site and background doses received by the general population of the UK. This is discussed in more detail in Section 4.

3.3 Construction Phase Assessment

This will address the generic approach for scenarios and methods for assessing prospective dose to construction workers from potential man-made radioactive contamination present on-site during the construction phase.

3.4 Operational Phase Assessment

This section will address the human and non-human impacts for the operational phase assessment.

3.4.1 Human Impacts

3.4.1.1 Human Health Impacts, Dose Limits and Criteria

It is normal convention in the context of dose assessments to define a set of characteristics for a hypothetical group of people whose habits would result in them being subject to the highest exposure to radioactive discharges from a source (or site). The hypothetical group of people following these habits has been termed the Critical Group. This approach continues to be endorsed by the International Commission for Radiation Protection, although the term “representative person” is now used in place of Critical Group to avoid any potential misunderstanding arising from the terminology. However, since this is a relatively recent change in terminology, many of the references cited within this assessment use the phrase Critical Group, therefore the term is retained in this assessment. To determine the Critical Group for HPC and the Hinkley Point Site, an initial range of ‘candidate critical groups’ has been identified, that covers individuals with habits, (especially food consumption patterns), that might potentially result in them having the highest exposures to discharges and direct radiation. The subsequent assessments then allow those who are predicted to receive the highest dose (the Critical Group) to be identified.

Reference 2.7 of the Process and Information Document for Generic Assessment of Candidate Nuclear Power Plant Designs[22] requires a prospective dose assessment to be carried out for a generic site for the proposed nuclear new build. The dose assessment for the generic site should include:

- Prospective annual dose to the candidate critical groups exposed due to liquid discharges to the marine environment;
- Prospective annual dose to the candidate critical groups exposed due to gaseous discharges to the atmosphere;
- Prospective annual dose to the candidate critical groups exposed due to all discharges from the facility;
- Prospective annual dose from direct radiation to the most exposed member of the public;
- Identification of the Critical Group for the facility with prospective doses to the most exposed age group for the purposes of determining discharge authorisations;

- Potential short-term doses, including via the food chain, based on the maximum anticipated short-term gaseous discharges from the facility in normal operation;
- A comparison of the calculated prospective doses with the relevant dose constraints; and
- An assessment of whether the build-up of radionuclides in the local environment of the facility based on the anticipated lifetime discharges might have the potential to prejudice future legitimate uses of the land or sea.

Regulatory dose constraints for the public

Radioactive Substances (Basic Safety Standards) (England and Wales) Direction 2000 implements the obligations of the Euratom BSS[2] Directive in England and Wales. The principal aims of the Direction are to require the Environment Agencies to ensure, when exercising their duties and functions under the RSA 93 and more recently the EPRs (see Section 2.3.1).

These principles have been incorporated into the most recent Environmental Principles issued by the Environment Agency in support of their Radioactive Substances Regulation (Environment Agency, 2009)[36].

In its recent responses to the most recent recommendations of the ICRP, the UK Health Protection Agency (HPA-RPD) continues to recognise the dose constraint of 0.3 mSv y^{-1} but considers more challenging dose constraints may be applicable where appropriate. On this basis, they have proposed a dose constraint for members of the public due to new nuclear power stations of 0.15 mSv y^{-1} (HPA-RPD, 2009)[37]. Application of this to other new facilities is the subject of further consultation.

The Government has stated in the UK Strategy for Radioactive Discharges 2001-2020[38] that, as a result of reductions in radioactive discharges, there will be a progressive reduction of human exposure to ionising radiation. It is expected that members of a 'local critical group' of the general public in the UK will be exposed to a dose of no more than 0.02 mSv y^{-1} from authorised radioactive discharges to the aquatic environment from 2020 onwards. This Strategy was recently updated in July 2009 and reiterates the objective for a progressive reduction in discharges and public doses but without stating the specific dose target of 0.02 mSv y^{-1} (Department of Energy and Climate Change, 2009)[39].

In the UK Government Command Paper Cm 2919 (HMSO, 1995)[40] the Government introduced a lower bound public individual dose of 0.02 mSv y^{-1} (20 µSv y^{-1}) due to radioactive discharges. This was consistent with the Health and Safety Executive's (HSE) 1992 Safety Assessment Principles for New Nuclear Facilities. The current edition of the HSE Safety Assessment Principles for Nuclear Facilities (HSE, 2006)[41] gives a basic safety objective (BSO) of 0.02 mSv y^{-1} for any person outside a nuclear licensed site during normal operation. A BSO forms a benchmark that reflects modern nuclear safety standards and expectations.

The dose constraint of 20 µSv y^{-1} is also noted in the Interim Guidance on the Principles for the Assessment of Prospective Public doses issued by a consortium of the Environment Agency, Scottish Environment Protection Agency, Department of Environment, Northern Ireland, National Radiological Protection Board and Food Standards Agency in 2002. It is a dose below which it is stated that regulators should not seek to secure further reductions in the exposure of members of the public, provided that they are satisfied that the operator is using Best Practical Means (BPM) to limit discharges (paragraph 38 in Environment Agency, 2002)[42].

This guidance document[42] also notes widespread international agreement that doses to members of the public of the order of 0.01 mSv y^{-1} (10 µSv y^{-1}) or less are sufficiently low to be of 'no regulatory concern'. However, in paragraph 40, it notes that:

"All doses to members of the public, including those below 0.01 mSv y^{-1} remain subject to the ALARA requirement under directions placed on the Environment Agency and SEPA. This is achieved primarily through the application of best practicable means (and BAT) to limit and control authorised discharges of radioactive waste to the environment."

More recently, in 2009, DECC and the Welsh assembly government issued statutory guidance to the Environment Agency for England and Wales (DECC and Welsh Assembly, 2009)[43] with the overall objective of implementing the UK's Strategy for Radioactive Discharges[38]. With respect to the dose value of 10 µSv y^{-1} in paragraph 22, this statutory guidance states that:

"Where the prospective dose to the most exposed group of members of the public from discharges from a site at its current discharge limits is below 10 µSv y^{-1} the Environment Agency should not seek to further reduce the discharge limits that are in place, provided that the holder of the authorisation applies and continues to apply BAT".

Note that this wording suggests that the guidance applies to '*discharge limits that are in place*' but is assumed to apply equally to limits that are being applied for.

Since advice regarding the use of the 10 µSv y^{-1} (0.01 mSv y^{-1}) criterion is relatively recent, older documents and assessment statements will necessarily make comparison to a 20 µSv y^{-1} criterion. In either case, Best Available Techniques continue to apply. Hence, there is no real difference in the level of radiological protection required in seeking permission for the discharge of effluents associated with the operation of a new nuclear power station.

The table of dose criteria below (Table 1) has been taken from guidance on Principles for the Assessment of Prospective Public Doses for the Authorisation of Discharges of Radioactive Waste to the Environment published by a consortia of UK environment agencies[42], statutory guidance published by DECC and Welsh Assembly Government and recent HPA-RPD guidance (HPA-RPD, 2009)[44] and summarises these UK human dose criteria (to facilitate comparison with the small assessed doses for HPC and HP site, the regulatory dose criteria in Table 1 and subsequently, are expressed in µSv y^{-1}, units that are a thousand times smaller than mSv y^{-1}).

Radiological impacts on humans need to be assessed against the absolute values of these regulatory requirements (derived from the ICRP recommendations) and accepted or rejected as acceptable on the basis of these, with additional assessment on whether they meet the requirements of being ALARA.

Table 1: Summary of human dose criteria considered in the assessment

Criteria	Quantity µSv y^{-1}	Source of Radiation for Site Considered	
		Future Discharges	Future Direct Radiation
Dose Limit due to man-made sources (excluding medical)	1,000	✓ (& includes historic discharges)	✓
Site Constraint	500	✓	-
Source Constraint	300	✓	✓
New Build Source Constraint	150[c]	✓	✓
Screening criterion for detailed assessments.	20	✓	✓
Continued reduction in discharge limits will not be pursued, subject to demonstration of application of BAT to minimise discharges.	≤10	✓	✓

Radiological assessment due to gaseous and liquid discharges and direct radiation from HPC and the Hinkley Point Site:

On the basis of the discussions above (and Table 1) the radiological impacts to the Critical Group due to gaseous and liquid discharges and also direct radiation from the proposed HPC and the Hinkley Point site (that is HPC plus effects of HPA and HPB) are therefore assessed against the following dose criteria:

- The source dose constraint from a single new source (300 µSv y^{-1}) which applies to the dose from proposed discharges and direct radiation. Because the two EPRs at HPC will be regulated under a single permit under the Environmental Permitting Regulations[19], together, they constitute a single new source[d].
- The site dose constraint (500 µSv y^{-1}) which applies to the cumulative dose from the discharges from all sources at a single location (but direct radiation is not included). Together, the Hinkley Point A and B reactors and

[c] New source constraint of 150 µSv y^{-1} is based on recent HPA-RPD Guidance, (HPA-RPD, 2009)[44]
[d] The EA interim guidance on prospective doses states that a single new source be defined as "*a facility or group of facilities which can be optimised as an integrated whole in terms of radioactive disposals*" The two UK EPRs at HPC can be considered to meet this requirement.

the proposed HPC EPRs will form a contiguous set of site operations and therefore constitute a single site[e].

For impacts due to HPC discharges, there is also assessment against the 10 µSv y^{-1} criterion, below which the UK Government states that the Environment Agency should not seek to further reduce the discharge limits that are in place, provided that the holder of the authorisation applies and continues to apply BAT[42].

In the discussion of the results, the prospective doses for HPC are also compared against baseline doses resulting from natural and man-made background sources that constitute both voluntary and involuntary sources of exposure.

Future potential public doses due to build-up are assessed against a range of criteria, including the local terrestrial background and those relevant to radiological protection objectives for contaminated land. Those to the public and due to radioactive materials in soil and water that may arise in the HPC construction phase are assessed against relevant standards, in particular the Radioactive Substances Act[18] and UK drinking water standards (World Health Organisation, 2004[45], European Union, 1998[46], SI, 1998[47]) although there is no intention that water from the site should be used for the supply of drinking water.

Radiological impacts from transport

Construction and operation of the HPC EPR will involve transport of some radioactive materials by road and rail for which a specific dose assessment has been carried out. The doses are due to direct radiation (or “shine”) from the conveyance. The relevant limit against which these doses can be assessed is the public dose limit of 1,000 µSv y^{-1} as given in IRR99[16].

Collective dose assessment criteria

There is no legal dose limit on collective doses. However, the International Atomic Energy Agency presented dose criteria which are considered sufficiently low that doses arising from sources or practices that meet these criteria may be exempted from regulatory control. One of these criteria is that collective dose should be less than about 1 man Sv per year of practice (paragraph 145 in Environment Agency

[e] Note that in earlier issues of this EIA Technical Note a matrix of impacts using the above dose criteria and analogous to that applied in the other EIA Technical Notes (viz ‘minor’, ‘major, ‘negligible’) was established. The dose criteria for humans (above) are not, however amenable to this form of impact classification and for this reason, radiological impacts are based on whether they remain below the constraints given above (site or source) with consideration of additional guidelines (notably 10 µSv y^{-1}) where applicable, plus assessment against other man-made sources of exposure.

principles for assessment of public doses[42]). For a nuclear power station, a year of practice may be taken to be equivalent to a year of routine continuous operation[f].

The EA interim guidance document for the assessment of prospective public doses principles[42] (paragraph 152) states that for collective doses:

"*Calculated average annual individual doses for a population group (doses per head of population or per caput doses) in the nanosievert (nSv y^{-1} of discharge) range or below should be ignored in the decision making process as the associated risks are 'miniscule' and the contribution to total doses to individuals will be insignificant. Higher annual doses, up to say a few microsieverts (µSv y^{-1} of discharge) can be considered 'trivial' but may require some consideration particularly if at the higher end of the range. Calculated annual average individual doses in excess of these values should prompt careful consideration of the discharge options being considered*".

In guidance by the European Commission (European Commission, 2007)[48] it is stated that per caput individual doses of less 10^{-5} Sv represent a 'trivial' level of individual risk. 10^{-5} Sv is equivalent to 10 µSv and therefore consistent with 'a few microsieverts' (above).

Note that the terms 'miniscule' and 'trivial' used in the subsequent assessments are those used in the guidance quoted above. Collective doses are also compared with those from industry as a whole and those due to C-14 to the dose from this naturally occurring long-lived radionuclide.

Short-term releases

The EA interim guidance document for the assessment of prospective public doses principles[42] (paragraph 142) states that short-term releases should be compared with the source constraint (300 µSv y^{-1}) and the public dose limit (1,000 µSv y^{-1}) taking into account other relevant contributions.

Total dose

The Total Dose assessed dose includes that from HPA and HPB (assuming discharges at their authorised limits) plus that from HPC and that from historic man-made off-site sources. It is compared with the dose limit for members of public (1,000 µSv y^{-1}) which includes all man made sources of radiation but excludes direct medical exposures.

[f] There is no question here of claiming that, if collective dose is below 1 Man Sv y^{-1}, discharges should be considered as outside regulatory control. The 1 Man Sv y^{-1} collective dose is simply a useful guideline from the relevant Environment Agency guidance on the assessment of public doses.

3.4.1.2 Specific Assessment Methodology for Impacts During Operation – Continuous releases

In order to determine the significance of the radiological impact of HPC discharges it is necessary to assess the dose uptake from these releases by critically exposed members of public and non-human species populations in the local vicinity. The methods for assessing doses to human and non-human populations are described in the sections below.

Initial Radiological Assessment Methodology – for Human Impacts

The Environment Agency has provided a methodology for carrying out an Initial Radiological Assessment or IRA (Environment Agency, 2006)[49]. This methodology document consists of two parts: A user report containing an overview of the methodology and tables of "dose per unit release" (DPUR[g]) for a large number of radionuclides; and a methods and input data report.

The purpose and scope of the initial assessment methodology is to provide a system for undertaking an initial cautious prospective assessment of the dose arising from sources of radioactive discharges to the environment, and to identify those sources of discharges for which a more detailed assessment should be undertaken. The assessment consists of up to three stages:

- In the first stage the Initial Radiological Assessment is carried out using default data as defined in the IRA methodology. If the assessed dose is greater than 20 µSv y^{-1} then a Stage 2 Assessment must be completed;

- A Stage 2 Assessment uses refined data, as defined in the IRA methodology, which is more suited to the site in question. Again, if assessed doses are greater than 20 µSv y^{-1} then a Stage 3 Assessment must also be completed;

- A Stage 3 Assessment is a separate site-specific assessment.

Completion of an IRA assessment in application for authorisation (and any future permit) to discharge is deemed to be sufficient by the Environment Agency, providing the relevant assessment stages have been completed.

Exposure Groups and Pathways Considered (IRA Methodology)

In the Initial Radiological Assessment (IRA) the Environment Agency states that if direct radiation exposure of the public from sources on a site is known to occur, an

[g] In Calculating the DPURs, discharges are assumed to be continuous, uniform routine releases that continue for 50 years. Dose assessment calculations are carried out at the 50th year.

assessment of direct radiation dose should be made. The IRA identifies two local candidate critical groups for assessment. These are:

- Releases to Air - Local Resident Farming family; and
- Releases to Coastal Water – Fisherman family.

Stage 1 IRA using Default Data – as calculated for Generic Design Assessment (GDA)

A Stage 1 IRA was completed for a single EPR unit as part of the Pre-Construction Environment Report (PCER) for the UK-EPR design. The stage one assessment used unmodified DPUR values. In the GDA, results are presented in Chapter 11 of the PCER document[50]. Using the generic stage 1 assumptions, doses were greater than 20 µSv y^{-1} and therefore a Stage 2 assessment was completed.

Stage 2 IRA using Refined Data - as calculated for GDA

A Stage 2 IRA was completed for a single EPR unit as part of the PCER for the UK-EPR design. Here an effective stack height of 30m and a local marine compartment volumetric exchange rate of 126 $m^3 s^{-1}$ (representing the lowest exchange rate of the existing UK reactor sites) were assumed for the revised calculations. All other assumptions and parameters remained unchanged from the Stage 1 assessment. As the discharge point for the liquid discharges was assumed to be close to the site (within a few hundred metres) it was necessary to combine the results for the two exposure groups as both exposure groups could be exposed to both releases.

The results of the Stage 2 assessment for a single EPR showed doses above the dose of 20 µSv y^{-1} so that a Stage 3 detailed site specific assessment was necessary.

Stage 3 'envelope site' IRA - as calculated for GDA

The Stage 3 'site specific' GDA assessment defined an envelope site derived from the most conservative characteristics of the environment around existing UK nuclear sites under consideration for future EPR reactors. PC CREAM 98 (Mayall, 1997)[51] was used to calculate individual doses from routine releases. The Stage 3 critical group (all discharges) doses for the generic site for a single EPR reactor were calculated to be 21, 9.1 and 9.3 µSv y^{-1} to adults, children and infants respectively.

As the Stage 2 IRA assessment, when completed for the GDA, resulted in doses greater than 20 µSv y^{-1}, a detailed site specific assessment has been completed for HPC (EPR East and EPR West). The general methodology for this is introduced below and discussed in more detail in Section 5.2.

Hinkley Point Site-Specific Assessment Methodology for Impacts on Humans

This section presents a summary of the methodology used for the assessment of the impact on the human population of Hinkley Point C discharges. The same method has been used to assess doses from HPA and HPB reactor discharges in order to determine the cumulative dose from the Hinkley Point Site. These methods are consistent with the general methods developed for the GDA.

HPA and HPB and the proposed HPC are assumed to discharge into the local marine compartment and the local terrestrial environment and give rise to exposures via the same exposure pathways. Discharges for each source were modelled separately and in combination in order to produce results for each source and to give a cumulative predicted dose for the entire Hinkley Point Site. Cumulative doses and impacts and assessment against dose criteria are discussed in Section 7.

Assessment methodologies have been developed to assess the impacts from a number of scenarios. These are for:

- The assessment of individual doses as a result of continuous releases of gaseous and liquid discharges to the environment;
- The assessment of direct dose;
- Annual dose assessment of the critical group;
- The assessment of collective doses;
- The assessment of individual doses as a result of short-term gaseous releases to the environment, and
- The assessment of individual doses as a result of build-up of radioactive materials in the environment.

Details of each methodology, parameters and results of calculations undertaken to determine the effect that routine and planned radioactive discharges may have on the surrounding human population at Hinkley Point are presented in Section 5.2.

Methodology for the Prediction of Dispersion of Gaseous Discharges from the Proposed Site

The EPR stack height is determined by different design criteria such as civil engineering, environmental (atmospheric dispersion and associated ground deposition) and impacts on the visual landscape. For atmospheric dispersion, the ADMS dispersion model was used to predict dispersion factors for routine releases for a range of possible stack heights (CERC, 2007)[52].The stack height must, at a minimum, be equal to the height of the UK EPR Reactor Building (60 m) and modelling has shown that at stack heights more than 70 m, the dispersion and deposition factors do not decrease significantly. The established heights of the stacks on each EPR are 70 m and form the basis of establishing the impacts of gaseous radioactive discharges from each of the HPC EPRs in the current assessment.

The ADMS model takes account of plume rise and building wake on the discharges from the stack. However, in PC CREAM 98 (used to calculate doses) these factors are not included and the input parameter required is the effective, not actual, stack height. The 2/3rd reduction method is used for estimating this. It results in an effective stack height of 23.3 m. This method equates to using a conservative assumption for the EPR stack height for the purposes of estimating impacts of gaseous radioactive discharges. Further details of input parameters are given in Section 5.2.

Methodology for the Assessment of Individual Doses as a Result of Continuous Releases to the Environment

In order to complete an assessment of dose to members of the public, it is necessary to determine which individuals would have the highest exposure to each of the sources of radioactivity. To do this, an initial range of 'candidate critical groups' is identified, that covers individuals with habits (especially food consumption patterns) that might potentially result in their receiving the highest exposure to discharges and direct radiation. The subsequent assessments then allow those who are predicted to receive the highest dose, the Critical Group, to be identified.

Two sources of information are available to aid the generation of habitat data and food intake patterns that lead to ingestion dose. The 2006 CEFAS report covers a survey conducted around Hinkley point in 2006 and is based on food consumption rates and occupancy factors taken from raw data (CEFAS, 2007)[53] . More generalised patterns are available from an NRPB report NRPB-W41 (Smith, 2003)[54]. The CEFAS report represents more local specific data and a previous review suggested it also gives more conservative consumption patterns. In order to perform a Hinkley Point specific assessment, local data from the CEFAS report are therefore preferred, whenever possible. Details of the input data and calculations based on this source are given in the sections below.

The dwelling where airborne and deposited activity concentrations would be highest (of all local dwellings) for HPC discharges[h] has been used as the receptor location, in combination with the generalised critical group habit data from the CEFAS[53] study data, to create a hypothetical critical group, members of which

[h] The critical group dwelling selected for HPC is not the point of highest concentration for HPA or HPB discharges. However, in order to determine a baseline, and to complete a cumulative dose assessment for HPC, it was necessary to select a single receptor point for atmospheric discharges. As this is an assessment to determine the impact of HPC discharges, the receptor location that could give the highest exposures for HPC discharges has been selected.

would receive the highest potential dose due to gaseous discharges from HPC to the atmosphere.

There is evidence in the CEFAS[53] report for Hinkley Point of commercial fishing activities and subsequent consumption of catches in the village of Stolford, to the west of the HPB reactor site. These critical habit pathways were used to determine the hypothetical persons most exposed to marine discharges based on critical exposure and ingestion rates given in CEFAS[53].

These two hypothetical resident human receptor groups were then used as the basis for determining two candidate critical groups exposed to all HPC discharges:

i. It was assumed that a farming family living near the coast could be exposed to gaseous discharges through the terrestrial pathways of: a) ingestion of contaminated foodstuffs grown on the farm; b) inhalation of and external exposure to the plume and deposited radionuclides. The two foodstuffs[i] contributing the highest fraction of dose were assumed to be consumed at critical (97.5th percentile of all CEFAS observations for these food group) rates[j], and all other foodstuffs were assumed to be consumed at average rates (mean of all CEFAS observations for these food groups). This is known as the "Top Two" method. It ensures a realistically conservative estimate of ingestion dose and is consistent with the GDA study[50] method and other studies of this nature. It is also assumed they could be exposed to marine discharges through the marine pathways of ingestion of locally sourced seafood, external exposure to beach sediments and inhalation of sea-spray when spending recreational time on a local beach. Average (mean) consumption rates of fish and shell fish and recreational activity times were taken from the CEFAS[53] study to determine marine exposures to this 'Farming Family'. This candidate critical group is therefore referred to as the **'Farming Family with marine and gaseous exposure'**.

ii. It was assumed that a fishing family - exposed to liquid discharges through contact with contaminated fishing gear (adults only) and beach sediments, from ingestion of seafoods (at 97.5th percentile rates of all CEFAS observations for seafish, crustacea and mollusca) caught in the area and inhalation of sea-spray could live locally and would therefore be exposed to the same terrestrial pathways as the 'Farming Family' (item i. above). It was conservatively assumed that this family might live at the same location as the 'Farming Family with marine and gaseous exposures' (item i above) and thus also be exposed to the

[i] CEFAS labelled terrestrial foodstuffs were grouped as follows: green vegetables and other vegetables as green vegetables; root vegetables and potato as root vegetables; domestic fruit and wild/free fruits as fruit; milk as milk; butter, cream cheese and yoghurts as milk products; cattle meat as cattle meat and sheep meat as sheep meat.

[j] In order to determine the top two foodstuffs, an assessment was completed assuming all foodstuffs were consumed at critical (97.5th percentile) rates. The two foodstuffs that contributed the highest doses were then taken forward to be the top two foodstuffs. These were: root vegetables and milk for adults; and milk products and milk for children and infants.

‘highest’ airborne and deposited activity concentrations from gaseous discharges from HPC. It was also assumed that they would consume locally grown produce at average (mean of all CEFAS[53] observations for each terrestrial food group) rates. This candidate critical group is therefore referred to as the **‘Fishing Family with marine and gaseous exposure’**.

In each case, individual doses were calculated for three age groups: adult; a 10 year old child, and a 1 year old infant. Further details of the exposure routes and consumption patterns for these two candidate critical groups are given in Section 5.2.2.

The Health Protection Agency has provided recommendations on the in-utero exposure of the embryo and foetus. These recommendations state that in many exposure situations the explicit assessment of the dose to the embryo/foetus is not required. However, for the radionuclides P-32, P-33, Ca-45 and Sr-89 it is recommended that an assessment is made. As these radionuclides do not form part of the spectrum of radionuclides considered in this report or reported in EPR discharges (or in those from site facilities such as any proposed Interim Storage Facility for Spent Fuel) the dose to the embryo/foetus is not considered further.

The annual dose to the candidate critical groups due to gaseous discharges from HPC to the atmosphere (and HPA and HPB for the cumulative assessment) was assessed using the PLUME and ASSESSOR modules of PC CREAM 98[51].

The annual dose to the candidate critical groups from liquid discharges was assessed using the DORIS and ASSESSOR modules of the PC CREAM 98 suite.

Where non-standard radionuclides were assessed, e.g. Co-58, data was required to be generated using the GRANIS, RESUS and FARMLAND modules for use by PC CREAM in the ASSESSOR module.

3.4.1.3 Methodology for the Assessment of Direct Exposure of Humans Off-Site

Direct exposure to radiation (that is radiation ‘shine’) from the reactor building for members of the public will be negligible, as the shielding present will ensure contact dose rates for the building are below limits of detection, and would not be measurable at the site boundary.

Exposure to direct radiation from Intermediate Level Radioactive Waste (ILW) and any Spent Fuel stores serving the HPC EPRs will give the greatest direct radiation dose for a member of the public from HPC facilities. In the UK, assessments of direct radiation are usually carried out by monitoring radiation levels at the site boundary and at the nearest habitation. Estimates of direct radiation exposure for HPA and HPB are provided in Table A4.1 of Radioactivity in Food and the Environment (RIFE) 13[55]. A direct radiation dose of 0.004 mSv y^{-1} is given for local residents living within 1 km of the existing Hinkley Point Site.

The detailed design for the storage of spent fuel and ILW at HPC has not yet been finalised, and therefore building shielding and inventories are not available. Therefore, in order to complete a direct radiation assessment, basic assumptions have been made to determine source term characteristics. The methodology is discussed in Section 5.2.2.5. The doses were then added to those due to discharges and compared with the assessment criteria (notably source constraint) established in Section 3.4.1.1.

3.4.1.4 Collective Dose Resulting from Discharges

Collective doses from gaseous and liquid discharges were calculated using PC CREAM[51]. Grid data around the site and beyond are already defined for in-built sites in PC CREAM – including the existing HPA and B reactor sites. Population and agricultural product distribution within the European Community is provided for each site within the PC CREAM database, as is the regional marine compartment into which the discharge is released. This provides data on total annual food production in each annular segment of a polar grid centred on the site of interest and extending to cover the area of interest. Individual external and inhalation doses in each annular segment of the polar grid are scaled by the population in that segment.

For aerial discharges, PC CREAM requires an effective stack height. The effective stack height takes into account effects such as plume rise and building wake. Using the 2/3 reduction technique[56] for estimating effective stack height as a result of building wake effects from the UK EPR reactors at Hinkley Point would give an effective stack height of 23.3 m for a 70 m stack (Section 3.4.1.2).

Collective doses per year of discharge were truncated at 500 years as required by the Environment Agency in the PID[22]. The population groups to be considered are the UK, Europe and World.

It is possible to obtain an estimation of average individual doses ('per caput') for populations calculated in the collective dose assessment. This allows collective dose to be compared with collective dose guidance (Section 3.4.1.1) and link this calculation with design considerations. The population data for UK, Europe and World were assumed to be 55 million, 700 million and 10 billion respectively as these are the values used by PC CREAM 98[51] to estimate collective doses.

3.4.1.5 Potential Doses Resulting from Short-Term Gaseous Discharges

The prospective doses to three age groups in an off-site location have been calculated for a single short-term gaseous discharge (consisting of a monthly inventory) within 24 hours from a single EPR stack. Separate calculations were undertaken for potential single discharges from the EPR East (C1) and the EPR West (C2) stacks. The pattern of nuclides released was the same as for normal operational discharges, but with an altered ratio of isotopes to specifically reflect the source term associated with these short-term release events.

Potential short-term doses, including via the food chain are calculated for a local critical group based on the methods described in NRPB-W54 (Smith, 2004) [57]. This critical group was based on occupancy at a receptor point at which the highest 95th percentile air concentration and ground deposition rate is predicted to occur. The doses were then compared with the short-term assessment criteria established in Section 3.4.1.1.

Aqueous liquids, after treatment and testing, are stored in holding tanks prior to discharge into the main once-through sea water cooling discharge. Liquid discharges are therefore short-term discharges that occur throughout the year and flow into a continuous discharge route. They are therefore only modelled as continuous releases according to the methods in section 3.4.1.2.

3.4.1.6 Build-up of Nuclides in the Environment due to Discharges

The Environment Agency has highlighted that at the end of the life of any power station, the land may not be able to return to free and unrestricted use due to potential build-up of radionuclides. Currently in the UK, Article 53 of the Council Directive 96/29/EURATOM is enacted in the Radioactive Contaminated Land Regulations 2008 (SI, 2008)[58].

Build-up refers to the accumulation of radionuclides in environmental media due to discharges. It accounts for the effects of gradual accumulation of radionuclides in the environment over the operating life of a nuclear plant. A range of potential groups may then be exposed to these sources (see below).

In order to calculate activity concentrations in soil, activity concentrations in air must be calculated. The location of highest concentration outside the site boundary was determined to be 427 m from the Eastern HPC stack (C1) at a bearing of 105°. Activity concentrations in soil have been estimated using the FARMLAND module of PC CREAM.

In order to calculate activity concentrations in seawater and on the local beach, the DORIS module was used. The significance of the impact of the build-up of radioactivity will depend on the future use of the land and activities in the sea.

The doses associated with the potential build-up of radionuclides on land can be assessed using the methodology as described in NRPB-W36 (Oatway, 2003)[59] together with the activity concentrations as described above. NRPB-W36[59] provides a methodology for estimating doses to members of the public from future use of land previously contaminated with radioactivity. This report includes tables of doses per unit contamination for a number of possible use scenarios for the land for a range of radionuclides.

The dominant scenario for those radionuclides listed above, which are included in the NRPB-W36[59] assessments, is exposure during construction. This scenario was used for assessing doses to members of the public from future construction on land adjacent to the Hinkley Point Site following shutdown of the Hinkley Point EPR reactors. The construction scenario is discussed in Appendix D of NRPB-W36[59].

A review of potential uses of the sea has been carried out based on uses discussed in the CEFAS[53] study. Scenarios where occupancies are high and/or intakes of radionuclides occur will give the highest doses. Potential uses included:

- Water sports;
- Beach combing/walking;
- Hobby fishing (including consumption of catches);
- Commercial fishing, and
- Houseboat dwelling.

3.4.1.7 Transport of Radioactive Materials for HPC

It will be necessary to transport radioactive materials to and from a reactor site throughout its operational lifetime. Radioactive materials generally consist of sources for non-destructive testing (NDT) of plant and shielding, new and spent fuel, contaminated and activated materials and operational solid wastes. During transport, members of public may be externally exposed to the consignment as a result of direct radiation. The scenarios of exposure considered are discussed in Section 5.2.4.

3.4.2 Non-Human Impacts

The following describes the methodology for assessing radiological impacts on non-human species. This requires assessment of the dose and judgement as to the value and sensitivity of the habitats/species affected (in contrast to humans, for which universal accepted value of a life is applicable).

3.4.2.1 Dose Constraints (Non-Human Species)

US DoE Approach

The United States Department of the Environment (DoE) has produced a report *A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota (*Domoter, 2000*)*[60]. This report provides methods, models and guidance for evaluating doses from ionising radiation to populations of aquatic animals, terrestrial plants and terrestrial animals using a graded approach. This recommends a dose threshold of 10 mGy d^{-1} for aquatic animals and terrestrial plants, and 1 mGy d^{-1} for terrestrial animals. This gives an equivalent hourly dose rate of 400 µGy h^{-1} for aquatic animals and terrestrial plants and 40 µGy h^{-1} for terrestrial animals. The DoE graded approach consists of a screening method followed by three more detailed levels of analysis if necessary. The screening method employs “Biota Concentration Guides”. These are conservative limiting concentrations of radionuclides in soil, sediment or water that would not cause these dose limits for the protection of populations of aquatic and terrestrial biota to be exceeded.

ICRP Guidance for Non-Human Species

The publication ICRP 91[5] proposes a framework which would work as a practical tool to provide high-level advice for regulators and operators. This report is just a first stage in developing an international tool for assessing the impact of ionising radiation on non-human species.

The 2007 Recommendations of the ICRP[3] do not give any criteria for determining environmental effects of radioactivity. They are in the process of developing reference animals and plants in order to develop recommendations for the protection of other species. National legislation is driven by ICRP recommendations.

Dose Criteria for Non-Human Species

A general conclusion of the 1992 IAEA technical report *Effects of Ionizing Radiation on Plants and Animals at Level Implied by Current Radiation Protection Standards* (IAEA, 1992)[61] was that there is no convincing evidence that chronic radiation dose rates below 1 mGy d^{-1} will harm animal or plant populations. This gives an equivalent hourly dose rate of 40 µGy h^{-1}.

The Environment Agency Report R&D 128[27] previously concluded that it is unlikely that there will be any significant effects in populations of freshwater and coastal organisms at chronic dose rates below 400 µGy h^{-1}; terrestrial plant populations at chronic dose rates below 400 µGy h^{-1}; and terrestrial animal populations at chronic dose rates below 40 µGy h^{-1}.

More recently, the Environment Agency (EA, 2010)[62] recommends that for non-human species, worst case dose rates should be estimated assuming the presence of reference organisms for the relevant ecosystem at the position of maximum environmental concentration due to discharges (usually close to the site boundary for the terrestrial ecosystem and close to the discharge for aquatic ecosystems). The calculated dose rates on all non-human species should then be assessed against a guideline value of 40 µGy h^{-1}.

The computer modelling code ERICA (Beresford, 2007)[28] and associated radiological effects database FREDERICA (Copplestone, 2008)[63] are EU funded assessment tools for predicting the dose and effects on non-human species from radioactivity in the environment. The ERICA default screening dose rate is 10 µGy h^{-1}. Therefore, assessments falling below this screening level would cause no measurable harm to non-human species. This bounds the Environment Agency requirements (above) and provides a more stringent value against which to carry out assessments of radiation impacts on non-human species.

Magnitude of Non-Human Radiological Impacts

Radiological impacts on non-human species, unlike those on humans, have no absolute regulatory or universal ‘value’. This is because different non-human species or their habitats have different perceived values depending on, for example, their rarity, sensitivity or location. There is therefore a need to consider these aspects of the species or habitat affected and draw a judgement on the radiological impact. The following sections provide an outline of the bases on which this was done:

Value and Sensitivity

The value and sensitivity of the receptor will be a function of a variety of factors e.g. biodiversity value, social / community value and economic value. The value or potential value of a resource or feature can be determined within a defined geographical context. The following hierarchy is recommended by IEMA (2006)[33]:

- International;
- UK;
- National (i.e. England/Northern Ireland/Scotland/Wales);
- Regional;
- County (or Metropolitan e.g. in London);
- District (or Unitary Authority, City or Borough);
- Local or Parish; and
- Within zone of influence (only might be the project site or a larger area).

Designated Sites

Some receptors have already been assigned a level of conservation value through designation. Internationally important sites include: Special Areas of Conservation (SACs), Special Protection Areas (SPAs) and Ramsar sites. Candidate SACs, potential SPAs and proposed Ramsar sites should be given the same consideration as designated sites. Nationally important sites are designated as Sites of Special Scientific Interest (SSSI) in England, Scotland and Wales or as Areas of Special Scientific Interest (ASSI) in Northern Ireland. They may also be designated as National Nature Reserves. Local Authorities and The Wildlife Trusts have designated sites that are recognised as of importance at regional / county, district / borough, etc., levels. Whilst a variety of terms are used to describe these sites, they are now generally referred to collectively as Local Sites.

Where a feature has value at more than one level, its overriding value is that of the highest level. For example, a site designated both as an SPA for internationally important features and as an SSSI for nationally importance features should be considered as being internationally important. The features for which the site has been designated at each level may differ and should be valued accordingly. Features of the site that are not the reasons for its designation(s) should be assessed and valued according to their intrinsic value.

Secondary or Supporting Value

Some features or receptors that are currently of no particular interest in themselves may nevertheless perform an important environmental function, e.g. because they act as a buffer against negative impacts, or because they enable in some other way the effective conservation of a more valuable feature. For example, an area of scrub may be included in calcareous grassland SSSI to act as a buffer from agricultural spraying on adjoining farmland. In this instance, the scrub performs an important ecological function in protecting a feature of national importance.

People derive benefits from the environment in various ways, including:

- Formal recreational enjoyment;
- Health aspects;
- Informal recreational activity, e.g. countryside walks; and
- Use of habitat areas for the purpose of learning about wildlife.

Economic implications may result from impacts on certain ecological features and resources that are financially valuable, for example:

- Populations of cyprinid fish for angling;
- Populations of shell fish in estuaries;
- Rare breeding birds at publicly accessible breeding sites that attract large numbers of visitors, who bring economic benefits to the local economy; and
- Green space might play a valuable role in contributing to the health and wellbeing of local communities with consequent economic benefits.

Sensitivity is based on the assessment of intolerance against a benchmark level of change in an environmental factor, and the likely recoverability of the species population or biotope. In order to help define the level of 'Value and Sensitivity', the guidance in Table 2 has been adopted and is based loosely on the example given in (Scottish Natural Heritage, 2006)[64].

Table 2: Guidelines for the assessment of value and sensitivity

Value and Sensitivity	Guidelines
High	Feature/receptor possesses key characteristics which contribute significantly to the distinctiveness, rarity and character of the site / receptor e.g. Designated features of International / National designation / importance e.g., SSSI, Ramsar etc and receptor is identified as having very low capacity to accommodate proposed form of change i.e. is very highly sensitive. Feature / receptor possess very significant biodiversity, social/community value and / or economic value. Feature / receptor is extremely rare.

Table contd./

Value and Sensitivity	Guidelines
Medium	Feature/receptor possesses key characteristics which contribute significantly to the distinctiveness, and character of the site / receptor type e.g. Designated features of International / National designation / importance e.g., SSSI, Ramsar etc. and receptor is identified as having low capacity to accommodate proposed form of change i.e. is highly sensitive. Feature / receptor possess significant biodiversity, social / community value and / or economic value. Feature / receptor is rare.
Low	Feature/receptor only possesses characteristics which are locally significant. Feature/receptor not designated or only designated at a local level. Feature / receptor identified as having some tolerance of the proposed change subject to design and mitigation etc i.e. is only moderately sensitive. Feature/receptor possesses moderate biodiversity, social / community value and / or economic value. Feature / receptor is relatively common.
Very Low	Feature / receptor characteristics do not make a significant contribution to the character or distinctiveness locally. Feature / receptor not designated. Feature / receptor identified as being generally tolerant of the proposed change i.e. of low sensitivity. Feature / receptor possess low biodiversity, social/community value and / or economic value. Feature / receptor is common.

3.4.2.2 Non-Human Species Radiological Assessment Methodology

The methodologies used for calculating dose to non-human species were EA Research and Development report R&D 128[27] and the EC Software ERICA[28]. These assessments deal with a range of generic habitats each containing a selection of generic species at different trophic levels. For the current assessment, the ERICA models were refined to accommodate site or locality specific species, notably badgers and bats. The additional requirements to accommodate these are due to their size, and habits. Once the initial radiological assessments were completed (based on the criteria in Section 3.4.2.1) judgements of sensitivity and species/habitat values were made to establish the magnitude of the final impacts.

The assessment for non-human species, like that for humans, requires selection of specific locations that should reflect, as far as possible, those where maximum doses will be received and also that cover a range of habitat types. For the current assessment, four habitats were selected representing terrestrial, marine, freshwater and coastal environments. The locations of these are shown in Figure 4 with further descriptive details in Section 5.2.3. The habitats will include all of the generic species covered in the EA R&D 128[27] and ERICA[28] methodologies plus the site-specific species of badgers and bats.

R&D 128[27]

R&D 128 describes the behaviour and transport of radionuclides in the terrestrial, coastal and freshwater environment and considers the impact of ionising radiation on wildlife in these environments. The report also makes recommendations on an approach for the impact assessment of ionising radiation on wildlife in England and Wales. Dose per unit concentration is calculated for a range of nuclides and for a number of species, based on a basic model for their size, uptake of radionuclides and external exposure in the environment. The dose calculations have been created on several spreadsheets which can be manipulated to use default values, modelled or measured concentrations in the different species or ecosystem compartments. This report was produced as an interim measure until European and International frameworks were developed.

***ERICA*[28]**

The ERICA[28] programme, funded by the European Commission was released in 2007. The ERICA Integrated Approach guides a user through developing the scenario, performing an impact assessment and evaluating the data produced. The ERICA assessment consists of three tiers:

- An initial Tier 1 screening assessment where, if the pass criteria are met, the user can exit the assessment process;

- A Tier 2 where more site-specific parameters can be used; and finally,

- A Tier 3 which consists of a probabilistic risk assessment and is used when the screening dose criteria are exceeded at Tiers 1 and 2.

ERICA recommends a default screening dose rate of 10 µGy h^{-1} based on chronic exposure data from the FREDERICA[63] database. The screening dose rate is used to calculate a risk quotient. This gives a numeric value to the level of risk. The risk quotient has a value of 1 if the assessed dose equals 10 µGy h^{-1}. It is intended that this will eventually replace the approach in R&D 128[27].

ERICA is unable to calculate doses to non-human species from noble gases. Therefore both ERICA and R&D128 have been used in the current non-human radiological impact assessments. This additional noble gas assessment was not completed during the GDA phase assessment nor was an assessment of dose to non-human species in a freshwater environment. The current Hinkley Point C Site assessment is therefore a progression of these studies.

3.5 Mitigation Measures

Once the impacts have been evaluated and their significance determined, mitigation measures are proposed which are designed to prevent and minimise all impacts. There are several options of mitigation:

- Prevention: Avoid, relocate, modify the design and/or do not carry out the development;

- Minimisation: Modify location, modify design, alter technology, reduce size and scale of development;

- Compensation / Remediation: Provide replacement elements for any lost environmental elements (e.g. open green spaces, public facilities, wildlife area etc) / habitat. When adverse impacts are unavoidable, it may be possible to limit the duration of an impact by undertaking remedial works. For example, the impact of mineral extraction on the landscape is largely unavoidable, but following the completion of extraction ,the affected land can be restored to complement or enhance the character of the landscape; and

- Enhancement: In addition to reducing the adverse impacts of a project, many proposals provide the opportunity for environmental improvement. Enhancement / net benefit / new benefit is the genuine enhancement of the environmental interest of a site or area because adverse impacts are limited in scope and scale, and the project includes improved management or new habitats or features, which are better than the prospective management, or the habitats or features present there now. This is particularly true for projects that may be located on brown field or contaminated sites. However, it should be borne in mind that enhancement cannot be insisted upon.

The preferred hierarchy of mitigation is prevention first, then minimisation and only as a last resort, compensation / remediation. The aim in all mitigation proposals is to reduce any significantly adverse impacts to acceptable levels. The purpose of mitigation measures is to limit, not necessarily to eliminate, the environmental impacts of the development.

3.6 Residual Impacts

The final step in the EIA process is the assessment of the residual impacts after the implementation (where necessary) of the proposed mitigation measures for the HPC UK EPRs. These are considered in Section 8.

3.7 Limitations and Assumptions

At the time of writing the current issue of the EIA Technical Note, some limitations and assumptions have been identified as follows:

- Construction and operational phase designs and plans for the HPC site are still in development, and have therefore not been finalised. It is considered unlikely, however, that the subsequent assessment of finalised design details will result in any significant changes to the conclusions drawn from the current radiological assessment.

- Further information on uncertainties in the methods used in the radiological assessments is given in Section 9.0.

4.0 BASELINE ENVIRONMENTAL CHARACTERISTICS

4.1 Sources of Radiation Exposure in the UK

All individuals in the UK are exposed to ionising radiation to a varying degree from natural and anthropogenic sources. The 2005 review of ionising radiation in the UK by the Health Protection Agency (HPA-RPD 2005[65]) evaluated the magnitude of exposure in the UK to ionising radiation. This document estimates individual doses based predominantly on data collected for the years 2001 to 2003.

The summated average annual dose to one individual was 2,700 μSv y^{-1}. A breakdown of the contribution of sources of ionising radiation to annual collective dose and average annual dose is provided in Table 3 below and graphically in Figure 5:

Table 3: Annual exposure of the UK population from all sources of ionising radiation[65].

Source	Annual collective dose (Man Sv)	Average individual annual dose (μSv)
Natural:		
Cosmic	19,400	330*
Gamma	20,600	350
Internal	14,700	250
Radon	76,400	1,300
Man-made:		
Medical	24,300	410
Occupational	385	6
Fallout	350	6
Disposals	50	0.9
Consumer products	4	0.1
Sum (rounded)	157,000 Man Sv	2,700 μSv^{-1}
*Includes 30 μSv from air travel		

Natural sources contribute significantly more to the annual dose than artificial sources. Natural sources contribute on average 2,230 μSv y^{-1}, which is about 84% of the summated annual individual dose. Within the natural sources of exposure, radon is by far the largest contributor and contributes on average 1,300 μSv y^{-1}, which is around 48% of the average annual dose. However, the dose from radon can vary widely with geographical location. Figure 6, taken from the Indicative Atlas of Radon in England and Wales (Miles et al, 2007)[66] shows that the Hinkley Point area is not one of concern for radon. The annual local dose from this natural source will therefore be below the UK average of 1,300 μSv y^{-1}. Other pathways of natural contribution to annual dose include cosmic radiation contributing on average 330 μSv y^{-1} (12% of the average annual dose). Gamma radiation from soils and other natural materials contribute on average 350 μSv y^{-1} (13% of the average annual dose). Internal sources due to intakes of radionuclides in foodstuffs and measured levels of naturally occurring K-40 in the body (for adults) contribute on average 250 μSv y^{-1} (9% of the average annual dose).

The cosmic radiation dose can also vary significantly from one individual to the next mainly due to the large increase in the amount of cosmic radiation experienced during any air travel. A long haul flight from London to Sydney will add 160 μSv per return journey and a short haul flight from London to Glasgow will add 6 μSv and London to Malaga will add 15 μSv. The average annual dose contribution from air travel is around 30 μSv y^{-1} which is about 9% of the overall average annual cosmic radiation dose of 330 μSv y^{-1}.

The highest anthropogenic contributor to dose is that due to medical exposures. This contribution has increased in recent years due to increased use of computed X-ray tomography and the number of nuclear medicine procedures performed. An intra-oral dental x-ray results in a dose of approximately 5 μSv per exposure and a chest x-ray gives a dose of 20 μSv per exposure. However, some procedures, such as CT scans, give higher doses to individual patients who are subject to these. Together with those from dental X-rays etc., this gives an average dose over the UK population due to medical procedures of 410 μSv y^{-1} per person (15% of the average annual total dose from all sources, see Figure 5).

The average annual dose due to radioactive discharges from nuclear facilities in the UK is low in comparison to that from the other man-made sources, that is only about 0.9 μSv y^{-1} compared to 410 μSv y^{-1} for medical exposures, 6 μSv y^{-1} for occupational exposures and 6 μSv y^{-1} as a result of fall-out from past nuclear weapons tests. Only the dose from consumer products such as smoke alarms and photographic lenses results in a lower man-made contribution of about 0.1 μSv y^{-1}. This dose contribution from radioactive discharges from nuclear facilities includes contributions from across the nuclear industry including uranium enrichment, nuclear power stations, fuel reprocessing, defence establishments, nuclear technology services, radionuclide production, research laboratories and disposals to the UK's Low Level Waste Repository in Cumbria. Other industrial sources of radioactive discharges in the UK are NORM industries and small users (such as schools or hospitals) and also originate from disposals of certain types of waste to landfill sites.

4.2 Existing Hinkley Point Monitoring Data

A significant contribution to the historic and potential future baseline for the discharges of artificial radionuclides around Hinkley Point, is due to the historical, current and potential future discharges from the HPA and HPB reactors that are already present on the Hinkley site.

HPA is a Magnox reactor power station with two reactors that has ceased operation and is now in decommissioning. HPB is an AGR reactor power station with two reactors in operation with a current planned closure date of 2016. Both sites have a set of authorisations for liquid and gaseous radioactive discharges into the surrounding environment (liquids to the Bristol Channel, gases to atmosphere). The authorisations have been issued after assessment of the impacts and effects and consultation. The predicted doses from HPA and HPB at the receptor locations that will be those most affected by potential future HPC discharges are presented in Section 7.

The Environment Agencies of the United Kingdom and Northern Ireland and the Foods Standards Agency have, since 1995, produced an annual Radioactivity in Food and The Environment (RIFE)[55, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78] reports that record the results of radiological monitoring of food and environmental sampling programmes in the UK, especially near licensed nuclear sites.

The RIFE reports present a retrospective dose assessment based on the measured activity concentrations in various foodstuffs farmed or caught local to Hinkley Point and on local occupancy and habit data. Table 4 summarises the reported individual annual radiation exposure to the highest exposed critical group used in the RIFE assessment for the Hinkley Point area. The increase in radiation exposure between the year 2005 and 2006 is mainly due to an increase in habits observed in the recent habits survey.

Table 4: Individual radiation exposure reported in RIFE reports for Hinkley Point

Year	Seafood consumers (mSv y^{-1})
2007[55]	0.029
2006[67]	0.040
2005[68]	0.018
2004[69]	0.017
2003[70]	0.013
2002[71]	0.015
2001[72]	0.014

4.2.1 Monitoring Data Presented in RIFE

The most recent RIFE reports (RIFE 8 to RIFE 13 inclusive) have been reviewed and data extracted and summarised for locations close to the Hinkley Point Site. The RIFE reports include an extensive list of nuclides, but only a few of which are actually reported as above detection or as less than a specified detection limit (< values). These are presented in Tables 5, 6 and 7 for drinking water, fresh water and seawater, respectively. Blanks indicate no reported data.

These data show that the radioactive content in drinking water in the reservoir closest to the Hinkley Point Site is low, with the only nuclide consistently positively detected being naturally occurring K-40. Similarly, the results for seawater show a consistent positive result for gross beta, with an average value of around 12 Bq l^{-1}. The gross beta results for seawater reflect the much higher levels of potassium (and therefore of naturally occurring K-40) than are typically present in freshwater (400 mg/l compared with around 10 or 20 mg/l in freshwater).

Other environmental media are also locally sampled and assayed for their radioactive content. These samples include mud sampled 1.6 km from the discharge pipeline, mud from Watchet and sediment from Stolford. These data are summarised in Tables 8, 9 and 10 respectively.

The measured data for mud and sediment (Tables 8 to 10) show consistent positive results for Cs-134 and Cs-137. Information from the RIFE Reports suggest concentrations of these and of other man-made radionuclides in the aquatic environment of the Severn Estuary and Bristol Channel represent the combined effect of historic releases from HPA and HPB, plus other establishments, notably GE Healthcare at Cardiff (mostly tritium) and Berkeley and Oldbury power stations, with smaller, mostly historic, contributions from Sellafield and fall-out from historical weapons testing and from Chernobyl.

Measurements of the external gamma radiation dose rate are also reported in the RIFE reports. These results are summarised in Table 11 below:

Table 11 Averaged gamma dose rate at locations at and around Hinkley Point

Location	Units	RIFE 13[55]	RIFE 12[67]	RIFE 11[68]	RIFE 10[69]	RIFE 9[70]	RIFE 8[71]	RIFE 7[72]	RIFE 6[73]	RIFE 5[74]
		4.7b	4.7b	5.7b	5.7b	5.8b	6.6a	6.6b	6.6b	6.6b

The RIFE reports state these gamma dose rates were barely above the limits of detection (for the survey equipment used)[55]. Most of the gamma flux is probably due to naturally occurring K-40.

All of the RIFE reports include extensive assessments of doses to critical groups due to radioactivity in these solid and liquid environmental media, currently due to discharges from HPA and HPB, discharges from more distant sources (e.g. Oldbury, GE Healthcare at Cardiff) fallout and natural background. These doses are assessed in RIFE using an empirical method involving habits and food consumption patterns coupled with dose per unit intake factors as well as direct measurements. All of these assessed doses are small and all are quoted as being equivalent to only a few percent of the public dose limit of 1,000 µSv y^{-1}.

4.3 Environmental Setting for HPC (site specific investigations)

A summary of findings of recent surveys undertaken on behalf of EDF is provided in the following sections, although some are on-going and results may be revised in the future. Selected graphical data for the results are shown in Appendix A and discussed below.

4.3.1 Marine Monitoring Campaign and Results

A marine monitoring campaign has been carried out to identify background levels of radioactivity in the Bristol Channel in the vicinity of the HPC site. The first campaign of marine surface water quality sampling took place on the 27th and 28th January 2009. The second campaign of marine surface water quality monitoring took place on the 1st and 2nd May 2009. The third monitoring campaign took place on 27th to 28th June 2009, and the fourth campaign on 12th to 13th September 2009. Samples of seawater were scheduled for the following radiochemical analysis suite:

- High Resolution Gamma Spectrometry (HRGS);
- Gross alpha (calibrated with Am-241) and gross beta, (calibrated with K-40);
- Tritium (as tritiated water); and
- Carbon-14.

The majority of the radiochemical analysis results were reported as below detection limits or, if a positive concentration was found, at very low levels marginally above the detection limit. All values measured for anthropogenic radionuclides are very low, consistent with those reported elsewhere and would not present a hazard to human and non-human health or be of regulatory concern.

4.3.2 Groundwater Monitoring Campaign and Results

Groundwater monitoring has been carried out on the Built Development Area West, Built Development Area East and Southern Construction Phase Area. Boreholes were drilled and developed, and samples were collected and analysed for the following radiochemical analysis suite:

- High resolution gamma spectrometry (HRGS);
- Gross alpha (calibrated with Am-241) and gross beta (calibrated with K-40);
- Tritium (as tritiated water); and
- Carbon-14.

The suite was selected to provide a general screen for alpha, beta and gamma-emitters and to provide information with regard to soft beta-emitters (tritium and carbon-14). The inclusion of gross alpha, gross beta and tritium also meets the requirements for drinking water monitoring. The inclusion of gamma spectrometry provides quantitative data with regard to a range of natural and anthropogenic radionuclides.

Five groundwater sampling campaigns were carried out from boreholes drilled in the Built Development Area West, covering the period December 2008 to June 2009. Four sampling campaigns were carried out from boreholes drilled in the Built Development Area East and Southern Construction Phase Area covering the period June 2010 to December 2010.

The gross alpha, gross beta and tritium results for the Built Development Area West are presented graphically in Figures A1 to A3. The gross alpha, gross beta and tritium results for the Built Development Area East are presented graphically in Figures A4 to A6. The gross alpha, gross beta and tritium results for the Southern Construction Phase area are presented graphically in Figures A7 to A9.

The results of the groundwater monitoring showed that no artificial radionuclides measureable by gamma spectrometry were detected. There were a number of examples of sampling locations where, on average, gross beta results were apparently above standards for drinking water. However, these elevated gross beta values were due to the presence of the naturally occurring radionuclide, potassium-40, which is excluded from consideration in standards for drinking water.

Tritium was detected in the water from three boreholes in the north-east of the Built Development Area East close to the Hinkley Point A site boundary. The levels of tritium found were above those typically found in the Hinkley area but below the standards for drinking water (Section 3.4.1.1[45,46,47])[k].

4.3.3 Surface Water Monitoring Campaign and Results

A monitoring campaign was commissioned to investigate background levels of radioactivity in the surface freshwater features (field ditches and a stream) within the site that will be occupied by the planned HPC development and construction areas. Samples were collected from ten monitoring sites during six separate monitoring campaigns covering the period January 2009 to July 2009. The samples were scheduled for the following radiochemical analysis suite:

- HRGS;
- Gross alpha (calibrated with Am-241) and gross beta (calibrated with K-40);
- Tritium (as tritiated water); and
- Carbon-14.

The results of the surface water monitoring campaigns are presented in Figures A10 to A12. The results have shown no significant radiochemical contamination of surface waters and the measured values across all campaigns are below regulatory concern from the standpoint of drinking water standards[k].

4.4 Soil Monitoring Campaign and Results

A survey was carried out to investigate the radiological contamination status of the Built Development Area West. The first stage took place during July 2008 and comprised a ground surface radiological survey of direct gamma radiation using hand-held monitoring equipment. In addition, near surface soil samples (including those from within any “made-ground” that is, material subject to previous disturbance) were collected from across the site (<0.3 m below ground level) and radiochemical analysis was carried out, covering: gross alpha; gross beta; HRGS; and tritium.

[k] Under current radioactive substances regulation there is no *de-minimus* for man-made radionuclides such as tritium in aqueous solutions. However, this legislation is due to change in the near future (expected October 2011). It will then be likely that levels of tritium found in water pumped from these areas, and needing to be considered as waste, will become exempt from radioactive substances regulation. In the mean time, comparison of the levels of tritium found against drinking water standards is considered to be a sufficiently robust assessment of risk.

The second stage of the soil monitoring campaign was undertaken during October 2008 and investigated levels of contamination of deeper soils, between 0.55 m and 5.0 m below the surface. The soil samples were analysed for gross alpha, gross beta, HRGS, C-14 and tritium.

From the data presented in the Baseline Radiological Survey it can be concluded that the levels of radioactivity in the near surface soils in Built Development Area West are similar to background levels found throughout the UK and do not present any radiological hazard above natural background. The levels of Cs-137 are consistent with fallout from atmospheric weapons testing carried out in the 1950's to 1970's and the Chernobyl accident in 1986. No radiological activity values in excess of statutory guidance levels were found. The Phase 1 study concluded that the near surface site soils do not pose an unacceptable risk to human health via direct contact, ingestion or inhalation based on a commercial/industrial end use development.

A survey, including a radiological walkover survey and environmental gamma dose rate measurements, was carried out in October 2009 to investigate the radiological contamination status of the Built Development Area East and Southern Construction Phase Area. The results of the walkover survey and gamma dose rate measurements were generally consistent with background levels. The radiological survey did, however, identify an area of elevated radiation readings close to the eastern boundary of the Built Development Area East land adjacent to the existing Hinkley Point Power Station Complex. This was attributed to radiation gamma shine from a rectangular building situated just inside the Hinkley Point A site boundary and which, at the time of the survey, was being used to store active waste in ISO freight containers.

Following the survey, soil samples were collected from the Built Development Area East and Southern Construction Phase Area and these were analysed for: gross alpha; gross beta; HRGS; C-14 and total tritium. Overall, the radiochemical analysis results for the soil samples collected from the Built Development Area East and Southern Construction Phase Area land provided no evidence of significant contamination with anthropogenic radionuclides and the levels of radionuclides present were generally consistent with background levels. A small area of the Built Development Area East, which was the site of a former sewage works, was found to contain elevated levels of natural uranium, which was associated with granitic material observed in this area. The levels found were below the limit specified in The Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (Statutory Instrument, 1962, No.2648)[79] and would not be of regulatory concern.

In summary, no soil samples (including those from within previously disturbed ground) were found to be "radioactive" as defined by the relevant legislation[18,19,79] nor, in the majority of cases, in excess of normal background levels found in soils in the UK. The site in question is, therefore, not subject to regulatory controls for radioactive substance regulation. Implications for this are discussed in Section 5.1.1.1.

5.0 ASSESSMENT OF IMPACTS

5.1 Key Development Characteristics

5.1.1 Sources of Radiation Exposure to the Public During Construction

5.1.1.1 Potential Radioactive Contamination in Land and Water

Potential sources of exposure of members of the public during the construction phase of HPC include the dispersion of potentially contaminated soils during excavation. If contaminated soil is present on the site the potential exists for the generation of dust during the excavations that will occur during site preparation works. This contaminated dust could then be carried off-site by the wind resulting in the exposure of members of the public who are living or working near the site.

Data for the soils surveys and walkover surveys carried out on the Southern Construction Phase Area, Built Development Area East and the Built Development Area West are described in Section 4.4. The results for the Southern Construction Phase Area and the Built Development Area West showed levels of radionuclides below relevant regulatory criteria, reflecting the past agricultural history of these areas of the HPC site. Desk studies had shown the Built Development Area East as having some potential contaminative uses. However, the soil studies have shown again, no contamination by radionuclides above relevant regulatory levels[18,19,79].

The results found have therefore not warranted a formal radiological public dose assessment. The field and analysis data and the fact that levels of nuclides are below relevant regulatory criteria, make it highly unlikely that construction works on these areas would present a radiological hazard to members of the public adjacent to the works (e.g. from wind-blown soil dust or from soil materials taken off site) over and above that due to any large construction project carried out in the Hinkley Point area.

With respect to ground and surface waters, the measured values for the Southern Construction Phase Area, Built Development Area East and Built Development Area West are below drinking water standards[45,46,47] and therefore would not present a radiological hazard any members of the public in the unlikely event of their coming into contact with ground or surface waters from the site.

5.1.2 Sources of Radiation Exposure During Operation of HPC

An operating nuclear power station will make very small discharges of radioactive material to the environment. These releases are subject to permitting by the regulatory body[19]. In the case of Hinkley Point, this is the Environment Agency of England and Wales. The permit issued will impose various conditions on the discharge including limits, including the volume and activity of the discharge on an annual and possibly quarterly basis, requirements for reporting and commitments by the operator to use best available techniques (BAT) to minimise the discharges. The operator must also report any instances of limits being exceeded with an assessment of the consequences of such events and procedures put in place to prevent their reoccurrence.

Discharges of radioactive materials will occur by the release of radioactive liquids to the marine environment (liquid discharges) and by the release of gaseous radioactive material to the atmosphere. Any particulate material is mostly removed by filters etc, and the amounts of particulates released in gaseous streams are therefore extremely small. Estimates of the liquid and gaseous discharges resulting from normal operations at HPC (EPR East plus EPR West) have been made and are discussed below.

5.1.2.1 Liquid Discharges from HPC

The liquid discharges are carried out in the form of batches from holding tanks but take place at the outlet of the main turbine cooling water culverts, so are subject to immediate dilution with a flow of seawater of the order of 130 $m^3 s^{-1}$ before entering the final outfall system, where thorough mixing takes place prior to the discharged material finally entering the Bristol Channel.

The activity values in liquid discharges and used in the dose assessment are derived from operational feedback from current PWRs (of similar design to the UK EPR) and shown in Table 12. These are appropriate for carrying out a site-specific radiological assessment for the HPC development.

Table 12: Activities for liquid discharges from HPC appropriate to assess radiological impacts[50]

Radionuclide	Annual liquid discharges GBq y^{-1}
H-3	150,000
C-14	190
Cs137	1.89
Ag-110m	1.14
Mn-54	0.54
Sb-124	0.98
Sb-125	1.63
Te-123m	0.52
Cr-51	0.12
Co-58	4.14
Co-60	6.0
Cs-134	1.12
Ni-63	1.92
I-131	0.1

The table shows these HPC liquid discharges consist of the following nuclides (this is a simplified outline of the sources; further details are given in the Chapter 8 of the PCER[24]):

- Tritium: Some tritium is formed within the fuel but contained by the fuel cladding (and therefore removed during refuelling). The rest of the tritium is formed by the neutron capture reaction by Boron (B-10) added for reactivity control and also from Lithium (Li-6). The later is present as an impurity in the Li-7 hydroxide that is added to the coolant to control pH. Tritium can also form in certain operational components in the reactor core (control rods etc.). Most tritium from these sources occurs as tritiated water (^3H_2O) in the coolant. As this flows into other plant systems (particularly during refuelling shutdowns) tritium eventually moves into the liquid radioactive effluent treatment systems and some is eventually discharged.

- C-14: This is formed mainly by activation of oxygen (present as H_2O) and nitrogen (present as a dissolved impurity) in the reactor coolant. As coolant needs to be directed to downstream systems, C-14 passes into these and eventually into liquid discharges that need to be made for operational reasons.

- Activation products of certain metals such as Co-58 and Co-60: These are formed by irradiation of structural materials in the reactor circuit, such as steel (that contains manganese, chromium etc). As water flows around the circuit, some of these 'activation products' can be released and travel around the circuit and pass into other plant systems. Only very minor amounts pass through the radioactive waste treatment systems and eventually into liquid discharges.

- Fission products such as caesium and iodine isotopes: These are formed by fission of fuel in the fuel pins. Some can escape and move through the circuit with the activation products as above. Some are volatile and partition into the radioactive gaseous discharge streams (see below).

The minimisation of these radioactive constituents (and chemical ones as well) in liquid discharges from the UK EPR centres on the following design and management features. Further details are provided in the PCER[50] but since C-14 and tritium dominate doses from HPC to the candidate critical groups, specific details for these two isotopes are given in Section 6, which addresses the mitigation of impacts.

- Minimisation at source. This includes ensuring the leak-tightness of the fuel pins to minimise release of fission products such as iodine into the reactor coolant and controlling the pH of the coolant to minimise corrosion effects that could give rise to Co-60 etc;
- Recycling and reuse of liquids, where possible, in the reactor systems; and.
- Clean-up and abatement of discharges using combinations of filters, ion exchange resins and evaporators that remove activity from the effluents to convert them into more compact and easily managed solid waste forms.

Once the aqueous liquids have been treated they will be directed to a series of hold-up tanks for monitoring and discharge. The tanks have monitoring and sampling systems and also final filter/strainers. Discharges will take place only after suitable monitoring and management checks, and in accordance with conditions that will be laid down in the relevant permit issued under the requirements of the RSR.

5.1.2.2 Gaseous Discharges from HPC

All gaseous discharges from each EPR will be directed to a gaseous discharge stack serving each reactor for monitoring, recording and discharged to the atmosphere. Policy is to direct all discharges to the stacks and minimise fugitive emissions from other sources; any other minor routes are discussed below. The height of the stack on each EPR has been optimised for the Hinkley Point Site to ensure dispersal under all prevailing local weather conditions with minimal grounding of any plume.

The activity values in gases and used in the dose assessment are derived from operational feedback from current PWRs (of similar design to the UK EPR) and shown in Table 13. These are appropriate for carrying out a site-specific radiological assessment for the HPC development. The table shows the discharges consist of the following:

- Rare gas isotopes with mostly short half-lives viz Xe-133 ($t_{1/2}$ = 5.27 days) Xe-135 ($t_{1/2}$ = 9.2 hours), Ar-41 ($t_{1/2}$ = 1.86 hours), Xe-131m ($t_{1/2}$ = 11.96 days): These are formed as fission products in the fuel but small amounts can escape from the fuel and pass into the reactor coolant. As this passes into downstream systems (especially at refuelling) out-gassing occurs and the gases pass into the radioactive gaseous treatment or plant ventilation systems;

- Tritium and C-14: Formation of these takes place mainly in the liquid coolant as described above. Some tritiated water evaporates in downstream plant systems and passes into the gaseous treatment systems and ventilation systems. C-14 is present mainly as CO_2 and methane that out-gas from the coolant in the downstream systems of the plant; and

- Volatile fission products: Predominantly iodine isotopes and some caesium isotopes.

Table 13: Activities for gaseous discharges from HPC appropriate to assess radiological impacts [50]

Radionuclide	Annual gaseous discharges GBq y^{-1}
H-3	6,000
C-14	1,400
Kr-85	6,260
Xe-133	28,400
Xe-135	8,920
Ar-41	1,306
Xe-131m	135
I-133	0.436
I-131	0.364
Co-58	0.0612
Co-60	0.0722
Cs-134	0.0562
Cs-137	0.0504

The minimisation of these radioactive constituents in gaseous discharges from each EPR unit will centre on the following design and management features. Further details are provided in the PCER[50] but since C-14 and tritium dominate estimated doses from HPC to the candidate critical groups, more specific details for these two isotopes are given in this current technical note in Section 6, which addresses mitigation.

- Minimisation at source: The minimisation of gaseous activity at source relies on the same basic principles as for the liquids, especially maintaining the leak-tightness of the fuel pins, since this is the main source of gaseous and volatile fission products in gaseous discharges from any PWR;
- Recycling gases where possible; and
- Treatment and abatement: The main feature of the EPR for treatment and abatement of gaseous discharges is a system that uses catalytic recombination of tritium gas with oxygen. This ensures that tritium and iodine isotopes are retained mainly in an aqueous phase which is returned to the non-recyclable liquid effluent system for final clean-up and discharge in liquid form. There is also a waste gas recirculation line with three activated charcoal beds/hold up tanks. This provides for hold-up and delay for short-lived isotopes of krypton and xenon, sufficient to ensure that only very low levels of these are finally discharged to atmosphere via the central stack.

In the EPR, the design and operation of the heating, ventilation and air conditioning (HVAC) systems that extract air from potentially active areas throughout the plant follows a common approach based on currently accepted international methods used in all nuclear facilities:

- Pre-filters remove the bulk of the active and inactive airborne particulates;
- High efficiency particulate arrestor (HEPA) filters provide the bulk of the particulate decontamination of the extract air. Pre-filters and HEPA filters are disposable and designed to allow minimisation in the volumes of solid radioactive waste they produce. HEPA filters have remote change systems to ensure worker doses are ALARP (worker dose control being under the remit of the NII); and;
- For certain plant areas there are iodine charcoal filter to remove inorganic (and some organic) iodine species.

There is a minor gaseous discharge outlet from the proposed Interim Storage Facility for Spent fuel serving both UK EPR reactors on the HPC site. Gaseous discharges from this are small (an estimate shows it is less than 5% of the values used in the assessment). The gaseous discharge value for HPC (in Table 13) used in the radiological impact assessment implicitly includes a contribution from this facility and therefore no extra headroom in discharges is needed to take account of it.

In keeping with the practical situation on other nuclear sites and consistent with other permits and authorisations, there may be other very minor outlet routes for gases. These include louvers, small vents, windows and doors associated with Controlled areas or laboratories, the turbine hall and small storage areas not specifically listed above.

5.1.2.3 Direct Radiation

In addition to the discharge of radioactive material to the environment, radiation will also be emitted by sealed radioactive sources present on the HPC site. These radioactive sources include the reactor core, spent fuel and contained intermediate and low level radioactive waste. This direct radiation principally comprises gamma photons emitted from these sources in waste stores on-site. The design will ensure that gamma photons will be heavily shielded by the reactor pressure vessel, the walls of the reactor building and the design of the waste stores. The direct radiation doses from HPC are assessed in Section 5.2.2.5.

5.2 Operational Phase Impacts

5.2.1 Stack Height

The ADMS dispersion model was used to predict dispersion and deposition factors for routine releases from a stack height for each EPR at Hinkley point of 70 m (Section 3.4.1.2). The ADMS model used took account of forecasted hourly meteorological conditions from 1st January 2004 to 31st December 2008, generated using the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction model for the Hinkley Point Site. Figure 2 presents the wind rose based on the meteorological data for 2004 to 2008 that formed the basis for the calculations. The wind rose shows that wind is blowing predominantly from the 290^{o} quadrant and therefore from the northwest to the southeast.

Figure 3 presents a graphical representation of the resultant estimated 5 year average of Total Integrated Activity Concentration (Bq m^{-3}) for a release of all radionuclides (Tables 12 and 13) from HPC West (C2) and from HPC East (C1) for a stack height of 70 m.

This stack height is used in the next stage of modelling in PC CREAM98. In this, the required input parameter is called the “effective stack height”. This is routinely calculated by assuming the effective stack height is 1/3rd of the true or actual stack height. This gives a conservative assumption for the stack height from which gaseous emissions take place and the associated dispersion factors.

5.2.2 Assessment of Radiological Impact on Humans

5.2.2.1 Individual Doses Resulting from Continuous Discharges

The radiological impact was assessed by the calculation of prospective doses incurred by various critical groups using PC CREAM98. A summary of the input parameters for this assessment are shown in Appendix B. The PC CREAM programme uses the most recent metrological data from 1999 to 2008.

The assessment considered separate candidate critical groups exposed to discharges to the terrestrial and marine environments. The highest predicted exposures were found for the following two candidate critical groups; a fishing family living and working in the vicinity of the site thereby exposed to both liquid discharges to the marine environment and gaseous discharges to atmosphere (the 'Fishing Family with marine and gaseous exposure') and a farming living in a nearby dwelling who also consume locally sourced seafoods and spend recreational time on a local beach, again exposed to both marine and gaseous discharges (the 'Farming Family with marine and gaseous exposure'). These have already been identified in Section 3.4.1.2.

5.2.2.2 'Farming Family with marine and gaseous exposure'

This family represents the candidate critical group who may be exposed to gaseous discharges from the proposed HPC EPRs and via liquids discharged to marine pathways. It is firstly assumed that this family lives at the location where the highest predicted air and ground activity concentration occurs due to HPC discharges. The radiation exposure to three age groups via this first route was determined; an Infant representing the age range 1-2 years; a Child representing the age group 7 to12 years of age and an Adult representing individuals greater than 17 years of age.

For the purposes of this assessment, it is assumed that the 'Farming Family' consumption rates (based on the most recent CEFAS[53] consumption data for the Hinkley Point Site) for terrestrial foods are calculated based on the 'Top Two' approach. In the 'Top Two' approach, the two foodstuffs, that result in the highest ingestion dose (when all foodstuffs are modelled as consumed at critical rates), are assumed to be consumed at critical rates and all other foodstuffs at average rates. In this instance, the 'Top Two' foodstuffs were found to be: milk and root vegetables for adults, and milk and milk products for child and infant age groups. These foods are assumed to be consumed at the critical rate corresponding to the 97.5th percentile rate and the remaining foodstuffs consumed at mean rates. Where appropriate ratios were not present in the CEFAS report, ratios of adult to child and adult to infant ingestion rates were calculated from generalised habit data[54].

This family is also assumed to consume locally sourced sea-food at mean CEFAS[53] ingestion rates. It is assumed that members of this family can also be exposed to marine discharges through external exposure to beach sediments and the inhalation of sea-spray, whilst spending time recreationally on the beach at Stolford. It is assumed that these individuals do not participate in fishing and therefore are not exposed through the handling of fishing gear exposure pathway.

Occupancy rates for members of this family are given in Appendix B (Table B2) and are based on CEFAS data.

The predicted doses to this 'Farming Family with marine and gaseous exposure' were calculated to be 2.7, 2.5 and 4.5 µSv y^{-1} for the adult, child and infant respectively (the latter is the highest dose estimated for HPC discharges). A dose breakdown by exposure pathway for HPC discharges is presented in Table 14 for the three age groups.

Table 14: Breakdown of predicted doses to the 'Farming Family with marine and gaseous exposure', by exposure pathway, for HPC discharges (µSv y^{-1})

Pathway		Adult	Child	Infant
Terrestrial pathways	Ingestion terrestrial foodstuffs	$2.2\ 10^{0}$	$2.1\ 10^{0}$	$4.3\ 10^{0}$
	Inhalation plume	$1.3\ 10^{-1}$	$1.0\ 10^{-1}$	$7.2\ 10^{-2}$
	Cloud gamma	$3.2\ 10^{-2}$	$1.9\ 10^{-2}$	$1.5\ 10^{-2}$
	Deposited gamma	$1.9\ 10^{-2}$	$9.4\ 10^{-3}$	$6.4\ 10^{-3}$
	Cloud beta	$1.7\ 10^{-3}$	$1.7\ 10^{-3}$	$1.7\ 10^{-3}$
	Deposited beta	$1.1\ 10^{-3}$	$4.4\ 10^{-4}$	$2.2\ 10^{-4}$
	Inhalation re-suspended	$2.6\ 10^{-6}$	$3.3\ 10^{-6}$	$3.7\ 10^{-6}$
Marine pathways	Ingestion marine foodstuffs	$3.0\ 10^{-1}$	$2.9\ 10^{-1}$	$1.2\ 10^{-1}$
	Gamma (sediment)	$3.0\ 10^{-4}$	$1.4\ 10^{-4}$	$7.8\ 10^{-6}$
	Beta (sediment)	$9.4\ 10^{-8}$	$4.2\ 10^{-8}$	$2.4\ 10^{-9}$
	Inhalation sea-spray	$9.6\ 10^{-11}$	$5.2\ 10^{-11}$	$3.4\ 10^{-12}$
Sum for marine and terrestrial pathways for HPC		$2.7\ 10^{0}$	$2.5\ 10^{0}$	$4.5\ 10^{0}$

Overall, in this group, between about 89% (for the child and adult) and 98% (for the infant) of the prospective dose is due to exposure via terrestrial pathways and between about 2% (for the infant) and 11% (for the adult and child) is due to exposure via marine pathways.

5.2.2.3 'Fishing Family with marine and gaseous exposure'

This family represents the candidate critical group who may be exposed to radiation and radioactivity from discharges into the marine environment and via terrestrial pathways. The radiation exposure to the same three age groups as the 'Farming Family with marine and gaseous exposure' (above) was determined. As for that candidate critical group, exposure to gaseous discharges is calculated based on 100% occupancy at a dwelling coinciding with maximum airborne and deposited activity due to these discharges from HPC[l].

[l] This is a realistically conservative assumption because the family would be exposed to lower levels of radionuclides in the plume whilst fishing and spending recreational time on the beach at Stolford.

The family members consume seafood at the 97.5th percentile rates as calculated on all observations in the most recent CEFAS[53] survey of Hinkley Point habits and also consume terrestrial foodstuffs at average (mean CEFAS[53]) rates. For the child and infant consumption parameters, the same methods were used to determine consumption rates. However, in cases where there are no instances of a food group being consumed, child and infant data was derived from adult data using the method described in the CEFAS[53] report. Where appropriate ratios were not present in the CEFAS report, ratios of adult to child and adult to infant ingestion rates were calculated from generalised habit data[54]. Rates are given in Appendix B (Table B1)

There are some foodstuffs (marine plants and algae) consumed by members of the public in the CEFAS survey[53] which have not been included in the current assessment. This is because they are only consumed in small quantities by very few individuals and it is not possible to model these foodstuffs in PC CREAM 98.

The predicted doses to this 'Fishing Family with marine and gaseous exposure' were calculated to be 3.0, 2.3 and 3.6 $\mu Sv\ y^{-1}$ for the adult, child and infant members respectively. A dose breakdown by exposure pathway for HPC is presented in Table 15 below for the three age groups.

Table 15: Breakdown of predicted doses to the 'Fishing Family with marine and gaseous exposure', by exposure pathway, for HPC discharges $\mu Sv\ y^{-1}$

Pathway		Adult	Child	Infant
Marine pathways	Ingestion Marine Foodstuffs	$1.1\ 10^{0}$	$3.1\ 10^{-1}$	$1.2\ 10^{-1}$
	Gamma (sediment)	$1.5\ 10^{-3}$	$1.4\ 10^{-4}$	$7.8\ 10^{-6}$
	Gamma (fishing gear)	$1.2\ 10^{-5}$	-	-
	Beta (fishing gear)	$8.0\ 10^{-6}$	-	-
	Beta (sediment)	$4.6\ 10^{-7}$	$4.2\ 10^{-8}$	$2.4\ 10^{-9}$
	Inhalation Sea-spray	$8.6\ 10^{-10}$	$9.2\ 10^{-11}$	$5.4\ 10^{-12}$
Terrestrial pathways	Ingestion terrestrial Foodstuffs	$1.7\ 10^{0}$	$1.8\ 10^{0}$	$3.4\ 10^{0}$
	Inhalation plume	$1.1\ 10^{-1}$	$1.0\ 10^{-1}$	$7.2\ 10^{-2}$
	Cloud gamma	$3.2\ 10^{-2}$	$1.9\ 10^{-2}$	$1.5\ 10^{-2}$
	Deposited gamma	$1.9\ 10^{-2}$	$9.4\ 10^{-3}$	$6.4\ 10^{-3}$
	Cloud beta	$1.7\ 10^{-3}$	$1.7\ 10^{-3}$	$1.7\ 10^{-3}$
	Deposited beta	$1.1\ 10^{-3}$	$4.4\ 10^{-4}$	$2.2\ 10^{-4}$
	Inhalation re-suspended	$2.1\ 10^{-6}$	$3.3\ 10^{-6}$	$3.7\ 10^{-6}$
	Sum for marine and terrestrial pathways for HPC	$3.0\ 10^{0}$	$2.3\ 10^{0}$	$3.6\ 10^{0}$

Overall, between about 63% (for the adult) and 97% (for the infant) of the prospective dose is due to exposure via terrestrial pathways and between 3% (for the infant) and 37% (for the adult) is due to exposure via marine pathways. Thus, although described as a 'Fishing family', most of the prospective dose assessed to this candidate critical group due to HPC gaseous and liquid discharges is from terrestrial sources.

A separate assessment shows that discharges from the Interim Storage Facility for Spent Fuel have a negligible health impact, being less that 1% of the doses due to gaseous and liquid discharges from the UK EPRs at Hinkley Point.

5.2.2.4 Dose breakdown by Nuclides in the Candidate Critical Groups

The percentage contribution to these predicted doses (in Tables 14 and 15 above) from the individual nuclides in the discharges from HPC are summarised below (Table 16). The table only includes a breakdown where the contributions are greater than 1%.

Table 16: Dose breakdown as a percentage of summated predicted dose by radionuclide for HPC discharges

Nuclide	'Fishing Family with marine and gaseous exposure'			'Farming Family with marine and gaseous exposure'		
	Infant	Child	Adult	Infant	Child	Adult
C-14	90%	92%	94%	89%	92%	93%
I-131	7%	3%	1%	7%	3%	1%
H-3	3%	3%	2%	3%	3%	3%
Xe-135; Co-60; Ar-41; I-133; Cs-134; Cs-137; Xe-133; Co-58;Kr-85; Ag-110m; Sb-124;Te-123m;Sb-125;Xe-131m;Ni-63;Mn-54;Cr-51. Any one of these nuclides always contributes to less than 1% of the total dose due to HPC discharges to any individual (infant, child, adult) in either candidate critical group.						

This table shows that these estimated doses from the HPC EPRs are dominated by contributions from discharges of C-14, tritium and (for the infant and child) also by I-131.

5.2.2.5 Direct Exposure from the Waste Stores on the HPC Site

Any buildings on the HPC site are likely to be designed to ensure that dose rates outside (due to radioactive materials stored or used inside) remain below the public dose limit of 1,000 µSv y^{-1}. This, in turn, will ensure that the outside of the buildings can remain undesignated under the Ionising Radiation Regulations (IRRs), that is without controls on the access to these areas by non-radiation workers (for example, cleaners or site contractors). The radiation exposure will be required to be As Low As Reasonably Practicable (ALARP) and therefore, in practice, dose rates in such areas will lower than the public dose limit of 1,000 µSv y^{-1}. Nevertheless, in the absence of current definitive information on design or the inventory of materials stored, this limit (based on a 2,000 hour working year) forms a conservative basis for the maximum dose rate on the outside surface of the Interim Storage Facility for Spent Fuel and the ILW Store that are proposed to be situated on the periphery of the HPC site, but close to publicly accessible areas outside the site boundary. This equates to a dose rate of 0.5 µSv h^{-1}.

For simplicity, this dose rate is assumed to be at a distance of 1 m from the outer wall of these waste stores. The dose rate at a receptor point can then be approximately estimated using a 1/r relationship, which is appropriate for those in close proximity to a line source (like an elongated building). This becomes a $1/r^2$ relationship for a solid angle less than about 10^o, i.e. for those further away (and which for a notional store 150 m long equates to a distance >850 m).

Direct radiation dose to a walker or recreational user

For HPC, an ILW and a Spent Fuel building are planned to be located at a distance of approximately 40 m from the coastal footpath that runs parallel to the northern boundary of the Hinkley Point Site. The dose rate at this location is therefore:

$$D = \frac{0.5\mu Sv\,h^{-1} * 1m}{40m} = 0.0125\mu Sv\,h^{-1}$$

A standard scenario for this type of assessment of direct dose would be a member of the public walking their dog daily along this path of about 800 m long and back again. Walking at a rate of approximately 5 km h^{-1}, they could therefore spend about 10 minutes per day walking past the site in the vicinity of the waste stores. It is conservatively assumed that the dose rate along this 800 m walk remains constant at the peak rate of 0.0125 µSv h^{-1} calculated above. The direct dose received has been calculated to be 0.76 µSv y^{-1}. It might be assumed that they walk back along the same path each day (making a 20 minute walk) and would therefore receive this dose twice i.e. 1.5 µSv y^{-1}. This is a conservative estimate, as the dose rate would only be 0.0125 µSv h^{-1} whilst in the walker was in the immediate vicinity of the waste stores (~150 m long) and would drop-off at a rate of $^1/r^2$ along the rest of the path, resulting in dose rates of approximately a factor of 10 lower at the extreme ends of the path/walk.

Another scenario for this type of assessment would be a member of the public walking their dog but spending 2 hours per day stationary in the immediate vicinity of the waste stores. In this case, the calculated annual direct dose to this most exposed person would be 9.13 µSv y^{-1}. However, the assumption of spending 2 hours per day over a year standing at this location adjacent to the Spent Fuel and ILW waste stores on the HPC site is an overly conservative scenario.

Direct radiation dose to closest local residents

The nearest dwelling to the proposed ISF for spent fuel and ILW is at a distance of about 1.3 km from the where the stores would be located on the HPC site. A local resident spending the whole year in this nearest dwelling would receive the highest direct dose of all local residents due to direct radiation from the stores. The external dose here is equal to the dose rate multiplied by the exposure time but also taking into account the reduced dose rate indoors (due to shielding effects of the walls of the dwelling). Taking account of these factors, the annual dose for the nearest dwelling due to the waste stores is estimated from:

$$Dose = \frac{1}{r^2} D \times \left(LF_i \times O_i + LF_o \times O_o \right)$$

r = distance from the spent fuel/ILW waste store to the receptor point, m
D = dose rate at 1 m from the waste store wall, µSv h^{-1}

$LF_{i,o}$ = indoors and outdoors Location Factors
O_i = Indoors Occupancy h y^{-1} = fraction of time indoors x occupancy
O_o = Outdoors Occupancy h y^{-1} = fraction of time outdoors x occupancy

The estimated dose rate at the nearest dwelling at 1,300 m is just 0.3 pSv h^{-1}.

The dose to an adult spending 4,380 hours per year (50%) indoors and 4,380 hours per year outdoors is calculated as:

$$Dose = \frac{1}{1300^2} \times 0.5 \times (0.1 \times 4380 + 1 \times 4380) = 1.43 nSv\, y^{-1}$$ (0.0014 μSv y^{-1})

The dose to a child spending 7,008 hours per year (80%) indoors and 1,752 hours per year outdoors is calculated as:

$$Dose = \frac{1}{1300^2} \times 0.5 \times (0.1 \times 7008 + 1 \times 1752) = 0.73 nSv\, y^{-1}$$ (0.0007 μSv y^{-1})

The dose to an infant spending 7,884 hours per year (90%) indoors and 876 hours per year outdoors is calculated as:

$$Dose = \frac{1}{1300^2} \times 0.5 \times (0.1 \times 7884 + 1 \times 876) = 0.49 nSv\, y^{-1}$$ (0.0005 μSv y^{-1})

Direct radiation dose to members in the candidate critical groups

The dose rate at the more distant location assumed for the ‘Farming’ or ‘Fishing’ families with marine and gaseous exposure (Section 5.2.2.) due to the waste stores at HPC is estimated as 0.17 pSv h^{-1} (compared with 0.3 pSv h^{-1} at the closest dwelling). For adult occupancy, this is equivalent to an annual exposure of 0.82 nSv y^{-1} (compared to 1.43 nSv y^{-1} for the adult in the closest dwelling). Direct doses to the infant and child in the Farming or Fishing families would also be proportionately smaller than for those in the closest dwelling to the stores.

For individuals in these two candidate critical groups, the predicted doses due to direct radiation from the waste stores on the HPC site are therefore very significantly less than those due to gaseous and liquid discharges (Sections 5.2.2.2 and 5.2.2.3); they need not be considered in assessing the cumulative dose from the HPC EPRs to individuals within either of these two candidate critical groups.

Summary of direct radiation doses due to HPC waste stores and assessment against dose criteria

A summary of the predicted doses from direct radiation from the proposed Interim Storage Facilities for Spent Fuel and ILW on the HPC site periphery is shown in Table 17.

Table 17: Summary of predicted direct radiation doses to the public due to the waste stores

Scenario	Estimated dose μSv y^{-1}
Coastal path – moving receptor (walk)	1.5 μSv y^{-1}
Closest dwelling – worst case (adult spending 4,380 hours per year indoors and 4,380 hours per year outdoors)	0.0014 μSv y^{-1}
'Farming or Fishing Family with marine and gaseous exposure' (candidate critical groups; adult occupancy as above)	0.00082 μSv y^{-1}

It should be noted that the assumptions used in the assessment are conservative (including the public dose limit of 1,000 μSv y^{-1} on the walls of the waste stores) so that the actual public doses associated with any form of waste store on the site periphery are expected to be below those estimated in Table 17.

5.2.2.6 Critical Group for Hinkley Point C and Assessment of Prospective Doses against the Dose Constraint for New Sources

The source dose constraint for the maximum dose to people that may result from discharges from a single new source of 300 μSv y^{-1} applies to the dose from proposed discharges and direct radiation (Section 3.4.1.1). Moreover, the Health Protection Agency (HPA-RPD) specifically advises the UK Government to select a value for the constraint for members of the public for new nuclear power stations and waste disposal facilities that is less than 150 μSv y^{-1}.

Table 18 summarises the prospective doses to members of the two candidate critical groups due to HPC discharges (from Tables 14 and 15). The small dose due to direct radiation from the ISF for Spent Fuel (Section 5.2.2.5) would not add measurably to these assessed doses for any members in either candidate critical group:

Table 18: Summary of prospective doses to candidate critical groups due to HPC discharges

Age group	'Farming Family with marine and gaseous exposures'	'Fishing Family with marine and gaseous exposures'
Adult	2.7 μSv y^{-1}	3.0 μSv y^{-1}
Child	2.5 μSv y^{-1}	2.3 μSv y^{-1}
Infant	4.5 μSv y^{-1}	3.6 μSv y^{-1}

Table 18 shows that the highest prospective doses due to HPC routine continuous discharges (based on the activity values in Tables 12 and 13) plus the small contribution from direct radiation from the waste stores are 4.5 μSv y^{-1} to the infant and 2.5 μSv y^{-1} to the child in the 'Farming Family with marine and gaseous exposures'. The dose to the adult in the 'Fishing Family with marine and gaseous exposures' is marginally higher than to the adult in the Farming family. However, taking account of the differences in doses, the assessment shows that the

'**Farming Family with marine and gaseous exposures'** is the **Critical Group** due to HPC routine continuous discharges (plus direct radiation).

The prospective doses to this critical group are well below the source constraint of 300 μSv y^{-1} and also below the HPA-RPD guidance of 150 μSv y^{-1}. All members of the candidate critical groups ('Farming with marine and gaseous exposure' and 'Fishing Family with marine and gaseous exposure') would therefore be afforded at least the same level of protection.

The prospective doses to all members in both candidate critical groups for discharges from HPC (based on values in Tables 12 and 13) are below 10 μSv y^{-1}. This is the level at which the UK Government in its statutory guidance to the Environment Agency has stated that the agency should not seek further progressive reductions in discharge limits that are in place provided that the holder of the authorisation applies and continues to apply Best Available Techniques (BAT; Section 2.3.2).

The approach and parameters used for the Generic Design Assessment (Section 3.4.1.2) and the HPC annual dose assessments (Section 5.2.2) are different and therefore it is not appropriate to compare the results directly. However, results from the GDA are higher than those for HPC and, as such, the HPC assessment is within the envelope described in the GDA.

5.2.2.7 Collective Dose Due to HPC Discharges and Assessment against the Collective Dose Criteria

Relevant parameters for a prospective collective dose assessment are provided in Appendix C. All the prospective collective doses are based on a single year of discharge and truncated at 500 years.

The prospective collective doses to the UK, European and World populations from HPC gaseous discharges (Table 13) have been calculated to be 0.36, 2.99 and 24.6 Man Sv respectively. The collective doses to the UK, European and World populations from HPC liquid discharges have been calculated to be 0.021, 0.20 and 2.2 Man Sv respectively. Total prospective collective doses due to HPC discharges are therefore 0.4, 3.2 and 26.8 Man Sv for the UK, Europe and World populations respectively. These results are presented in Table 19 below.

The prospective *per caput* doses from gaseous discharges from HPC are equivalent to 6.55, 4.27 and 2.46 nSv for populations of the UK, Europe and World respectively. The *per caput* doses from marine discharges from HPC are equal to 0.38, 0.29 and 0.22 nSv for populations of the UK, Europe and World respectively. Average total prospective *per caput* doses due to HPC discharges are therefore 6.9, 4.6 and 2.7 nSv for the UK, Europe and the World (and included in Table 19, over).

Table 19: Collective dose to the UK, European and World populations from HPC discharges

	Collective Population		
Collective dose (Man Sv y^{-1} discharge)	UK	Europe	World
Gaseous discharges	0.36	2.99	24.6
Liquid discharges	0.021	0.20	2.2
Total collective dose due to HPC liquid and gaseous discharges	0.4	3.2	26.8
Average per caput dose (nSv y^{-1} discharge)	UK	Europe	World
Gaseous discharges	6.55	4.27	2.46
Liquid discharges	0.38	0.29	0.22
Per caput dose nSv due to HPC liquid and gaseous discharges	6.9	4.6	2.7

The collective dose to the UK population (truncated at 500 years) in Table 19 of 0.4 Man Sv y^{-1} due to liquid and gaseous discharges from HPC is less than the guideline of about 1 Man Sv y^{-1} that the IAEA considers sufficiently low that they may allow a practice or source to be exempted from regulatory control[(f)] (Section 3.4.1.1).

The per caput doses to the UK, European and World populations (truncated at 500 years) in Table 19 are all of the order of a few nSv y^{-1}. They are therefore in the range of a few nSv y^{-1} that, in the EA interim guidance document on assessment of prospective public doses, are stated should be ignored in the decision making process, as the associated risks are 'miniscule' and the contribution to total doses to individuals will be insignificant (Section 3.4.1.1)[42].

Table 19 shows that the assessed collective dose due to HPC is due mainly to gaseous discharges. Of the nuclides in these, C-14 accounts for between 95% and 100% of the collective dose to all of the populations considered. However, these doses are all much lower than that from naturally occurring C-14 to the UK population alone (about 480 man Sv y^{-1}; European Commission)[48]. Similarly, the *per caput* dose from HPC gaseous discharges to the UK (6.55 nSv y^{-1}) is much smaller than that due to naturally occurring C-14 (of the order of 8.8 μSv y^{-1}).

C-14 contributes to the bulk of the dose due to the HPC liquid discharges as well, although there is no data on natural sources and doses against which to compare this.

5.2.2.8 Individual Dose Resulting from Short-Term Gaseous Discharges and Assessment against Dose Criteria

ADMS has been used to model the dispersion of the aerial discharges using the Hinkley Point Site meteorological data for the months June to August for the years 1999 to 2008.

The dynamic food chain models described in FARMLAND (Brown and Simmonds, 1995)[80] and RP72 (Simmonds,1995)[81] have been used to determine doses from the ingestion of foodstuffs in the year following the release for all radionuclides except for H-3 and C-14. The fruit model is described in NRPB-W46 (Teale and Brown, 2003)[82]. The compartment modelling software ModelMaker4 (Modelkinetix) has been used to replicate the FARMLAND models. Concentrations of tritium and C-14 in foodstuffs were modelled using the specific activity method. Transfer and intake rates for animals and crops have been taken from RP72[81].

The pathways of exposure and the exposure times which have been considered to assess the short-term impact are the following:

- Ingestion of foodstuffs: the associated dose is calculated in the year following the short-term release;
- Inhalation and external irradiation from the plume: the associated doses are calculated for the period of the passage of the plume; and
- External irradiation from deposited radionuclides: the associated dose is calculated for the year following the release.

The input parameters, total discharge amounts, and discharge rates for the short-term scenario are presented in Appendix D.

Individual doses as a result of a short-term, 24 hour gaseous discharge to atmosphere have been calculated for a separate and specific critical group located at the location at which the highest 95th percentile air concentration and ground deposition rate is predicted to occur and based on the 10 years of summer meteorological data (this corresponds to the periods when cropping and harvesting occurs and thus gives a maximum likely nuclide up-take into local produce). Doses have been calculated as a result of a short-term discharge from the HPC West (C2) stack as this stack represents the worst case discharge for the worst case receptor. It is unlikely that both EPR reactors would discharge at elevated short-term rates simultaneously.

As for the continuous dose assessment, ingestion doses have been reported for the CEFAS[53] food intake rate scenario, using the same “Top Two” calculation. All other exposure routes are identical.

The results for the CEFAS[53] intake rate give summated doses of 0.26, 0.23 and 0.45 µSv per short-term discharge for the adult, child and infant age groups respectively. For infants (the most exposed individual) the most significant exposure route is ingestion (97% of the dose received) followed by inhalation (2%). The most significant radionuclide is C-14 (95% of the dose received) followed by tritium (2%).

The prospective doses to any of the individuals in this specific critical group exposed to short-term gaseous discharges from HPC are all significantly less (by about an order of magnitude) than those to any of the individuals in the candidate critical groups due to continuous routine releases i.e. doses to the ‘Fishing or Farming families with marine and gaseous exposure’ (which are all in the range of 2.3 to 4.5 µSv y^{-1} as summarised in Section 5.2.2.6).

The prospective doses estimated due to the short-term discharges from HPC are significantly less than the relevant dose criteria, that is the source constraint of 300 µSv y^{-1} or the public dose limit of 1,000 µSv y^{-1} (Section 3.4.1.1).

5.2.2.9 Build-Up Due to HPC Discharges

In order to determine the radiological impact of the build-up of radioactivity in the environment resulting from discharges from HPC, it is necessary to predict the concentrations in soil, seawater and sediments after 60 years of continuous discharges. This is the planned operational life time of the power station. Build-up parameters are included in Appendix E.

Table 20 presents the results calculated using PC CREAM, for the airborne concentrations and consequent concentration in soil at the off-site location with the highest concentration at year 60 from HPC (C1 plus C2) discharges. As prevailing winds are north westerly, the highest concentration will occur in a south easterly location from the site. Note that default values for deposition velocity of noble gases, tritium and C14 in PC CREAM are zero, so Table 20 shows no calculated build-up for these isotopes. It should be noted that for tritium and C-14 either the build-up dose coefficient is very low or not published and so build-up concentrations were not assessed.

The results for the activity concentration in the seawater and seabed sediments off the coast of Hinkley Point calculated using the DORIS module of PC CREAM at year 60 from HPC discharges are presented in Table 21.

Table 20: Soil concentration at the off site location with the highest concentration at year 60 from HPC (C1 and C2) discharges.

Nuclide	Air Concentration Bq m^{-3}	Soil Concentration Bq kg^{-1}
H-3	$3.6\ 10^{-01}$	-
C-14	$8.3\ 10^{-02}$	-
Ar-41	$7.7\ 10^{-02}$	-
Co-58	$3.6\ 10^{-06}$	$8.8\ 10^{-05}$
Co-60	$4.3\ 10^{-06}$	$2.3\ 10^{-03}$
Kr-85	$3.7\ 10^{-01}$	-
I-131	$2.1\ 10^{-05}$	$4.8\ 10^{-04}$
I-133	$2.6\ 10^{-05}$	$6.3\ 10^{-05}$
Xe-131m	$8.0\ 10^{-03}$	-
Xe-133	$1.7\ 10^{+00}$	-
Xe-135	$5.3\ 10^{-01}$	-
Cs-134	$3.3\ 10^{-06}$	$7.6\ 10^{-04}$
Cs-137	$3.0\ 10^{-06}$	$5.9\ 10^{-03}$

Table 21: Activity concentration in the seawater and seabed sediments off the coast of Hinkley Point at year 60 from HPC discharges

Nuclide	Activity concentrations in unfiltered seawater (Bq l^{-1})	Activity concentrations in seabed sediment (Bq kg^{-1})
H-3	$1.57\ 10^{+00}$	$1.07\ 10^{+00}$
C-14	$2.00\ 10^{-03}$	$1.19\ 10^{-01}$
Mn-54	$5.34\ 10^{-06}$	$4.03\ 10^{-05}$

Nuclide	Activity concentrations in unfiltered seawater (Bq l^{-1})	Activity concentrations in seabed sediment (Bq kg^{-1})
Ni-63	$2.01\ 10^{-05}$	$3.60\ 10^{-03}$

Prospective dose to a future construction worker off-site due to build-up from HPC discharges and assessment against dose criteria

The radiological impact of the build-up of gaseous discharges has been assessed. Section 3.4.1.6 introduced the methodology for assessing doses from contaminated land off-site and stated that the most restrictive scenario would be future construction on such an off-site area. It has been assumed that the most contaminated land off-site would be used for construction of this future off-site development. It is assumed that a construction worker would spend 2,000 hours per year working on this potentially contaminated site, 10% spent disturbing ground (manual digging, 20 hours per year and mechanical digging, 180 hours per year) and 90% of the time (1,800 hours) involved in other activities on the site.

The prospective dose to this off-site future construction worker as a consequence of the future build-up of nuclides due to the emissions from the HPC EPRs has been calculated to be $4.4\ 10^{-3}$ µSv y^{-1}. Approximately 100% of this is accounted for by the external exposure from the ground. Co-60 accounts for about 58% of this external dose. Cs-137 is also a large contributor to external dose, contributing 32%.

These prospective annual doses due to potentially contaminated ground are much smaller than typical measured terrestrial dose rate around Hinkley Point of about 0.07 µGy h^{-1} (see Table 52 of CEFAS, 2007)[53]. The predicted exposure to a future construction worker resulting from the build-up of discharges from two EPRs is equivalent to only about 4 minutes exposure per year to the local natural terrestrial background radiation.

NRPB-W36[59] recommends in its advice on radiological protection objectives for contaminated land, that it is unlikely that significant expenditure to reduce the risk to a member of the critical group of site occupants below about 10^{-6} y^{-1} would be warranted on radiological protection grounds. This risk corresponds to a dose of about 20 µSv y^{-1}. For HPC, the total maximum prospective dose to a future construction worker is 4.4 10^{-3} µSv y^{-1} which broadly corresponds to a risk value of 10^{-6} y^{-1} and therefore implies no restriction on future use of off-site land most affected by build-up due to HPC gaseous discharges.

The predicted annual exposure to a future-use construction worker estimated above is based on the build-up of activity at the location of maximum predicted concentration outside the HPC site boundary. The extent of this area of maximum concentration is relatively small and will reduce with distance from the site.

Prospective dose for marine users due to build-up from HPC discharges and assessment against dose criteria

Coastal or marine based activities other than those associated with fishing, as listed in the CEFAS[53] report are: dog walking, horse riding, playing, bird watching, fossil hunting, deckchair rental, operating donkey rides, beach combing, kite flying and walking. Commercial fishing would result in higher occupancies and intakes than the above. Therefore, the dose to members of the public from future use of the sea has been assessed as the Fishing Family group in Section 5.2.2.3 but excluding the atmospheric contribution. The prospective doses to the Fishing Family due to build-up from marine discharges from HPC were calculated to be 1.08, 0.30 and 0.120 µSv y^{-1} to adults, children and infants respectively. In this particular case, generic UK habit values[54] would result in slightly higher doses for adults than those presented here based on CEFAS habit data.

The prospective doses due to build-up from HPC for marine users are significantly lower than the public annual dose limit (1,000 µSv y^{-1}) and also significantly below the average exposure from all natural and man-made sources to an individual in the UK of 2,700 µSv y^{-1} (Watson et al, 2005)[65].

5.2.3 Assessment of Radiological Impact on Non-Human Species from Hinkley Point C discharges

To enable the assessment of the radiological impact on non-human species resulting from continuous discharges from HPC, four representative habitats were selected for the species they are likely to support in the vicinity of the proposed power station site.

- Habitat 1 lies adjacent to the Hinkley Point C boundary;
- Habitat 2 comprises the coastal mudflats and marine habitat of the adjacent estuary;
- Habitat 3 lies within the Bridgwater Bay National Nature Reserve and includes both shoreline and a fringing terrestrial area; and
- Habitat 4 comprises a small freshwater pond and lies within Habitat 1.

The location of the four habitats with respect to the Hinkley Point Site is presented in Figure 4. As the majority of marine biota is mobile, assessing the activity concentration at a single receptor point where these species live has little value, particularly given the highly dynamic nature of the tides, currents and sediments of the Severn Estuary and Bristol Channel. By assessing the average activity concentration in a small area of sea around the discharge point, the radiation exposure over a period of time of any biota present is more likely to be determined. The local compartment as defined in PC CREAM for Hinkley Point has been used for this purpose to determine concentrations in seawater and seabed sediments.

Using meteorological data, it is possible to calculate, at specific bearings and distances from the HPC stacks the concentration in soil and air of gaseous discharged radionuclides.

Parameters used for the calculation of the radiological impact on non-human species are presented in Appendix F.

Results for the assessments for HPC are summarised below. The assessments for HPA, HPB and for the cumulative site are presented in Section 7.2.

Habitat 1: Terrestrial

The assumption was made that all the species currently within the study site occupy an area south-east of the EPR stacks, corresponding to an area within the Hinkley Point Nature Trail, as this is in the direction of the prevailing winds. The nature trail is a Nature Reserve and a designated County Wildlife Site. This also corresponds to the off-site area where air concentration and consequent deposition is highest for EPR discharges for a 70 m stack height. This habitat will be the main receptor habitat for impacts due to gaseous discharges from HPC.

The surveys showed that the majority of the ERICA default organisms were present in Habitat 1. However, for completeness, all of the ERICA default organisms were included and modelled, regardless of whether they had been identified in Habitat 1 or not. Additionally, there were bats and badgers present on site, which could not be matched to any existing ERICA organisms. It was necessary, therefore, to create new organisms within ERICA to model these particular mammals. Bats are of specific importance as they are a protected species and therefore of particular value and sensitivity (see Table 2 in Section 3.4.2.1).

For the HPC discharge, the risk quotients for gaseous releases and subsequent impacts on the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms and the additional custom organisms, badger and bat, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient (RQ) estimated was 4.17 10^{-4} for badgers (with all other species, including bats, below this). The associated dose for these organisms is 4.17 10^{-3} µGy h^{-1}.

Doses and RQs for noble gases have also been determined. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 1, the highest dose rate due to noble gases discharged from HPC is received by caterpillars, calculated as 1.56 10^{-3} µGy h^{-1}.

Habitat 1 is not a SSSI. However, it is a habitat for bats and therefore special protection of the bats and their roosts must be considered. All the estimated doses from the HPC discharges are below the most stringent assessment level (10 µGy h^{-1}).

Habitat 2: Marine

The marine environment encompasses Bridgwater Bay and the coastal mudflats. These are modelled within DORIS as the local compartment for Hinkley Point. Default data are available within DORIS for Hinkley Point. A large number of species have been reported to reside here and this would be the region most influenced by any liquid discharge. The surveys showed that the majority of the ERICA default organisms were present in this Habitat but again, for completeness, all of the ERICA default organisms were included and modelled, regardless of whether they had been identified or not.

For the HPC discharge, the RQs for liquid releases to the marine environment on marine organisms were calculated for each of the default ERICA organisms based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 1.28 10^{-4} for mammals and reptiles. The associated dose for these organisms is 1.28 10^{-3} µGy h^{-1}.

Habitat 2, as part of Bridgwater Bay, is a designated site and therefore of interest to regulators. All the estimated doses from the HPC discharges are below the most stringent assessment level (10 µGy h^{-1}).

Habitat 3: Coastal

Habitat 3 encompasses Bridgwater Bay and the coastal mudflats at Stolford and extends eastwards to include salt marsh land. As some non-human species living in this habitat are potentially affected by liquid and gaseous discharges it was necessary to carry out an assessment for both discharges. The marine environment is also within the Hinkley Point local compartment. The terrestrial element of Habitat 3 is represented by an area of land close to the coast. It was assumed that bats and badgers would also be present at this location, and therefore the assessment included all ERICA default organisms together with bats and badgers. This habitat was selected, as Bridgwater Bay National Nature Reserve has been classified as a Ramsar site, a Special Area of Conservation, a Site of Specific Scientific Interest and a Special Protection Area so is of high importance to the Environment Agency and Natural England.

For the HPC discharge, the RQs and dose due to liquid releases to the marine environment to marine organisms were determined for each of the default ERICA organisms based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 1.28 10^{-4} for mammals and reptiles. The associated dose to these organisms is 1.28 10^{-3} µGy h^{-1}.

For the HPC discharge, the RQs for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default

ERICA organisms and the additional custom organisms, badger and bat based on a screening value of 10 µGy h^{-1} The maximum risk quotient was 2.46 10^{-5} for badgers. The associated dose rate to these organisms is calculated as 2.46 10^{-4} µGy h^{-1}.

Doses and RQs for discharges of noble gases from HPC were determined. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 3, caterpillars receive the highest dose rate of 8.90 10^{-5} µGy h^{-1}.

Habitat 3 has some sites and habitats within it that have specific designated status and therefore are of high importance to stakeholders. However, all the estimated doses from the HPC discharges are below the most stringent assessment level (10 µGy h^{-1}) meaning that there would be no measurable effects on these organisms as a result of radioactivity present from radioactive discharges from HPC.

Habitat 4: Freshwater

The freshwater habitat is contained within Habitat 1 and is a small pond located near to the southern boundary of the Hinkley Point Nature Trail. It is a Nature Reserve and a designated County Wildlife Site. The pond has no river or stream input or outputs so is a stationary body of water. The freshwater organisms identified in the Hinkley Point area are assumed to reside in or visit this area and therefore to be potentially exposed to radionuclides in the runoff from the watershed area of the pond. The surveys showed that the majority of the ERICA default organisms were present in this Habitat but again, for completeness, all of the ERICA default organisms were included and modelled, regardless of whether they had been identified or not. The SRS 19 (IAEA, 2001)[83] approach for modelling discharges into the environment was used to calculate freshwater and pond sediment concentrations within the ERICA model.

For HPC, the risk quotients for freshwater organisms were calculated for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 8.33 10^{-2} for insect larvae. The associated dose for these organisms is 8.33 10^{-1} µGy h^{-1}.

Organisms common to both Habitat 1 and Habitat 4 include amphibians, birds, gastropods and mammals. The dose received by these organisms due to the gaseous discharges from HPC via both the terrestrial and marine pathways from HPC are; 3.25 10^{-2} µGy h^{-1}, 2.66 10^{-2} µGy h^{-1}, 4.04 10^{-1} µGy h^{-1} and 3.78 10^{-2} µGy h^{-1} respectively. The doses do not include those from noble gases.

Habitat 4 is not an SSSI or otherwise designated site and all the estimated doses from the HPC discharges are below the most stringent assessment level (10 µGy h^{-1}).

Summary of impacts on non-human species due to HPC discharges

In all four of the representative habitats, the assessed doses due to discharges from HPC to non-human species included in ERICA and those specifically identified and modelled (bats and badgers) are below the ERICA default screening value of 10 µGy h^{-1}. This implies no measureable harm to any of these organisms as a result of radioactivity present from radioactive discharges from HPC at the values used in the assessment (Tables 12 and 13 and Section 3.4.2.1).

A separate ERICA assessment for Habitat 1 was carried out and showed that doses and risk quotients due to discharges from the Interim Storage Facility for Spent Fuel are three orders of magnitude lower than those due to discharges from the two HPC reactors.

5.2.4 Assessment of Radiological Impact of Transport of Radioactive Materials to and from Hinkley Point C

The HPC EPRs will require regular shipments of solid radioactive materials as part of normal operation and non-destructive testing (NDT sources) during construction. These shipments will include the delivery of new fuel and the removal of low level waste (LLW). With respect to spent fuel, the EPR allows for long-term on-site management, pending a final management policy for spent fuel in the UK. Significant ILW transport is unlikely to be required until decommissioning.

This section presents the results of an assessment of the radiological consequences of the transport of radioactive materials to and from the HPC site under normal conditions of transport. Assessment of the radiological impact of the transport of radioactive materials to and from the HPC site has therefore considered the transport of the following radioactive materials:

- Radiography sources (used for non-destructive radiography testing of pipe work etc, i.e. NDT sources);
- New fuel;
- Low level radioactive waste (LLW) that includes mainly operational waste such as used personal protection equipment and filters; and
- Spent fuel[m].

A substantial amount of radiography can be expected to take place on site but the number of transports to and from the site of such sources will be limited as a

[m] Although on-site storage of spent fuel is the default position for the EPR, to cover the possible need for spent fuel transport (the most active materials arising on site) an assessment of doses from this from the HPC site has been included in the current assessment.

source store would be expected to be provided on-site. It is assumed that the radiography source is Ir-192 (in common use for radiography) and that the source will be replaced after about 3 to 5 months. It is assumed that there would be 10 radiography teams on-site during construction, requiring 40 new radiography source transports to the site per year. Such sources, when in their transport package, are likely to have a Transport Index (TI) of 0.2, i.e. a dose rate of 2 $\mu Sv\ h^{-1}$ at 1 m[65].

For the purpose of this part of the assessment, it has been assumed that the two UK EPR reactors will work on an 18 month refuelling cycle. The largest shipment of new fuel will occur prior to first start up of each reactor. The UK EPR core contains 241 fuel assemblies. Therefore the first loading of each reactor will require the shipment of approximately 250 fuel assemblies. Information from NRPB-W66 (Watson, 2005)[84] suggests that PWR new fuel casks have a typical TI of 0.4 per package. Assuming each shipment consists of 1 fuel cask holding 2 fuel assemblies with a TI of 0.4, there would be a total of 125 shipments of new fuel. A TI of 0.4 equates to a dose rate at 1 metre from the vehicle of 4 $\mu Sv\ h^{-1}$.

The PCER Sub-Chapter 6.3, (EDF, 2008)[50] details the outputs for the operating installation. There are a total of 650 LLW packages that need to be transported off-site per year for conditioning and disposal. It is assumed that the drummed wastes can be transported in seven full height ISO freight containers. It is likely that the 1 m^3 metallic boxes would be transported individually to the recipient. This combination would result in a total of 19 LLW movements per year. This information is summarised in Appendix G together with typical dose rates for these consignments as given in NRPB-W66[84].

Typical spent fuel transport practices for existing UK reactors are one to two fuel flasks per week[84]. As UK stations tend to be dual reactor stations, the same number of movements can be assumed for HPC. Therefore, it has been assumed that (should spent fuel be transported off-site) each EPR reactor would give rise to one flask of fuel per week, and that flasks from both reactors would be transported from the rail head by rail together in a single consignment.

5.2.4.1 Occupancy of Sites Past which Transport from Hinkley Point C Occurs

It is assumed that there is a single route from Hinkley Point to Bridgwater, with the supposition that a Cannington bypass is not constructed. In the absence of the Cannington bypass, the route would need to pass through Cannington (a small village with a population of approximately 2,500) and would involve a stop at a junction close to a large college and a bus stop. Dose assessments for road transport considered vehicles stopping at this junction for periods of up to 1 minute per conveyance. This is the time period assumed in NRPB-W66[84]. However, similar exposure scenarios could also occur on alternative routes. For this reason, separate assessments are made for dwellings elsewhere, one at a railhead where flasks are handled and one on a generic road route. The details of the scenarios below, including the types and forms of radioactive material, are summarised in Appendix G, Tables G3.

Bus stop exposure scenario

It is conservatively assumed that a member of the public could be waiting for a bus for 10 minutes at the same time every morning of the working week at the bus stop near the junction in Cannington and is assumed to be present for ¼ of the transports involving the sources used for NDT radiography over a period of one year at an exposure time of 1 minute per transport.

This same member of the public may also stand at a bus stop as a shipment of new fuel is transported past, on its way to the HPC site. However, it is considered unrealistic for this individual to be exposed to more than one new fuel transport per day. As it is predicted that 125 fresh fuel shipments will be required for first loading of the reactor, this is likely to occur over several days (it has been assumed to take a week). The fraction of a working day that the individual is present at the bus stop is 10 minutes every 8 hours (0.021/day). With 125 deliveries, this corresponds to the individual being present for 2.6 transports of new fuel. It is conservatively assumed that a member of the public could be exposed to up to 5 new fuel transports, consisting of one per day over 5 working days.

The member of the public could reasonably conservatively be at the bus stop for a quarter of the assumed 19 movements of LLW from the site to an off-site LLW facility, that is about 5 LLW transports per year.

With respect to an assumed two spent fuel transports per week from the HPC site, it is unlikely both these would pass the individual at the bus stop in a 10 minute timeframe; therefore it will be assumed that this member of the public is present for 1/4 of movements from a single EPR site, thus resulting in exposure to 13 transports of spent fuel from the HPC per year.

Education establishment exposure scenario

As the nearest building to the Cannington junction is an education establishment at a distance of 15 metres from the road, occupancy times would be limited to around 5 hours per day during term time, here assumed to be 40 weeks. It is therefore reasonable to assume that the same person is in the building and therefore potentially exposed to all radioactive material transports occurring for 40 weeks of the year. Therefore, this member of the public in the college building will be exposed to 125 new fuel shipments, 80 spent fuel movements, the shipment of 31 NDT radiography sources and 15 LLW shipments. It has been conservatively assumed that all new fuel shipments occur during term time, resulting in exposure to persons in the college building. No account has been taken of shielding that would be provided by the college building.

Dwelling scenarios (local railhead and generic UK road scenario)

The nearest railhead to the HPC site is at Bridgwater. Assessment of doses received whilst transferring flasks of spent fuel from lorry to rail wagon at the railhead will be calculated assuming that there is one loaded flask transport per reactor per week – i.e. it has been assumed that two flasks will be transferred at the rail head per week. A flask may be parked at the railhead for a few hours awaiting transfer to the wagon, or awaiting a second flask on the train. The whole process of loading a train with flasks would take up to four hours. The nearest dwelling where occupants are exposed to this activity is approximately 20 m from a loaded rail wagon or lorry.

The generic UK scenario for radioactive transport is appropriate for any road route taken by a conveyance on any part of a journey and not specific to Cannington or Bridgwater. It is conservatively assumed that the member of the public remains in a house on this route, at a distance of 5 m from the road at all times. However, it is unlikely that all material types are transported past this same house with this same person at 5 m from the road at all times. Therefore, this occupant of the house is taken to be exposed only to transports of one particular material type, either NDT radiography sources or new fuel or LLW or spent fuel, but not combinations of these.

5.2.4.2 Results of the Radiological Assessment for the Transport of Radioactive Materials to and from Hinkley Point C and Assessment against Dose Criteria

Details of the results, with a breakdown of the prospective doses for each type of transport past the bus stop, college, railhead and house on a generic UK road route are given in Appendix Table G4 and are discussed below.

The highest total annual dose is estimated to be received by a member of the public living adjacent to the Bridgwater railhead and exposed to spent fuel flasks being taken from HPC. It is predicted that should this scenario occur, doses in the region of 2.0 µSv y^{-1} could be received.

Should they be exposed to all four material transport scenarios (NDT sources, spent fuel, new fuel, LLW) a member of the public standing at a bus stop at the junction in Cannington could receive a dose of up to 1.8 µSv y^{-1} whilst the total dose to an occupier in the college in Cannington, close to the junction where transport of these four types of materials might need to stop is estimated as 0.07 µSv y^{-1}.

Members of the public living in a house close to a generic UK road transport route have been conservatively estimated to receive doses of up to 1.67 µSv y^{-1} from transports of new fuel to HPC (but less from transports of other materials).

Doses due to transport of spent fuel only range from 0.01 µSv y^{-1} (for an occupier in the college in Cannington) to 2.0 µSv y^{-1} (for the habitation near the Bridgewater railhead). The latter is generally comparable with the maximum individual dose due to the movement of nuclear fuel flasks of 6 µSv y^{-1} reported in NRPB-W66[84]. The NRPB assessment was carried out for a member of the public living 20 m away from a rail head, a scenario that makes it likely that it was the Bridgwater railhead that was considered (most other railheads are in more isolated areas or on the sites themselves).

The results of the transport assessment for HPC are summarised in the Table 22 below.

Table 22: Prospective public doses due to radioactive transports to and from HPC

Scenario	Dose due to transport $\mu Sv\ y^{-1}$	Dose without spent fuel transport $\mu Sv\ y^{-1}$
Habitation near Bridgwater railhead	2.00	zero
Habitation on generic UK road route close to road. Assumes only one type of transport passes.	1.67 (assumes worst case of new fuel transport only)	1.67 (assumes worst case of new fuel transport only)
Bus stop in Cannington	1.8	1.4
College in Cannington	0.07	0.06

The prospective doses for the exposure scenarios considered, including transport of spent fuel from HPC, therefore range from 0.07 $\mu Sv\ y^{-1}$ (for the occupier in the college) to 2.00 $\mu Sv\ y^{-1}$ (for the habitation at the railhead). Current assumptions are that EDF will store spent fuel on the HPC site in an Interim Spent Fuel store. Therefore, the prospective doses due to transport of materials to and from HPC would be reduced to within the range of 0.06 $\mu Sv\ y^{-1}$ (due to transport of NDT sources plus new fuel and LLW past the college) to 1.67 $\mu Sv\ y^{-1}$ (due to transport of new fuel past the house close to a road elsewhere). The dose at the habitation close to the Bridgwater railhead would fall to zero.

The transport scenarios considered here are conservative and actual realised doses are likely to be up to an order of magnitude lower than those estimated, especially for the house dweller scenarios.

These prospective dose values are significantly below the dose limit for members of the public in the Ionising Radiations Regulations 1999[16] of 1,000 $\mu Sv\ y^{-1}$ due to man-made sources, which is applicable to transport operations (Section 3.4.1.1).

6.0 MITIGATION OF IMPACTS

6.1 Construction Phase Impact Mitigation (radiological impacts on the public)

Investigations of the potential radiological contamination of soils on the HPC construction area are complete. In summary, no soil samples (including those from within previously disturbed ground) were found to be "radioactive" as defined by the relevant legislation[18,19,79] nor, in the majority of cases, in excess of normal background levels found in soils in the UK. Soils in the construction area site would therefore not be subject to regulatory controls for radioactive substance regulation.

Surface and groundwater samples contain K-40, a naturally occurring radionuclide. Low levels of tritium occur in groundwater in some areas of the construction footprint but below drinking water standards[(k).]

In view of these findings, a formalised public dose assessment due to HPC construction work has not been carried out. However, fugitive emissions of soil or water or the off-site transport or disposal of surplus soil, would be not expected to give rise to radiological impacts any more significant than those from any other form of large-scale construction project in the Hinkley Point area. From the standpoint of radiological impacts on the public from construction, no further mitigation measures over and above those required in any standard large-scale construction project (such as dust control, wheel washes, correct routing and management of waste water etc.) would be required.

6.2 Operational Phase Impact Mitigation

6.2.1 Mitigation of Discharges

It has been shown that prospective doses to all age groups in the Critical Group ('Farming Family with marine and gaseous exposure' and including the infants who receive the highest prospective dose) from HPC discharges plus direct radiation are below the new source constraint of 300 µSv $y^{-1.}$ They are also the HPA-RPD recommendation of 150 µSv y^{-1} (established in Section 3.4.1.1). All members of the candidate critical groups ('Farming Family with marine and gaseous exposure' and 'Fishing Family with marine and gaseous exposure') would therefore be afforded the same level of protection.

The prospective doses due to the HPC discharges at the activity values used in the assessment (Tables 12 and 13, plus direct radiation from the waste stores in Section 5.2.2.5) are also below 10 µSv y^{-1}, the level at which the UK Government in its statutory guidance to the Environment Agency has stated that the Agency should not seek further progressive reductions in discharge limits that are in place (and presumably those that are being applied for) provided that the holder of the authorisation applies, and continues to apply, Best Available Techniques (BAT; Section 2.3.2).

Extensive demonstration of the use of best practical techniques (BAT) for mitigation of radioactive discharges has already been achieved for the EPR but remains an ongoing consideration throughout the rest of the design, operating (and eventually, decommissioning) phases[23,24]. Demonstration of BAT is a pre-requisite to demonstrating that doses due to discharges are ALARA[42]. The following sections provide a summary of the methods used to mitigate C-14 and tritium discharges for the EPR, as they have been developed to date.

6.2.2 C-14 Discharge Mitigation

C-14 discharges from a PWR occur in liquids and gases in a number of forms, including carbon dioxide and methane. In the EPR, C-14 is minimised at source by measures aimed at increasing the efficiency of nuclear fuel which reduces its production per unit of energy produced. C-14 is also produced from nitrogen dissolved in the coolant, itself derived from nitrogen cover gas used in certain plant systems. In the EPR, this nitrogen has replaced more usual use of hydrogen which, however, may present an explosion hazard. Out-gassing from liquids means the majority of C-14 is discharged to the environment in gaseous form, with only a relatively small proportion being discharged in liquid discharges or solid wastes. C-14 discharged in gaseous form has a lower radiological impact, per unit discharged, than discharged in liquid form.

The C-14 cannot be recovered and converted to solid form from the gaseous or liquid waste streams by conventional methods of filtration, evaporation. Uptake of C-14 occurs on ion exchange resins but systems are not optimised for the removal of this particular isotope in this way. C-14 has a half-life of 5,730 years, so hold-up and decay is not a feasible abatement method. No practicable abatement techniques for the removal of C-14 from liquid and gaseous discharges have been identified, other than the removal of C-14 from liquid discharges which occurs as a result of primary coolant treatment processes which are aimed at removal of other species for operational and nuclear safety purposes. The proposed operation of the EPR is consistent with international best practice for PWRs with respect to the management of effluents containing C-14 (IAEA, 2004)[85].

6.2.3 H-3 Discharge Mitigation

Tritium makes up the bulk of the total radioactivity discharged in liquids and about 10% of that discharged in gases from HPC (Tables 14 and 15) but makes only a small contribution to the doses due to discharges from HPC (see Table 18). In liquid discharges from the EPR, the majority of the tritium is present as tritiated water liquid and in gases as tritiated water vapour. Most tritium present as tritium gas in the gaseous treatment systems is partitioned into the aqueous phase using a specific ‘catalytic recombiner’.

In the EPR, tritium is minimised at source by a number of measures. These include high integrity of fuel cladding, optimisation of coolant pH, combined with the use of burnable poisons in some fuel rods and reducing the use of secondary neutron sources[86]. The majority of tritium is discharged into the environment in liquid discharges. H-3 has a low radiological impact, and discharge in liquid form has lower radiological impact per unit discharged than discharge in gaseous form.

Tritium cannot be recovered and contained from these waste streams by conventional methods of filtration, evaporation or ion exchange. The tritium has a half-life of 12.3 years so abatement by hold-up and decay is not possible, especially given the volumes of liquid and gas that need to be managed. No practicable abatement techniques for the removal of tritium from liquid and gaseous discharges have been identified. The proposed operation of the EPR is consistent with international best practice for PWRs with respect to the management of effluents containing tritium[85].

6.2.4 Discharge Mitigation for Iodine Isotopes

Section 5.2.2.4 (Table 16) has shown that a small proportion of prospective doses is due to liquid and gaseous discharges of iodine isotopes. Isotopes of iodine are primarily contained within the fuel by the Zircaloy fuel cladding but any small defects in this allow small amounts of iodine isotopes to transfer to the reactor coolant. Stringent manufacturing standards for the fuel and control of primary circuit chemistry ensure that such leaks are minimised at source. Once in the liquid coolant, iodine nuclides will be subject to abatement on filters and demineralisers in the liquid effluent treatment systems. The French OPEX on the liquid discharges of iodines (PCER)[24] indicate that the use of demineralisers is a proven and effective abatement technique. Iodine nuclides passing into the gas phase are removed in charcoal absorbers in various gaseous radioactive treatment systems, including those serving building areas and those treating off-gas from primary coolant (charcoal absorbers are designed specifically to remove iodine and used in all nuclear power plant designs).

6.3 Mitigation of Direct Radiation

The current proposed location for the Interim Storage Facility for Spent Fuel and for the ILW store is on the edge of the site, close to the site boundary. These buildings would be designed to ensure that areas in the immediate vicinity would remain unclassified under the IRRs, that is with a dose rate below 1,000 µSv y^{-1}. Based on this bounding assumption of dose on the outside of these waste stores due to the materials stored or handled inside, the prospective dose to a member of the public walking past the stores daily over a year is 1.5 µSv y^{-1}. However, taking account of the fall off in dose at the extremities of the daily walk, the dose would fall below this value (Section 5.2.2.5). Furthermore, the estimated dose is based on a conservative source term (1,000 µSv y^{-1} at the walls of the store, the maximum that would be permissible in any such design). The actual shielding of the store would probably reduce dose rates outside to below this and thus also reduce the dose to any members of the public outside the site boundary and walking past the stores to below those calculated in Section 5.2.2.5.

6.4 Mitigation for Transport

Prospective doses to members of the public from the transport of radioactive materials to and from the proposed HPC site are dominated by the transport of spent fuel – based on the assumption that the spent fuel would be transported off-site and stored in an off-site facility. Whilst this predicted annual dose is relatively low, up to 2 µSv y^{-1}, and well below the public dose limit, doses from this scenario can be eliminated by retaining an on-site Interim Storage Facility (ISF) for the spent fuel, as is currently assumed (Section 5.2.4).

7.0 CUMULATIVE AND ADDITIVE IMPACTS

7.1 Assessment of Cumulative Radiological Impact on Humans

The methodology used to determine the radiological impact resulting from discharges from HPA and HPB is that described in Sections 3 and 5. The discharges from HPA and HPB used for these assessments are presented in the Table 23 and Table 24 (those for HPA taking account of its current decommissioning phase). These are based on discharges at the current authorised limits (rather than actual discharges) and will therefore yield conservative dose values for radiological impacts from these two sites. In addition, the cumulative impacts estimated in the current section assume that the discharges from these two sites continue for the next 60[n] years, that is, in parallel with those from the planned HPC EPR reactors. This leads to some uncertainties, and probably conservatism, in the final cumulative doses estimated (and Total dose for the site) since Hinkley Point B will have ceased operation at power and will have entered a decommissioning phase well within the operational lifetime of HPC. Furthermore, Hinkley Point A will be even further advanced in its current decommissioning programme.

Table 23: Annual gaseous discharge limits HPA and HPB

Radionuclide	Annual gaseous discharge limits (GBq y^{-1})	
	HPA	HPB[o]
H-3[k]	1,500	12,000
C-14	600	3,700
Ar-41	-	100,000
I-131	-	1.5
Co-60	-	0.1
S-35	-	350
beta[p]	0.15	1

Table 24: Annual liquid discharge limits HPA and HPB

Radionuclide	Annual liquid discharge limits (GBq y^{-1})	
	HPA	HPB
H-3[q]	1,800	650,000
Co-60	-	10
Cs-137	1,000	100
S-35	-	2,000
Other radionuclides[r]	700	80

[n] Individual dose assessments are calculated following 50 years of continuous discharges. Build-up assessments are calculated following 60 years of continuous discharges.
[o] Hinkley Point B has an on-site incinerator used to burn oils. In the assessment, discharges from this are not considered as they are minor compared with reactor operation. Moreover the limits for reactor discharges are used for the assessment, although they have never been near those authorised.
[p] Assumed to be Co-60 for HPA and HPB discharges
[q] 0.025% of H-3 assumed to be discharged as Organically Bound Tritium (OBT).
[r] Assumed to be Cs-134 for HPA and HPB

7.1.1 Cumulative Impact on the Candidate Critical Groups from HPA and HPB plus HPC

The doses to the two candidate critical groups of the farming and fishing families, assumed to reside at the same locality and where maximum exposure to airborne and deposited activity from HPC gaseous discharges occurs, but due specifically to discharges from HPA (Table 23) and HPB (Table 24) have been estimated. The methodology was the same as that used to estimate doses to these two candidate critical groups due to discharges from HPC.

In order to model discharges of Organically Bound Tritium (OBT) from Hinkley Point B, a separate radionuclide was created in PC CREAM, with the physical attributes (half-life and emissions) of tritium but with marine concentration factors as for C-14. Note that OBT is not expected to appear in discharges from PWRs.

7.1.1.1 Cumulative Effects for the 'Farming Family with marine and gaseous exposure'

The doses to the 'Farming Family with marine and gaseous exposure' considered in the current assessments (Section 3.4.1.2) due to liquid and gaseous discharges from HPA (and assuming CEFAS[53] consumption rates) were calculated as 0.6, 0.5 and 0.6 µSv y^{-1} for adults, children and infants, respectively. For this same family exposed to liquid and gaseous discharges from HPB (and again assuming CEFAS[53] consumption rates) the doses were calculated as 3.5, 4.4 and 12 µSv y^{-1} for adults, children and infants, respectively.

With those due to liquid and gaseous discharges from HPC (Section 5.2.2.2) the cumulative Hinkley Point Site doses to the 'Farming Family with marine and gaseous exposure' are given in Table 25. These cumulative prospective doses conservatively assume the HPA and HBP reactor sites discharge at the authorised limits and HPC discharges at values in Tables 12 and 13, all simultaneously.

Table 25: Cumulative prospective doses to the 'Farming Family with marine and gaseous exposure' exposed to liquid and gaseous discharges from Hinkley Points A, B and C

Age group	Predicted cumulative dose µSv y^{-1}
Adult	6.8
Child	7.3
Infant	17.2

A breakdown of how these cumulative doses are built up from those due to the discharges from HPC, HPA and HPB is shown in Figure 7. Overall, infant members of this group receive the greatest dose and this is dominated by exposures through terrestrial pathways (99% of the cumulative prospective dose). C-14 and S-35 dominate the cumulative doses to all age groups and make up 40% and 53% respectively of the cumulative dose to the infant, mainly through the consumption of milk and milk products. Figure 7 shows the dose from S-35 is due solely to discharges of this isotope from the gas cooled reactor HPB, with a small amount from HPA. The small dose contribution from the marine discharges due to the consumption of marine foods is dominated by C-14 and OBT, making-up, respectively, 50% and 32% of the dose via this route.

7.1.1.2 Cumulative Effects for the 'Fishing Family with marine and gaseous exposure'

The doses to the 'Fishing Family with marine and gaseous exposure' considered in the current assessment (Section 3.4.1.2) due to liquid and marine discharges from HPA (and assuming CEFAS[53] consumption rates) were calculated as 1.2, 0.4 and 0.5 µSv y^{-1} for adults, children and infants respectively. For this same family exposed to liquid and gaseous discharges from HPB (and again assuming CEFAS[53] consumption rates) the doses were calculated as 3.7, 3.8 and 9.4 µSv y^{-1} for adults, children and infants, respectively.

With those due to liquid and gaseous discharges from HPC (Section 5.2.2.3) the cumulative Hinkley Point Site doses to the 'Fishing Family with marine and gaseous exposure' are given in Table 26 below. These cumulative prospective doses conservatively assume the HPA and HBP reactor sites discharge at the authorised limits and HPC discharges at the activity values in Tables 12 and 13, all simultaneously.

Table 26: Cumulative prospective dose to the 'Fishing Family with marine and gaseous exposure' exposed to liquid and gaseous discharges from Hinkley Points A, B and C

Age group	Predicted cumulative dose µSv y^{-1}
Adult	7.8
Child	6.5
Infant	13.2

A breakdown of how these cumulative doses are built up from those due to the discharges from HPC, HPA and then from HPB is shown in Figure 8. Overall, the infant members of the 'Fishing Family with marine and gaseous exposure' receive the greatest dose from all sources. Although this is classed as a fishing family, the dose to all age groups is dominated by contributions from the terrestrial pathways which, in the case of the infant make up 98% of the cumulative dose received. C-14 and S-35 again dominate these cumulative doses to all age groups and make up 41% and 55% respectively of that to the infant age group. This is mainly through the consumption of milk and milk products.

7.1.1.3 Critical Group for Hinkley Point Site and Assessment of Prospective Doses against the Site Dose Constraint

The site dose constraint of 500 µSv y^{-1} for the maximum dose to people that may result from discharges from a site applies to the cumulative dose from the discharges (direct radiation is not included) from all sources at a single location.

A summary of the prospective doses to members of the two candidate critical groups due to Hinkley Point Site discharges is shown in Table 27 below:

Table 27: Summary of prospective doses to candidate critical groups due to Hinkley Point Site discharges

Age group	'Farming Family with marine and gaseous exposures'	'Fishing Family with marine and gaseous exposures'
Adult	6.8 $\mu Sv\ y^{-1}$	7.8 $\mu Sv\ y^{-1}$
Child	7.3 $\mu Sv\ y^{-1}$	6.5 $\mu Sv\ y^{-1}$
Infant	17.2 $\mu Sv\ y^{-1}$	13.2 $\mu Sv\ y^{-1}$

Table 27 shows that the highest prospective doses due to Hinkley Point Site are 17.2 $\mu Sv\ y^{-1}$ to the infant and 7.3 $\mu Sv\ y^{-1}$ to the child in the 'Farming Family with marine and gaseous exposures'. The dose to the adult in the 'Fishing Family with marine and gaseous exposure' is marginally higher than that to the adult in the farming family. However, taking account of the differences in doses, the assessment shows that the '**Farming Family with marine and gaseous exposures'** is the **Critical Group** due to Hinkley Point Site discharges.

The prospective doses to this Critical Group are well below the site constraint of 500 $\mu Sv\ y^{-1}$. Doses to all other members of the candidate critical groups ('Farming Family with marine and gaseous exposure' and 'Fishing Family with marine and gaseous exposure') would therefore also be well below this site constraint.

Figures 7 and 8 show that the cumulative prospective doses to both candidate critical groups are dominated by contributions from S-35 and from C-14. S-35 makes up the bulk of the dose to the infant, whilst C-14 dominates that to the child and adult. All of the dose due to the S-35 is from the HPB reactor site. Cumulative doses from C14 are due mainly to the EPR; data in Section 6.2.2 show that methods to mitigate the discharges of this from the EPR are consistent with best international practice and subject to on-going assessments to ensure compliance with the requirements of BAT.

Figures 7 and 8 show that the other main contributors to the cumulative prospective doses are tritium, iodine and fission products. The bulk of the dose from the tritium and iodine to age members in both candidate critical groups is due to the discharges from the HPC, whilst that from the fission products is due mainly to the HPA and HPB reactor sites. These results are expected on the basis of the overall design and operation of the HPC and HPB reactors and the decommissioning operations at HPA.

Figure 9 shows a breakdown of the prospective cumulative doses due to liquid and gaseous discharges from HPA, HPB and HPC to each of the age groups in the **Critical Group** of the '**Farming Family with marine and gaseous exposure**' (as a percentage of the cumulative dose for each age group). A generally similar breakdown applies to the three age groups in the 'Fishing Family with marine and gaseous exposure'. Thus, discharges from HPA account for between about 3% to 15% of the cumulative prospective dose to all three age groups, those from HPB account for between about 47 and 70% and those from HPC account for between about 26 and 40% of the cumulative prospective dose. Overall, the largest proportion of the prospective cumulative dose to all members of both candidate critical groups is due to liquid and gaseous discharges from the current operational HPB AGR. Once this enters its decommissioning phase in about 2016 the cumulative Hinkley Point site doses will decrease and, realistically, only those due to the operational HPC EPRs would need be considered.

7.1.2 Total Dose to an Individual on the Hinkley Point Site

Total dose takes into account historical and future Hinkley Point site discharges, and future direct radiation from other facilities on the Hinkley Point Site in addition to the future discharges from HPC and the on-site impacts of discharges from elsewhere. This grand total represents the ‘Total Dose’ to an individual on the Hinkley Point Site, which can be compared with the public dose limit.

Retrospective critical group doses as a result of discharges from the existing Hinkley Point Site are assessed annually in the RIFE reports. These were presented in Table 4 for the years 2001 to 2007. The highest retrospective dose in recent years was 40 µSv to consumers of seafood. Besides that due to discharges from HPA and HPB, this dose includes contributions from other establishments that discharge into the Bristol Channel. In particular these are from the GE Healthcare Cardiff site, which produces H-3 and C-14 for medical research, and also historical contributions from Berkeley, Oldbury, Sellafield and Chernobyl. Direct radiation dose from the existing HPA and B stations was measured to be 4 µSv y^{-1} in 2007 as reported in RIFE-13[55]. This value is appropriate to use as the future direct radiation dose for the Hinkley Point Site as it was determined that the direct radiation dose at the closest dwelling to HPB would be 0.14 nSv, and as HPA and B are decommissioned, direct radiation doses from these facilities should reduce.

Summing the retrospective critical group dose from all the above sources with the direct radiation dose and the future exposures critical group dose (from 50 years of combined discharges from the Hinkley Point Site viz the maximum cumulative dose of 17.2 µSv y^{-1} in Table 27) results in the Total Dose for an individual on site of 61 µSv, equivalent to 6.1% of the public dose limit.

7.1.3 Cumulative Collective Dose

All of the collective doses discussed below are expressed as per year of discharge and truncated at 500 years.

The collective doses calculated to the UK, European and World populations from HPA gaseous and liquid discharges are presented in Table 28.

Table 28: Collective doses to the UK, European and World populations from HPA discharges

HPA discharges	Collective Population		
Collective dose (Man Sv)	UK	Europe	World
Gaseous discharges	0.155	1.32	10.6
Liquid discharges	0.0039	0.022	0.022
Total Collective dose due to HPA discharges	0.159	1.34	10.6

Collective doses calculated to the UK, Europe and World populations of from HPB gaseous and liquid discharges are presented in Table 29.

Table 29: Collective doses to the UK, European and World populations from HPB discharges

HPB discharges	Collective Population		
Collective dose (Man Sv)	UK	Europe	World
Gaseous discharges	1.4	9.2	65.1
Liquid discharges	0.00065	0.0046	0.031
Total Collective dose due to HPB discharges	1.4	9.2	65.1

With those due to HPC (Section 5.2.2.7) the collective doses to the UK, European and World populations due to gaseous discharges to the atmosphere from the Hinkley Point Site were calculated to be 1.9, 13.5 and 100.3 Man Sv, respectively. With those due to HPC, the collective doses to the UK, European and World populations due to liquid discharges from the Hinkley Point Site were calculated to be 0.025, 0.23 and 2.2 Man Sv, respectively. The final results for the cumulative collective dose assessment for the Hinkley Point site and the calculated total *per caput* doses are presented in Table 30.

Table 30: Collective doses to the UK, European and World populations from Hinkley Point Site discharges

HP Site	Collective Population		
Collective dose (Man Sv)	UK	Europe	World
Gaseous discharges	1.9	13.5	100.3
Liquid discharges	0.025	0.23	2.2
Total Collective dose due to Hinkley Point Site marine and gaseous discharges	1.9	13.7	102.5
Average per caput dose (nSv)	UK	Europe	World
Gaseous discharges	34.5	19.3	10.0
Liquid discharges	0.45	0.33	0.22
Total *per caput* dose due to Hinkley Point Site marine and gaseous discharges	34.5	19.6	10.3

The collective dose to the UK population (truncated at 500 years) in Table 30 of 1.9 Man Sv per year of discharge from Hinkley Point site is similar to a guideline of about 1 Man Sv per year of discharge that the IAEA considers sufficiently low to allow a source or practice to be exempted from regulatory control (Section 3.4.1.1).

The *per caput* doses from all Hinkley Point Site discharges (per year of discharge and truncated at 500 years) have been calculated to be 34.5, 19.6 and 10.3 nSv y^{-1} discharge for populations of the UK, Europe and the World respectively. Those to the World population are therefore in the range of a ‘few nSv’ that, in the EA interim guidance document on assessment of prospective public doses, are stated should be ignored in the decision making process, as the associated risks are miniscule with the contribution to total doses to individuals being insignificant. Those to the UK and European populations are above this ‘few nSv’ range but still well below those of a ‘few µSv’ that can be considered as ‘trivial’ and well below those in the higher end of the µSv range that the EA state might require some additional consideration (Section 3.4.1.1).

The collective dose due discharges from the Hinkley Point Site are all dominated by the C-14 present in gaseous discharges, which accounts for between 75% and practically 100% of the cumulative collective doses for all of the populations considered. However, these are all much lower than that from naturally occurring C-14 to the UK population alone (about 480 man Sv y^{-1}; European Commission)[48]. Similarly, the *per caput* doses from these gaseous discharges (of up to 34.5 nSv y^{-1}) are all much smaller than that due to naturally occurring C-14 to the UK population of the order of 8.8 µSv y^{-1}[(48)].

C-14 contributes to the bulk of the dose due to the Hinkley Point Site liquid discharges as well, although there is no data on natural sources and doses against which to compare this.

A breakdown of the collective doses for the UK, European and World populations due to liquid and gaseous discharges from HPA, HPB and HPC is shown in Figure 10. This shows that HPA contributes to between about 8% (for the UK) and 10% (for the World) of the cumulative collective dose, whilst HPB contributes to between 64 and 71% and HPC contributes to between 20 and 26%. Thus, the majority of the cumulative Hinkley Point Site collective dose to the UK, European or World populations is due to the liquid and gaseous discharges from the currently operating HPB reactor. Like those to the candidate critical groups (Section 7.1.1.3) cumulative doses from the Hinkley Point site will therefore be expected to decrease when this reactor ceases operation in 2016 and, like HPA, enters a decommissioning phase.

7.1.4 Build-Up due to Cumulative Hinkley Point Site Discharges

Table 31 (over/) presents the results for the soil concentration at the area off-site with the highest concentration at year 60 due to all Hinkley Point Site gaseous discharges to the atmosphere.

The results for the activity concentration in the seawater and seabed sediment off the coast of Hinkley Point at year 60 from all Hinkley Point Site marine discharges are presented in Table 32 (over/).

Table 31: Soil concentration at the area off site with the highest concentration at year 60 from all Hinkley Point gaseous discharges to the atmosphere

Nuclide	Air Concentration Bq m^{-3}	Soil Concentration Bq kg^{-1}
H-3	$6.1\ 10^{-01}$	-*
C-14	$1.63\ 10^{-01}$	-*
S-35	$6.5\ 10^{-03}$	$2.0\ 10^{-01}$
Ar-41	$1.9\ 10^{-00}$	-*
Co-58	$3.6\ 10^{-06}$	$8.8\ 10^{-05}$
Co-60	$2.7\ 10^{-05}$	$1.5\ 10^{-02}$
Kr-85	$3.7\ 10^{-01}$	-*
I-131	$4.8\ 10^{-05}$	$1.1\ 10^{-03}$
I-133	$2.6\ 10^{-05}$	$6.3\ 10^{-05}$
Xe-131m	$8.0\ 10^{-03}$	-*
Xe-133	$1.7\ 10^{+00}$	-*
Xe-135	$5.3\ 10^{-01}$	-*
Cs-134	$3.3\ 10^{-06}$	$7.6\ 10^{-04}$
Cs-137	$3.0\ 10^{-06}$	$5.9\ 10^{-03}$

* Soil concentrations not calculated for noble gases H-3 or C-14.

Table 32 Activity concentration in the seawater and seabed sediment off the coast of Hinkley Point at year 60 from all Hinkley Point Site marine discharges

Nuclide	Activity concentrations (Bq l^{-1}) in unfiltered seawater	Activity concentrations (Bq kg^{-1}) in sediment
H-3	$8.38\ 10^{+00}$	$5.69\ 10^{+00}$
C-14	$2.00\ 10^{-03}$	$1.19\ 10^{-01}$
Mn-54	$5.34\ 10^{-06}$	$4.03\ 10^{-05}$
Ni-63	$2.01\ 10^{-05}$	$3.60\ 10^{-03}$
Cr-51	$8.28\ 10^{-07}$	$5.28\ 10^{-07}$
Co-60	$1.65\ 10^{-04}$	$6.83\ 10^{-03}$
Co-58	$3.56\ 10^{-05}$	$6.20\ 10^{-05}$
Ag-110m	$1.12\ 10^{-05}$	$1.17\ 10^{-05}$
Sb-124	$8.21\ 10^{-06}$	$2.10\ 10^{-06}$
Sb-125	$1.68\ 10^{-05}$	$6.60\ 10^{-05}$

I-131	$3.89\ 10^{-07}$	$4.46\ 10^{-09}$
S-35	$1.78\ 10^{-02}$	$4.82\ 10^{-03}$

* indicates a daughter product

The prospective dose to a future construction worker off-site as a consequence of the build-up of nuclides as a result of emissions from HPA, HPB and HPC has been calculated to be $1.8\ 10^{-2}$ µSv y^{-1}. Approximately 100% of this dose is due to external exposure from the ground. The nuclide that contributes the most to external exposure is Co-60, which accounts for 89% of external dose.

The annual exposure due to the future use of the marine environment resulting from the cumulative discharges from HPA ,HPB and HPC is likely to be associated with commercial fishing and leisure activities. Therefore, the dose to members of the public from future use of the sea has been assessed as the Fishing Family group and therefore taking account of the total marine dose only.

The individual total marine doses due to build-up to the 'Fishing Family with marine and gaseous exposure' from HPA were calculated as 0.97, 0.16 and 0.039 $\mu Sv\ y^{-1}$ for adults, children and infants respectively.

The individual total marine doses due to build-up to the 'Fishing Family with marine and gaseous exposure' from HPB were calculated as 0.78, 0.21 and 0.082 $\mu Sv\ y^{-1}$ for adults, children and infants respectively.

Taking into account marine dose from build-up due to HPC discharges (Section 5.2.2.9) the prospective dose due to build-up to the 'Fishing Family with marine and gaseous exposure' from all marine discharges from the Hinkley Point Site was therefore calculated to be 2.8, 0.67 and 0.24 $\mu Sv\ y^{-1}$ for adults, children and infants respectively. This assumes CEFAS[53] ingestion rates.

These cumulative prospective doses due to build-up from the Hinkley Point Site are well below the annual public dose limit of 1,000 $\mu Sv\ y^{-1}$ or the typical average exposure to an individual from all sources of 2,700 $\mu Sv\ y^{-1}$.

7.2 Assessment of Cumulative Radiological Impact on Non-Human Species

7.2.1 HPA, HPB and Cumulative Hinkley Point Site Impact for Habitat 1

The surveys showed that the majority of the ERICA default organisms were present in all four Habitats but (as for the HPC assessment) for completeness, all of the ERICA default organisms were included and modelled, regardless of whether they had been identified or not.

7.2.1.1 HPA

For HPA, the risk quotients for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA[28] organisms and the additional custom organisms, badger and bat, based on a screening value of 10 $\mu Gy\ h^{-1}$. The maximum RQ was 5.24 10^{-5} for badgers. The associated dose for these organisms is 5.24 10^{-4} $\mu Gy\ h^{-1}$.

7.2.1.2 HPB

For HPB, the risk quotients for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms and the additional custom organisms, badger and bat, based on a screening value of 10 $\mu Gy\ h^{-1}$. The maximum RQ was 3.37 10^{-4} for badgers. The associated dose for these organisms is 3.37 10^{-3} $\mu Gy\ h^{-1}$.

Doses and RQs for discharges of noble gases from HPB were also calculated. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 1, caterpillars receive the highest dose rate of 1.2 10^{-3} µGy h^{-1}.

7.2.1.3 Habitat 1 Cumulative from Hinkley Point Site

For the cumulative Hinkley Point Site, the risk quotients for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms and the additional custom organisms, badger and bat, based on a screening value of 10 µGy h^{-1}. The maximum RQ was 8.06 10^{-4} for badgers. The associated dose for these organisms is 8.06 10^{-3} µGy h^{-1}.

Doses and RQs for discharges of noble gases from cumulative discharges were also calculated. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 1, caterpillars receive the highest cumulative dose rate of 2.70 10^{-3} µGy h^{-1}.

7.2.2 HPA, HPB and Cumulative Hinkley Point Site Impact for Habitat 2

7.2.2.1 HPA

For HPA, the risk quotients for liquid releases to the marine environment on marine organisms were determined for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 3.46 10^{-4} for reptiles. The associated dose for these organisms is 3.46 10^{-3} µGy h^{-1}.

7.2.2.2 HPB

For HPB, the risk quotients for liquid releases to the marine environment on marine organisms were determined for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum RQ was 4.70 10^{-5} for reptiles. The associated dose for these organisms is 4.70 10^{-4} µGy h^{-1}.

7.2.2.3 Habitat 2 Cumulative from Hinkley Point Site

For the cumulative Hinkley Point Site, the risk quotients for liquid releases to the marine environment were determined for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum RQ was 5.20 10^{-4} for reptiles. The associated cumulative dose rate to these organisms is 5.20 10^{-3} µGy h^{-1}.

7.2.3 HPA, HPB and Cumulative Hinkley Point Site Impact for Habitat 3

7.2.3.1 HPA

For HPA, the RQs for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms and the additional custom organisms, badger and bat, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 1.53 10^{-5} µGy h^{-1} for badgers. The associated dose for these organisms is 1.53 10^{-4} µGy h^{-1}. RQs and doses for marine organisms have been presented in Section 7.2.2.1.

7.2.3.2 HPB

For HPB, the RQs for gaseous releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms and the additional custom organisms, badgers and bat, based on a screening value of 10 µGy h^{-1}. The maximum RQ was 1.22 10^{-4} for badgers. The associated dose for these organisms is 1.22 10^{-3} µGy h^{-1}. RQs and doses for marine organisms are presented in Section 7.2.2.2.

Doses and RQs for discharges of noble gases from cumulative discharges were also calculated. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 3, Caterpillars receive the highest dose rate of 4.3 10^{-4} µGy h^{-1}.

7.2.3.3 Habitat 3 Cumulative from Hinkley Point Site

For the cumulative Hinkley Point Site, the risk quotients for atmospheric releases to the terrestrial environment on terrestrial organisms were determined for each of the default ERICA organisms based on a screening value of 10 µGy h^{-1} with the additional custom organisms, badger and bat. The maximum risk quotient was 1.62 10^{-4} for badgers. The associated dose for these organisms is 1.62 10^{-3} µGy h^{-1}. RQs and doses for marine organisms are presented in Section 7.2.2.3.

Doses and RQs for discharges of noble gases from the Hinkley Point Site were determined. Organisms from R&D128[27] were chosen for their similarity to organisms studied in ERICA. For Habitat 3, Caterpillars receive the highest cumulative dose rate of 5.16 10^{-4} µGy h^{-1}.

7.2.4 HPA, HPB and Cumulative Hinkley Point Site Impact for Habitat 4

7.2.4.1 HPA

For HPA, the RQs for freshwater organisms were calculated for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 3.02 10^{-2} for insect larvae. The associated dose rate to these organisms is 3.02 10^{-1} µGy h^{-1}.

Organisms common to both Habitat 1 and Habitat 4 include amphibians, birds, gastropods and mammals. The dose rates from terrestrial and freshwater exposures due to gaseous discharges to these organisms are 2.37 10^{-3} µGy h^{-1}, 2.56 10^{-3} µGy h^{-1}, 1.52 10^{-1} µGy h^{-1} and 2.64 10^{-3} µGy h^{-1} respectively.

7.2.4.2 HPB

For HPB, the risk quotients for freshwater organisms were determined for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 1.84 10^{-1} for insect larvae. The associated dose rate to these organisms is 1.84 µGy h^{-1}.

Organisms common to both Habitat 1 and Habitat 4 include amphibians, birds, gastropods and mammals. The dose rates from terrestrial and freshwater exposures due to gaseous discharges to these organisms are 1.99 10^{-2} µGy h^{-1}, 2.11 10^{-2} µGy h^{-1}, 9.28 10^{-1} µGy h^{-1} and 2.16 10^{-2} µGy h^{-1} respectively. The doses do not include those from noble gases.

7.2.4.3 Habitat 4 Cumulative

For HP Site, the RQs for freshwater organisms were determined for each of the default ERICA organisms, based on a screening value of 10 µGy h^{-1}. The maximum risk quotient was 2.97 10^{-1} for insect larvae. The associated dose for these organisms is 2.97 µGy h^{-1}.

Organisms common to both Habitat 1 and Habitat 4 include amphibians, birds, gastropods and mammals. The summated dose from terrestrial and freshwater exposures due to gaseous discharges is 5.48 10^{-2} µGy h^{-1}, 5.03 10^{-2} µGy h^{-1}, 1.48 µGy h^{-1} and 6.22 10^{-2} µGy h^{-1} respectively. These doses do not include the dose from noble gases.

7.3 Overall Discussion of Cumulative Impacts for Hinkley Point Site

The highest prospective doses from all Hinkley Point Site discharges (assuming HPA and HPB continue to discharge at the current authorised rates and HPC discharges at the activity values in Tables 12 and 13) were estimated as 17.2 µSv y^{-1} to the infant and 7.3 µSv y^{-1} to the child in the 'Farming Family with marine and gaseous exposure'. Within the two critical groups, there is a marginally higher dose to the adult in the 'Fishing family with marine and gaseous exposures' but taking account of the differences in dose for each age group, the '**Farming Family with marine and gaseous exposures'** is considered as the **Critical Group** due to Hinkley Point Site discharges.

The prospective doses to this Critical Group are well below the site constraint of 500 µSv y^{-1}. Doses to all other members of the candidate critical groups ('Farming Family with marine and gaseous exposure' and 'Fishing Family with marine and gaseous exposure') would therefore also be similarly well below the site constraint.

The prospective doses to all members of the candidate critical groups from Hinkley Point Site discharges is less than 1% of the average dose to an individual in the UK population of 2,700 µSv y^{-1} from all sources of radioactivity and are also smaller than the man-made average contribution to this background of 410 µSv y^{-1}. The highest prospective dose of 17.2 µSv y^{-1} (to the infant in the 'Farming Family with marine and gaseous exposure') is comparable in magnitude to that received on a return flight from the UK to Europe (which is due to exposure to cosmic radiation). It is also comparable in magnitude to a chest x-ray which result in a dose of 20 µSv y^{-1}.

The *per caput* dose from all Hinkley Point Site discharges to the UK population was calculated to be 34.5 nSv y^{-1}. This can be compared to the average *per caput* dose to the UK population from all sectors of industry of 900 nSv y^{-1} [(65)]. It is marginally above the value of 'a few nSv' considered in relevant guidance (Environment Agency[42]) to be 'miniscule' but still well below those of a 'few µSv' that can be considered as 'trivial' and also well below those in the higher end of the µSv range that the guidance states might require some additional consideration.

Calculated doses to a future off-site construction worker or those using the marine environment (members in the Fishing Family) are well below the annual public dose limit of 1,000 µSv y^{-1} or the typical average exposure to an individual from all sources of 2,700 µSv y^{-1} and also below local terrestrial background values.

The biota in the freshwater habitat most affected by discharges from the Hinkley Point Site cumulative discharges was assessed to be insect larvae in Habitat 4, which would receive a dose of 2.97 µGy h^{-1}. This is below the ERICA screening value of 10 µGy h^{-1} and also therefore below the EA biota dose guideline of 40 µGy h^{-1}.

The total electrical output of the two HPC UK EPRs will be 3,300 MWe whilst the current electrical output from the remaining operational AGR is 860 MWe. Overall, therefore, the radiological impacts (assuming maximum design or authorised discharges) on a pro-rata basis of 'impact versus electrical output' from the UK EPR are estimated to be significantly less than those from the current HPB AGR.

8.0 RESIDUAL IMPACTS

The EPR design, has been developed using operational feedback from the wide experience of EDF and AREVA NP. The EPR is designed to reduce the production of solid waste and liquid and gaseous radioactive discharges. Principle objectives of the EPR design include:

"*minimise personnel dose exposure and radioactive releases and waste during normal operation*"[86]

"*the concentration and containment of radioactive emissions is a central objective of BAT* (OECD)" [86]

"*the equipment has to be designed, operated and maintained so as to limit the emissions of effluents. These emissions are to be, as much as possible, collected at their source, monitored and, if necessary, treated in such a way that consequential discharges are kept as low as reasonably possible. In any event, discharge limits will be set on the basis of the use of the best available technologies at an economically acceptable cost, and taking account of specific environmental characteristics of the sit*e." [86]

These objectives will reduce, as far as possible, the doses to the public, site workers and the environment incurred by the nuclear activities "as low as reasonable achievable" (ALARA) in accordance with UK regulatory principles, intergovernmental organisations such as the OECD and IAEA and the overall principles of BAT (Best Available Techniques) described in Section 2.3.1.

The following overarching goals were included in the design optimisation for the EPR:

- Reduction and control of tritium liquid discharges;
- Reduction and control of C-14 liquid discharges;
- Reduction of discharges of other radionuclides;
- Maximum recycling of boron (used in the primary circuit coolant);
- Optimisation of the primary circuit water quality (that can affect discharges);
- Overall reduction of chemical discharges;
- Minimisation at source;
- Selection of materials for construction.

This Technical Note has outlined the radiological assessments that have been undertaken for the Environmental Impact Assessment associated with the construction and operation of the HPC Reactors. The receptor groups and details and the overall outcomes of the assessment for the planned development are summarised below:

The source constraint for the maximum dose to people that may result from discharges from a new single discharges of 300 µSv y^{-1} applies to the dose from proposed discharges and direct radiation. Moreover, the Health Protection Agency (HPA-RPD) specifically advises the UK Government to select a value for the constraint for members of the public for new nuclear power stations that is less than 150 µSv y^{-1}.

For the Critical Group for HPC ('Farming Family with marine and gaseous exposures') prospective doses assessed due to continuous routine discharges (at values in Tables 12 and 13) plus direct radiation to adults, children and infants are, respectively, 2.7, 2.5 and 4.5 µSv y^{-1}. The prospective doses to all age groups in this Critical Group are much lower than the source constraint of 300 µSv y^{-1} and also below the HPA-RPD recommendation of 150 µSv y^{-1}. Doses assessed for all members in the other candidate critical group ('Fishing Family with marine and gaseous exposures') are of a similar order to those to the Farming family and also, therefore, well below the source constraint (and the HPA-RPD recommendation).

The prospective doses estimated due to HPC gaseous and liquid discharges (and direct radiation) to all age groups in both of the candidate critical groups are less than 10 µSv y^{-1}. This is the level at which the UK Government in its statutory guidance to the Environment Agency has stated that the Agency should not seek further progressive reductions in discharge limits that are in place provided that the holder of the authorisation applies and continues to apply best available techniques (BAT). It may be assumed that this also applies to discharges used in a prospective dose assessment.

All of the prospective doses to any member of either candidate critical group are much lower than the average dose to the UK population of 2,700 µSv y^{-1} from all sources of radioactivity and also lower than the average due solely to man-made sources of 410 µSv y^{-1}, nearly all of which is due to exposures to medical procedures[65]. The highest assessed dose due to HPC discharges (4.5 µSv y^{-1} to an infant) is comparable in magnitude to that received on a return flight within the UK (about 6 µSv/flight and due to exposure to cosmic radiation) or that received during a single medical X-ray (about 5 µSv).

The *per caput* dose from an annual HPC liquid and gaseous discharge to the UK population (and truncated at 500 years) was calculated to be 6.9 nSv y^{-1}. This is much smaller than the average *per caput* dose to the UK population from industry as a whole (including the nuclear industry) of 900 nSv y^{-1}. This *per caput* dose, and those assessed for Europe and the World (4.6 and 2.79 nSv y^{-1}) are all within the 'few nSv' range that, in its guidance on assessment of public doses, the Environment Agency states should be ignored in the decision making process, as the associated risks will be miniscule and the total doses to individuals will be insignificant.

The collective dose due to discharges from HPC at the values in Tables 12 and 13 (Man Sv^{-1} of discharge truncated at 500 years) was assessed at between 0.4 (for the UK and 24.6 (for the World) Man Sv y^{-1} discharge. These are all very much less than that due to naturally occurring C-14 to the UK population alone (480 Man Sv y h^{-1}). Per caput doses are also all significantly less than that due to naturally occurring C-14 to the UK (8.55 µSv y^{-1}).

The prospective doses due to a short-term gaseous discharge from HPC are of the order of 0.23 to 0.45 µSv y^{-1} and therefore about an order of magnitude lower than those predicted for continuous routine discharges and also well below the source constraint of 300 µSv y^{-1} or the dose limit of 1,000 µSv y^{-1} (that are the appropriate criteria against which to assess doses due to short-term discharges). Short-term liquid discharges would not occur.

The highest annual dose to an individual due to transport of materials associated with HPC would be received by a member of the public living adjacent to the Bridgwater railhead and exposed to spent fuel flasks being transferred off-site. It is predicted that should this scenario occur, doses in the region of 2 µSv y^{-1} could be received. This is much lower than the dose limit for members of the public from the Ionising Radiations Regulations 1999[16] of 1,000 µSv y^{-1} which is applicable to transport operations. With the implementation of the proposed on-site Interim Storage Facility for Spent Fuel, the actual doses due to transport of radioactive materials will be expected to be smaller than those estimated.

The freshwater habitat presented the worst-case dose rates for non-human species due to HPC discharges. The species most affected was calculated to be insect larvae, which would experience a dose rate of 0.833 µGy h^{-1}. This is below the ERICA screening value of 10 µGy h^{-1} and also therefore below the EA biota dose guideline for non-human species of 40 µGy h^{-1}:

The assessments all show that, when judged against a range of stringent internationally agreed criteria on Radiological Protection of Human and Non-human species, the assessed impacts from the liquid and gaseous discharges from HPC and other impacts due to site operations (transport, waste storage) are all very small, without additional mitigation being required over and above that in the current design.

For the Critical Group (‘Fishing Family with marine and gaseous exposures’) prospective doses due to discharges from Hinkley Point Site discharges to adults, children and infants are, respectively, 6.8, 7.3 and 17.2 µSv y^{-1}. The doses to all age groups in this Critical Group are much lower than the site constraint of 500 µSv y^{-1}. Doses to all members in the other candidate critical group (‘Fishing Family with marine and gaseous exposures’) are of a similar order to those to the Farming family and also, therefore, well below the site constraint. Infants receive the greatest dose of the three age groups and this is dominated by S-35 due to gaseous discharges from Hinkley B. These cumulative impacts assume that discharges from HPA and HPB continue for the next 50 years in parallel with those from the planned HPC EPR reactors. This leads to some uncertainties and probably conservatism in the Hinkley Point Site doses assessed because by about 2016 HPB will have entered its decommissioning phase and HPA will be even further advanced in its current decommissioning programme.

9.0 UNCERTAINTIES

The Environment Agency guidance on the assessment of assessment of prospective public doses[42] states that some consideration should be given to uncertainties in the methods used and results obtained.

For the dose assessments for the candidate critical groups (Section 5.2.2) there are two main sources of uncertainty, those inherent in the PC CREAM 98 model software and those associated with the input parameters (habits for the candidate critical groups).

PC CREAM 98 software uses annual averages for parameters such as weather, water flow and food consumption rates. This is considered adequate when assessing the consequences of routine releases integrated over long periods of time. Some of the sub-routines in the model assess doses at year1, 5 or 50 and the 60 year assumed for the operational life of the EPRs is not available as an option. However, in its guidance (paragraph 67) the Environment Agency[42] suggests an accumulation time of 50 years is usually selected for new plants or plants where it may be difficult to specify a closure date (which may the case for any life extension).

For Hinkley Points A and B, the dose assessments are based on current authorised limits and it is unlikely that either station will discharge close to or at these for the period over which the HPC UK EPRs will operate. For all the reactors, there may be some fluctuations in discharges but ultimately it is expected to be a downward trend in the discharges from HPA and HPB over the lifetime of HPC. Therefore the assessment based on current authorised limits for HPA and HPB is considered to be conservative.

Finally, in its guidance, the Environment Agency suggests that more formal and detailed review of results, input parameters etc. is required only if mean assessed critical group doses exceed 20 µSv y^{-1}. Those estimated for HPC are of the order of 3 µSv y^{-1}, those from Hinkley point Site being of the order of 10 µSv y^{-1}, implying no more formal assessment of uncertainties is warranted.

The effects of varying numerous parameters in the short-term assessment is included in the appendices of NRPB-W54[57]. The uncertainties can include discharge patterns and time, weather patterns during the discharge and pathways. However, the source term considered for HPC short-term discharges of monthly discharges within a 24 hour period is conservative and using the parameters assumed, the assessed doses are all very small (mostly less than 10% of those due to continuous discharges). Again, these assessed doses (up to 0.45 µSv y^{-1}) are well below the 20 µSv y^{-1} guideline that the Environment Agency suggests should require a more detailed assessment of uncertainty.

With respect to the collective dose assessment, since PC CREAM 98 (used for the assessment) was developed, the population and boundaries of Europe have changed and there have been population changes in the UK and World as well.

However, the collective doses and in particular the per caput doses estimated, are very low and changes in collective dose parameters are not expected to significantly affect the results. Again, the assessed per caput doses (up to 34.5 nSv y^{-1} for the UK due to Hinkley Point Site discharges) are well below the 20 µSv y^{-1} guideline that the Environment Agency suggests should require a more detailed assessment of uncertainty.

Regarding the potential build-up assessment, the doses are assessed using the methodology described in NRPB-W36. The main sources of uncertainty are on the types of scenarios considered. However, for those that are (future off-site construction worker and Fishing family using the sea) the habit data and discharge values considered are all conservative. Again, the assessed doses (up to 2.8 µSv y^{-1} for the adult in the Fishing Family) are well below the 20 µSv y^{-1} guideline that the Environment Agency suggests should require a more detailed assessment of uncertainty.

GLOSSARY & LIST OF PREFIXES

An explanation of the specific radiological protection terminology referred to within this report is provided below.

Term	Explanation
ALARP	As low as is Reasonably Practicable. The ALARP (As Low As Reasonable Practicable) principle is unique to British law. It requires the employer to provide systems (engineered, management etc.) to reduce the radiation dose until or unless the cost of implementing those measures (in time, trouble or money) is considered to be grossly disproportionate to the risk averted. In practice this requires the employer to go beyond the requirements of the ALARA principle in reducing dose.
ALARA	As low as is Reasonably Achievable. As Low as Reasonably Achievable (social and economic factors being taken into account). This term was introduced by the ICRP and requires that all be reasonably done to lower radiation exposures below Dose Limits. It requires the employer to provide systems to reduce the radiation dose until or unless the cost of implementing those measures (in time, trouble or money) is considered to be greater than the risk averted.
BPEO	Best Practical Environmental Option. This was defined by the 12th Report of the Royal Commission on Environmental Pollution as " the outcome of a systematic and consultative decision making process that establishes, for a given set of objectives, the option (e.g. for radioactive waste management) that provides the most benefit or least damage to the environment as a whole at acceptable cost in the long term and short-term as well.
BPM	Best Practical Means. A term used by the Environment Agencies requiring operators to take all reasonably practical measures in the design and management of their facilities to minimise discharges and disposals of radioactive waste so as to achieve a high standard of environmental protection of the environment and the public.
BAT	Best Available Technique. The Environment Agency has defined BAT (for the purposes of radioactive waste management) as the means by which an operator optimises the operation of a waste management practice to keep exposures from the disposal of radioactive waste ALARA, economic and social factors being taken into consideration. In their latest guidance, the Agency considers BPM and BAT to be essentially synonymous and to achieve the same overall outcomes
Build-up of radionuclides	The accumulation of radionuclides in environmental media, e.g. longer lived radionuclides such as Cs137 may accumulate in the soil as a result of continuous discharges over a prolonged period of time
Bq	Becquerel is the standard SI Unit of radioactivity. One Bq is defined as the activity of a quantity of radioactive material in which one nucleus decays per second. The Bq unit is therefore equivalent to s^{-1}.
C-14	An isotope of naturally occurring carbon (C-12) that is formed in small quantities in the natural environment and also be certain processes in a nuclear reactor. Its chemical properties are identical to those of carbon itself.
Collective dose	The collective dose is the summated individual exposures to a population group from a specified source within a specified time period. The unit of

Term	Explanation
	collective dose is joule per kilogram and has the usual name of man Sievert (Man Sv).
Critical rates	Habits (intakes and occupancies) that members of the critical group undergo. For example consumption at 97.5th percentile of national habit data.
Critical group	A group of members of the public which is reasonably homogeneous with respect to its exposure for a given radiation source and given exposure pathway and is typical of individuals receiving the highest effective dose or equivalent dose (as applicable) by the given exposure pathway from the given source.
Direct radiation	Ionising radiation emitted directly by processes or operations on premises and not as a result of discharges of radioactive substances to the environment. Mostly consisting of gamma photons that are attenuated to varying degrees by distance or structures such as walls and other barriers.
Environment Agency of England and Wales	An Executive Non-departmental Public Body responsible to the Secretary of State for Environment, Food and Rural Affairs and an Assembly Sponsored Public Body responsible to the National Assembly for Wales. Its stated aims are to protect and improve the environment, and to promote sustainable development. It was directly responsible for granting authorisations for the discharge of radioactive waste from nuclear premises under the requirements of RSA 93 and will continue to be responsible for permits under the more recent Environmental Permitting regime. Separate bodies carry out a similar role in Scotland and Northern Ireland.
EPR	European Pressurised Water Reactor. The EPR design is derived from the latest generations of reactors built in France (N4 Reactors) and Germany (KONVOI Reactors) and combines the safety experience and knowledge acquired from operating reactors. The proposed safety options also benefit from the results of research and development, in particular in the area of severe accidents.
EPR 2010	The Environmental Permitting Regulations, brought into force in 2010.
Fission products	Radioactive materials formed in nuclear fuel as a result of fission in a nuclear reactor and the production of heat and useful energy.
GDA	Generic Design Assessment. In this process, companies submit information on their reactor designs to the UK's Nuclear Regulators, who assess this information before a full application is made to build a nuclear power station at a particular site. The process involves a rigorous and structured examination of detailed design information by the Regulators. At the end of their assessment (and at key stages during it), the Regulators will issue reports on their findings, confirming whether they judge a design to be satisfactory.
HLW High level radioactive waste	High level waste is highly radioactive liquid waste that is produced when spent nuclear fuel is reprocessed. It is self heating and requires cooling. Over 95% of the radioactive material arising from the nuclear power industry is high level, but it has a very small volume. At Sellafield (British Nuclear Fuels Limited, Cumbria), liquid high level waste is solidified into a glasslike form (borosilicate) which reduces its volume even more.
IAEA	The International Atomic Energy Agency is the world´s center of co-operation in the nuclear field. Set up as the world´s "Atoms for Peace" organization in 1957 within the United Nations. The Agency works with Member States and multiple partners worldwide to promote safe, secure

Term	Explanation
	and peaceful nuclear technologies.
ICRP	International Commission on Radiological Protection. An independent Registered Charity, established to advance for the public benefit the science of radiological protection, in particular by providing recommendations and guidance on all aspects of protection against ionising radiation.
ILW Low Level Radioactive Waste	Intermediate Level Waste. Contains activity above the maximum specified limits for Low Level Waste but unlike High Level Radioactive waste, is not heat-generating. Most intermediate level waste is sufficiently radioactive to require shielding during its handling and transportation. It is currently stored at nuclear sites.
LLW Low Level Radioactive Waste	Solid waste materials containing radioactivity above the current Exemption value of 4 Bq g^{-1} beta gamma activity and a maximum of 12,000 bq g^{-1} beta gamma activity or 4,000 Bq g^{-1} alpha activity. Low level waste mostly consists of lightly contaminated materials and is disposed of by burial at approved sites, in the UK, principally at the Low Level Waste Repository near the village of Drigg in Cumbria.
m Sv	Milli -Sievert, 1/1000 th of the standard dose unit of a Sievert.
Most exposed members of the public	Synonymous to critical group but may be related to individual members of the public or a single source/pathway of exposure.
Nuclear Site	A site licensed by the Nuclear Installations Inspectorate under the Nuclear Installations Act 1965 and Nuclear Installations Regulations 1971.
Per Caput Dose	Collective dose averaged over all the individuals in the population over which the collective dose was estimated.
PID	Process and Information Document. A document drawn up by the Environment Agency requesting interested parties of new nuclear power station designs to provide information on a range of issues relating specifically to areas regulated by the agency (notably radioactive waste and discharges under RSA 93). Responses allow the Environment Agency to state, in principle, if a design is acceptable in the UK context. A separate, but similar, process is used by the Nuclear safety Directorate of the HSE to address issues under their regulatory control (Site License Conditions). Satisfactory responses to the process are not binding on the Agency and a separate process will be required for obtaining an authorisation to discharge radioactive waste under RSA 93 from any specific future site.
PCER	Pre-construction Environmental Report. Report produced by EDF (or other prospective site operators or plant designers) to satisfy the requirements of the PID. Forms part of the GDA (Generic Design Assessment) submissions.
Radioactive waste	Legal definitions of radioactive material and radioactive wastes are contained in Sections 1 and 2 of the Radioactive Substances Act 1993; the effect of the definitions is that radioactive waste generally includes: a) scrap, surplus or spoilt radioactive material; and b) any other waste substance or article which has become radioactive or has acquired an increased concentration of radioactivity.
Ramsar	The Convention on Wetlands (Ramsar, Iran, 1971) - called the "Ramsar Convention" -- is an intergovernmental treaty that embodies the commitments of its member countries to maintain the ecological

Term	Explanation
	character of their Wetlands of International Importance and to plan for the "wise use", or sustainable use, of all of the wetlands in their territories. Unlike the other global environmental conventions, Ramsar is not affiliated with the United Nations system of Multilateral Environmental Agreements (MEA), but it works very closely with the other MEAs and is a full partner among the "biodiversity-related cluster" of treaties and agreements.
Short-term dose	Dose incurred due to short-term releases of a significant proportion of the 12-month discharge limit, can occur as a result of variations in site operations. For assessment purposes the duration of a release is typically assumed to be 30 minutes or 24 hours.
Spent fuel	Fuel that is removed from the reactor due to operational constraints such as having met its designed burn-up (energy production). It contains the majority of the radioactive materials formed in the reactor. After it is removed from the reactor it is stored underwater on-site to cool until a final off site route is decided on (notably reprocessing or direct disposal).
SSSI	Site of Special Scientific Interest is a conservation designation denoting a protected area in the United Kingdom.
Tritium	A radioactive isotope of hydrogen formed in a nuclear reactor via a range of processes. Most appears as tritiated water that has predominantly the same physical and chemical properties of water so behaves in the same way in the environment.
Gray (Gy)	The Gray is a unit used to measure a quantity called absorbed dose. This relates to the amount of energy actually absorbed in some material, and is used for any type of radiation and any material. One Gray is equal to one joule of energy deposited in one kg of a material. The unit Gray can be used for any type of radiation, but it does not describe the biological effects of the different radiations. As there are no dose coefficients for non human species due to a lack of biological data, doses are expressed in Gray.
Sievert (Sv)	The Sievert is a unit used to derive equivalent dose. This relates the absorbed dose in human tissue to the effective biological damage of the radiation. To determine equivalent dose (Sv), you multiply absorbed dose (Gy) by a quality factor (Q) that is unique to the type of incident radiation. Doses to humans are expressed in Sieverts as biological data is readily available for humans.

APPENDIX B

Human assessment input parameters

Table B1: Fishing Family who also consume terrestrial foodstuffs habit parameters based on CEFAS[53] data

Parameter	Adult	Child	Infant
Occupancy home outdoors ($h\ y^{-1}$)	2420[s]	1577	866
Occupancy home indoors ($h\ y^{-1}$)	4,380	7,008	7,884
Fraction of time indoors	0.5	0.8	0.9
Occupancy on beach (hy^{-1})	1960	175	10[t]
Breathing rate marine ($m^3\ h^{-1}$)	1.69	1.12	0.35
Breathing rate terrestrial ($m^3\ h^{-1}$)	0.92[u]	0.64	0.22
Handling fishing gear (hy^{-1})	1,560	0	0
Ingestion of sea fish (kg $person^{-1}y^{-1}$)	47.2	11.8	2.6[v]
Ingestion of crustacea (kg $person^{-1}y^{-1}$)	15.3	1.5	0
Ingestion of mollusca (kg $person^{-1}y^{-1}$)	1.9	0	0
Fraction of seafood caught locally	1	1	1
Marine area of interest	Bristol Channel		
Ingestion of locally produced green vegetables. (kg $person^{-1}y^{-1}$)	33.4	23.3	4.8
Ingestion of locally produced root vegetables. (kg $person^{-1}y^{-1}$)	49.1	26.6	12.3
Ingestion of locally produced fruit (kg $person^{-1}y^{-1}$)	16.2	6.6	7.5
Ingestion of locally produced sheep meat (kg $person^{-1}y^{-1}$)	7.7	3.1	0.9
Ingestion of locally produced cow meat (kg $person^{-1}y^{-1}$)	26.9	14.3	6.0
Ingestion of locally produced milk (kg $person^{-1}y^{-1}$)	136.6	158.1	186.9
Ingestion of locally produced milk products (kg $person^{-1}y^{-1}$)	31.7	23.8	23.8

[s] Calculated based on 50% indoor occupancy and 1960 hours per year on the beach
[t] As there is only 1 infant observation it should be noted that using the term '97.5th percentile' is not strictly correct in this case
[u] As a fisherman during terrestrial occupancy hours this individual is not working and hence a worker breathing rate is not appropriate
[v] As there is only 1 infant observation it should be noted that using the term '97.5th percentile' is not strictly correct in this case

Table B2: Farming Family who also consume locally caught seafoods. Habit parameters based on CEFAS[53] data.

Parameter	Adult	Child	Infant
Occupancy in the local area($h\ y^{-1}$)	8,760	8,760	8,760
Recreational beach occupancy ($h\ y^{-1}$)	400	175	10
Fraction of time indoors	0.5	0.8	0.9
Breathing rate terrestrial ($m^3\ h^{-1}$)	1.12	0.64	0.22
Distance to Farm[w]	1.65 km		
Bearing to Farm[jj]	134º		
Ingestion of locally produced green vegetables. (kg $person^{-1}y^{-1}$)	33.4	23.3	4.8
Ingestion of locally produced root vegetables. (kg $person^{-1}y^{-1}$) (97.5th rate for adult, average rates for child and infant)	121.5	26.6	12.3
Ingestion of locally produced fruit (kg $person^{-1}y^{-1}$)	16.2	6.6	7.5
Ingestion of locally produced sheep meat (kg $person^{-1}y^{-1}$)	7.7	3.1	0.9
Ingestion of locally produced cow meat (kg $person^{-1}y^{-1}$)	26.9	14.3[x]	6.0
Ingestion of locally produced milk products (kg $person^{-1}y^{-1}$) (97.5th rate for child and infant and average for adult)	36.3	27.2	27.2
Ingestion of milk (kg $person^{-1}y^{-1}$)	136.6	207.40	276.5
Ingestion of sea fish (kg $person^{-1}y^{-1}$)	13.4	11.2	2.6
Ingestion of crustacea (kg $person^{-1}y^{-1}$)	2.6	1.5	0
Ingestion of mollusca (kg $person^{-1}y^{-1}$)	1.9	0	0

[w] From EPR East (C1) stack
[x] As there is only 1 child observation who consumes cow meat, the terms 'mean' and '97.5th percentile' are not strictly correct in this case. However, this data is consistent with the NRPB W41 value.

APPENDIX C

Collective dose parameters

Table C1: Summary of collective dose parameters

Parameter	Value
Collective dose truncated at year	500
Populations of interest	UK, Europe, World
Effective Release Height HPC (m)	23.3
Effective Release Height HPA (m)	17.8
Effective Release Height HPB (m)	21
Meteorological data	Hinkley Point centred Meteorological data for the period 1999-2008
Regional marine compartment	Bristol Channel

APPENDIX D

Short-term input parameters

Table D1: Activity discharged in a short-term release (24 hour discharge scenario)

		24 hour discharge scenario
Radionuclide	Total activity discharged (Bq)	Discharge rate (Bq s^{-1})
H-3	$3.00\ 10^{11}$	$3.47\ 10^{6}$
C-14	$1.00\ 10^{11}$	$1.16\ 10^{6}$
Kr-85	$6.95\ 10^{11}$	$8.04\ 10^{6}$
Xe-133	$3.16\ 10^{12}$	$3.66\ 10^{7}$
Xe-135	$9.90\ 10^{11}$	$1.15\ 10^{7}$
Ar-41	$1.45\ 10^{11}$	$1.68\ 10^{6}$
Xe-131m	$1.50\ 10^{10}$	$1.74\ 10^{5}$
I-131	$1.37\ 10^{8}$	$1.59\ 10^{3}$
I-133	$1.63\ 10^{8}$	$1.89\ 10^{3}$
Co-58	$1.53\ 10^{7}$	$1.77\ 10^{2}$
Co-60	$1.81\ 10^{7}$	$2.09\ 10^{2}$
Cs-134	$1.40\ 10^{7}$	$1.62\ 10^{2}$
Cs-137	$1.26\ 10^{7}$	$1.46\ 10^{2}$

Table D2: Short-term habit and site parameters

Parameter	Value
Date of release	1st July[y]
Time of day of release	00:00 to 24:00
Discharge period (h)	24
Stack Height (m)	70
Effective Stack Height (m)	23.3
Receptor point (m)	Locality subject to maximum dose from atmospheric discharges from HPC
Distance between EPR reactor centres	230 m
Met Data	Hinkley Point specific
Reduction factor, inhalation – indoors occupancy[z]	0.5
Location factor cloud gamma – indoors occupancy	0.2
Location factor deposited gamma – indoors occupancy	0.1
Location factor deposited gamma – outdoors occupancy	1
Fraction of food locally produced	1
Occupancy terrestrial adult (h y^{-1})	8,760
Occupancy terrestrial child (h y^{-1})	8,760
Occupancy terrestrial infant (h y^{-1})	8,760
Fraction of time indoors terrestrial adult – outdoor worker	0.5
Fraction of time indoors terrestrial child – 5-10 y old	0.8
Fraction of time indoors terrestrial infant	0.9
Breathing rate terrestrial adult m^3 h^{-1} – indoors	0.48
Breathing rate terrestrial child m^3 h^{-1} – indoors	0.58
Breathing rate terrestrial infant m^3 h^{-1} – indoors	0.21
Breathing rate terrestrial adult m^3 h^{-1} – outdoors	1.75
Breathing rate terrestrial child m^3 h^{-1} – outdoors	0.87
Breathing rate terrestrial infant m^3 h^{-1} – outdoors	0.31
Ingestion rates See Appendix B– Table B 2, Terrestrial Ingestion rates only	
Ingestion rates	See Appendix B – Table B2, Terrestrial Ingestion rates only

[y] Assumed for calculation purposes that release occurs on 1st July, however met. data for June to August for the years 1999 to 2008 has been used to determine 97.5th percentile values rather than met data specific to 1st July.

[z] Reduction factor only relevant for depositing radionuclides, i.e., Co, Cs, I. There is no reduction factor for non-depositing radionuclides.

APPENDIX E

Build-up parameters

Table E1: Site and PC CREAM parameters for build-up assessment

Parameter	Recommended value
Activity Concentration calculated at year	60
Effective Release Height HPC (m)	23.3
Effective Release Height HPA (m)	17.8
Effective Release Height HPB (m)	21
Met data	Hinkley Point Specific

Table E2: Parameters for construction workers scenario

Parameter	Value
Age group	Adult
Working year (hours)	2000
Is respiratory protection worn?	None
Time spent on site (hours)	2000
Fraction of time spent outside	1
Fraction of time spent outside with disturbed ground	0.1
Time spent manually digging (hours)	20
Time spent mechanically digging (hours)	180
INH_h (m^3h^{-1})	3
INH_{am} (m^3h^{-1})	1.5
Fraction of the area occupied that is assumed to be contaminated	1.0
Distance and Bearing from EPR East (C1)	427m, 105 degrees

Table E3: Dose to construction worker from work on land contaminated by HPC gaseous discharges

Radionuclide	External Dose (Sv y^{-1})	Skin Dose (Sv y^{-1})	Inhalation Dose (Sv y^{-1})	Ingestion Dose (Sv y^{-1})	Total dose (Sv y^{-1})
Co-58	$3.67\ 10^{-11}$	$1.06\ 10^{-15}$	$3.74\ 10^{-16}$	$3.26\ 10^{-16}$	$3.67\ 10^{-11}$
Co 60	$2.52\ 10^{-09}$	$1.13\ 10^{-13}$	$4.96\ 10^{-14}$	$3.91\ 10^{-14}$	$2.52\ 10^{-09}$
Cs 134	$3.17\ 10^{-10}$	$3.64\ 10^{-14}$	$2.22\ 10^{-14}$	$7.22\ 10^{-14}$	$3.17\ 10^{-10}$
Cs 137	$1.39\ 10^{-09}$	$3.80\ 10^{-13}$	$1.20\ 10^{-13}$	$3.84\ 10^{-13}$	$1.40\ 10^{-09}$
I 131	$9.06\ 10^{-11}$	$2.91\ 10^{-14}$	$1.60\ 10^{-14}$	$5.28\ 10^{-14}$	$9.07\ 10^{-11}$
I 133	$1.19\ 10^{-11}$	$4.20\ 10^{-15}$	$4.02\ 10^{-16}$	$1.35\ 10^{-15}$	$1.19\ 10^{-11}$
Total	$4.37\ 10^{-09}$	$5.63\ 10^{-13}$	$2.09\ 10^{-13}$	$5.49\ 10^{-13}$	$4.37\ 10^{-09}$

Table E4: Dose to construction worker from work on land contaminated by cumulative Hinkley site gaseous discharges

Radionuclide	External Dose ($Sv\ y^{-1}$)	Skin Dose ($Sv\ y^{-1}$)	Inhalation Dose ($Sv\ y^{-1}$)	Ingestion ($Sv\ y^{-1}$)	Total ($Sv\ y^{-1}$)
Co-58	$3.67\ 10^{-11}$	$1.06\ 10^{-15}$	$3.74\ 10^{-16}$	$3.26\ 10^{-16}$	$3.67\ 10^{-11}$
Co 60	$1.64\ 10^{-08}$	$7.35\ 10^{-13}$	$3.23\ 10^{-13}$	$2.55\ 10^{-13}$	$1.64\ 10^{-08}$
Cs 134	$3.17\ 10^{-10}$	$3.64\ 10^{-14}$	$2.22\ 10^{-14}$	$7.22\ 10^{-14}$	$3.17\ 10^{-10}$
Cs 137	$1.39\ 10^{-09}$	$3.80\ 10^{-13}$	$1.20\ 10^{-13}$	$3.84\ 10^{-13}$	$1.40\ 10^{-09}$
I 131	$2.08\ 10^{-10}$	$6.66\ 10^{-14}$	$3.68\ 10^{-14}$	$1.21\ 10^{-13}$	$2.08\ 10^{-10}$
I 133	$1.19\ 10^{-11}$	$4.20\ 10^{-15}$	$4.02\ 10^{-16}$	$1.35\ 10^{-15}$	$1.19\ 10^{-11}$
S-35	$0.00\ 10^{+00}$	$5.51\ 10^{-12}$	$6.68\ 10^{-13}$	$7.70\ 10^{-13}$	$5.95\ 10^{-12}$
Total	$1.84\ 10^{-08}$	$5.73\ 10^{-12}$	$1.16\ 10^{-12}$	$1.60\ 10^{-12}$	$1.84\ 10^{-08}$

APPENDIX F

Non-Human parameters and results

Table F1: Animal species recorded in Hinkley Point area and ERICA reference

Animal	ERICA reference
Bats	
Pipistrelle	User Defined
Myotis	User Defined
Rhinolophus hipposideros	User Defined
Nyctalus noctula	User Defined
Eptesicus serotinus	User Defined
Plecotus auritus	User Defined
Mammals	
Water Vole	Freshwater mammal
Deer	Mammal (deer)
Badger	User Defined
Reptiles	
Slow Worm	Reptile
Grass Snake	Reptile
Insects	
Great Silver Water Beetle	
Water beetle	
Hoverfly	Flying Insect
Soldier flies1	Flying Insect
Aquatic snail	Gastropod
Hairy dragonfly	Flying Insect
Ladybird	Flying Insect
Birds	
Whimbrel	Bird
Black Tailed Godwit	Bird
Wigeon	Bird
Dunlin	Bird
Nightingale	Bird
Peregrine falcon	Bird
Jackdaw	Bird
Stonechat	Bird
Kestrel	Bird
Collared and Stock doves	Bird
Whitethroat	Bird
Rock Pipit	Bird

Animal	ERICA reference
Linnet	Bird
Dunnock	Bird
Other	
Salt Marsh Grazed Sheep	Mammal (deer)
Bee	Flying insect
Trout	Pelagic Fish
Farm	
Cow	Mammal (deer)
Sheep	Mammal (deer)
Pig	Mammal (deer)
Chicken	Bird
Marine	
Grey mullet	Benthic fish
Plaice	Benthic fish
Dogfish	Benthic fish
Cuttlefish	Mollusc
Skate	Benthic fish
Prawns	Crustacean
Sea Bass	Benthic fish
Sole	Benthic fish
Crustacean	Crustacean
Mollusc	Mollusc
Wild Fowl	Bird
Butterflies	
Chalkhill blue	Flying Insect
Dark green fritillary	Flying Insect
Meadow brown	Flying Insect
Marbled white	Flying Insect
Small heath	Flying Insect
Common blue	Flying Insect

Table F2: Plant species recorded in Hinkley Point area and ERICA reference

Plants	ERICA reference
Hedgerow	
Ash	Tree
Blackthorn	Tree
Brambles	Tree
Dog Rose	Shrub
Dogwood	Shrub
Elder	Tree
Elm	Tree
Field Maple	Tree
Hawthorn	Shrub
Ivy	Tree
Privet	Shrub
Wayfaring Tree	Tree
Spindle	Shrub
Other	
Oilseed rape	Grasses & Herbs
Hay meadow	Grasses & Herbs
Deciduous woodland	Tree
Tussocky grassland	Grasses & Herbs
Marine plants and algae	Macroalgae/vascular plants
Seaweed	Macroalgae

APPENDIX G

Transport parameters and results

Table G1: Waste packages to be consigned annually from Hinkley Point UK EPRs

Type of waste	Package description	Packages per year	Typical activity (MBq/package unless otherwise stated)[aa]
SGBS ion-exchange resins (without regeneration)	0.2 m^3 plastic drums	76	11.84
Wet sludge (sumps, tanks)	0.2 m^3 metallic drums	16	900
Water filters from effluent treatment	0.2 m^3 metallic drums	2	180
Non compactable: air and water filters	0.2 m3 metallic drums	40	50
Pre-compacted operational wastes (plastics, clothes, small items)	0.2 m^3 metallic drums	126	248 (per m^3)
	0.2 m^3 plastic drums	376	248 (per m^3)
Scraps	1 m^3 metallic boxes	12	2333
Operational waste	0.2 m^3 metallic drums	2	480
Total LLW	-	650	-
Spent fuel	Fuel Flask	100	$1.5\ 10^{10}$ (bb)

[aa] Typical activities are for information only. The dose values for the transport scenarios are based on generic NRPB dose rates given in Table G2 (over).
[bb] Activity taken from NRPB-W66, Table 14 “other UK and overseas sites to the reprocessing site”.

Table G2: Annual radioactive material consignments for Hinkley Point EPR

Packages	Contents	Activity per conveyance GBq	Typical contact dose rate µSv h^{-1}[cc]	Typical dose rate at 1m µSv h^{-1}
Type A/B source containers	NDT radiography sources	<1 10^3	-	2
New fuel casks	New fuel assemblies	Unknown [dd]	Unknown	4
186 x 0.2 m^3 metallic drums in 2 ISO containers	Wet sludge (sumps, tanks), Water filters from effluent treatment, Non compactable: air and water filters, Operational waste, Pre-compacted operational wastes (plastics, clothes, small items…)	24.5	15	6
452 x 0.2 m^3 plastic drums in 5 ISO containers	SGBS ion-exchange resins (without regeneration), Pre-compacted operational wastes (plastics, clothes, small items)	18.8	15	6
12 x 1m^3 metallic boxes	Scraps	2.3	15	6
100 Fuel Flasks	Spent fuel	1.5 10^7	20	2

[cc] Contact dose rates taken from Table 18 of NRPB-W66. The one PWR in the UK does not transport flasks of spent fuel. Therefore general maximum values have been used.
[dd] The activity per conveyance will depend on the enrichment and type of fuel – not known at this stage.

Table G3: Scenarios considered

Source	Bus stop	College	House at 5m	House at railhead
NDT sources	Yes	Yes	Yes	No
New fuel	Yes	Yes	Yes	No
LLW	Yes	Yes	Yes	No
Spent Fuel	Yes	Yes	Yes	Yes

Table G4: Annual dose to critical members of public.

Scenario	Content of package	Distance between vehicle and member of public (m)	Exposure time per movement (min)	Exposure time per movement (h)	Dose rate at 1m ($\mu Sv\ h^{-1}$)	Annual number of movements exposed to.	Dose rate at receptor ($\mu Sv\ h^{-1}$)	Annual Dose (μSv)
Bus stop	NDT sources	1	1	0.017	2	10	2.00	0.51[ee]
	New fuel	1	1	0.017	4	5	4.00	0.33
	LLW	1	1	0.017	6	5	6.00	0.50
	Spent fuel	1	1	0.017	2	13	2.00	0.43
College	NDT sources	15	1	0.017	2	31	0.01	0.0075[ee]
	New fuel	15	1	0.017	4	125	0.02	0.04
	LLW	15	1	0.017	6	15	0.03	0.01
	Spent fuel	15	1	0.017	2	80	0.01	0.01
Railhead	Spent fuel	20	240	4	2	100	0.005	2.00
House	NDT sources	5	1	0.017	2	40	0.08	0.08[ee]
	New fuel	5	1	0.017	4	125	0.80	1.67
	LLW	5	1	0.017	6	19	1.20	0.38
	Spent fuel	5	1	0.017	2	100	0.40	0.67

[ee] Includes a factor of 1.5 to account for return factor of spent NDT sources

APPENDIX 22A: ZTV METHODOLOGY

Appendix 22.A

Zone of Theoretical Visibility - Methodology

Introduction

A Zone of Theoretical Visual (ZTV) is used in the Landscape and Visual Impact Assessment (LVIA) process to illustrate the areas of surrounding landscape from which proposed features would be theoretically visible.

ZTV is typically a 'bare ground' scenario based on topographical analysis and it does not take account of other screening factors, such as vegetation or buildings. It is therefore considered to be a 'worst case scenario' in terms of the potential visibility of the proposed features.

ZTV is a key supporting tool used in visual analysis and allows identification of areas from which proposed features would not be seen with high certainty and accuracy. It is typically overlaid onto an OS map and represented by colours showing different levels of visibility. The areas identified as having potential for visibility of the proposed features are then reassessed during site visits to establish the actual visibility of the proposed features by taking account of all screening features, including vegetation or buildings.

Software and data

All ZTVs for the Hinkley Point C (HPC) project have been prepared using Key Terra Firma (KTF) Release 7 module for AutoCAD 2008. The following datasets were used during the preparation of ZTV for the proposed development within the HPC development site:

- Ordnance Survey (OS) 1:50,000 Scale Colour Raster map. Mapping extents: 291624, 171668 (top left corner OS grid reference); 340575, 123019 (bottom right corner OS grid reference). The 1:50,000 Scale Colour Raster provides a digital view of Ordnance Survey's Landranger® map series and has a wide variety of uses across all areas of business. The maps detail roads, footpaths, woods, water features, important buildings and contour lines.
- OS Landform Profile Digital Terrain Model (DTM) ASCII XYZ height data. This dataset does not cover part of the Bridgwater Bay to the north-west of the proposed HPC development site. Mapping extents: 291624, 171668 (top left corner OS grid reference); 340575, 123019 (bottom right corner OS grid reference). In this Digital Elevation Model (DEM) the ground surface has been modelled in detail with elevation points provided every five meters. This dataset is considered sufficient for carrying out analysis of large study areas. In the Landform Profile DTM, the whole country has been covered using airborne RADAR technology that provides a one-meter vertical resolution for the first reflective surface that is subsequently interpolated using a bespoke "TerrainFit" algorithm to derive the underlying 'bare ground' or terrain model.

ZTV Analysis

Ground model

The initial requirement before starting a ZTV analysis is to create a model using the suitable height data for the LVIA study area. The model for HPC development site has been created from the OS Landform Profile DTM ASCII .xyz file using the Gridding method.

KTF ground model settings:

- Extents: X: 291630, 340570; Y: 123020, 171660
- Area: 50km x 50km
- Triangles in model: 100350 (all active)

Running ZTV analysis

ZTV analysis is carried out by drawing a series of rays radiating out from the target points (proposed features) and it may help to consider this as many hundreds or thousands of sections being calculated automatically (see Plate 1). Each section is then divided into 'visible' and 'invisible' sub-sections, which indicate whether the proposed features are visible or not (see Plate 2).

The ZTV Analysis was carried out on 22 February 20010. To reflect the visibility of the proposed HPC proposed development in the surrounding landscape it was considered appropriate to use the following target points for the ZTV analysis:

- 2 target points at the elevation of +84m Above Ordnance Datum (AOD). These target points were placed on top of the tallest proposed structures (stacks).
- 76 target points located 10m above the existing ground level within the HPC development site (to allow for the proposed topographical changes within the HPC development site outside the HPC permanent development area).
- The visibility of the stacks (the tallest proposed structures) is a good indicator of the potential maximum visibility of the HPC proposed development, additional points at the ground level were added to reflect the visibility of the southern part of the HPC development site, in particular in the short and medium distance, where stacks might be screened by the existing landform but the southern parts of the HPC proposed development site might be visible. In the long distance, the lack of visibility of the stacks means that the lower levels of the HPC proposed development site would not be visible.

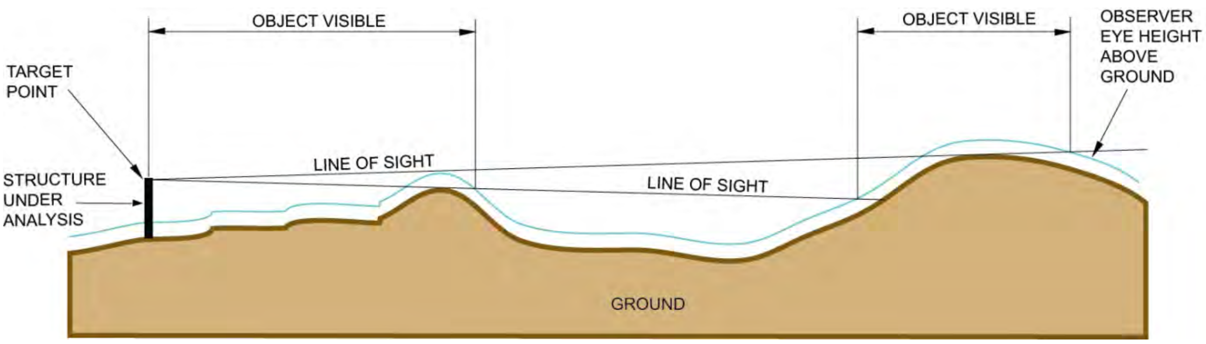

Plate 1 Illustration of ZTV analysis. Based on: KTF Ltd. (2007) ZVI and Visualisation

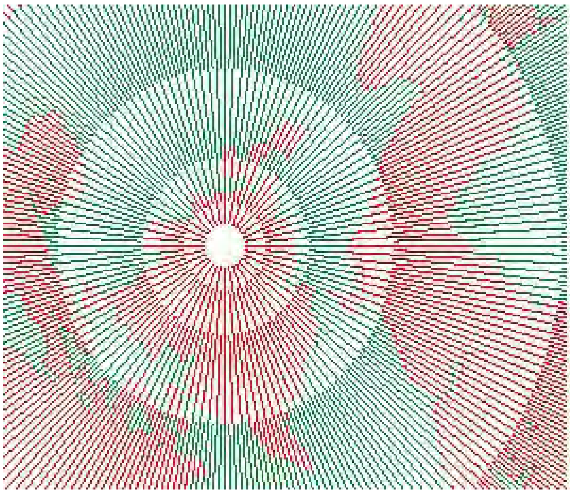

Plate 2 Example of single point analysis showing 'visible' (red) and 'invisible' (green) rays (source: KTF Ltd. (2007) ZVI and Visualisation)

ZTV analysis settings:

- Area: 50km x 50km (extents of the KTF ground model);
- Elevation of 2 target points at the top of the stacks: +84m AOD;
- Number of remaining target points within the HPC development site: 76 (elevation varies and set 10m above the existing ground levels);
- Ray resolution: 100m;
- Optimal Density Expansion (ODE) Expansion method: Yes. This was set 'on' to ensure that the lateral spacing between adjacent rays will never exceed the ray resolution value (see Plate 3);
- Start distance: 100m from each target point;
- Visual barriers: no.

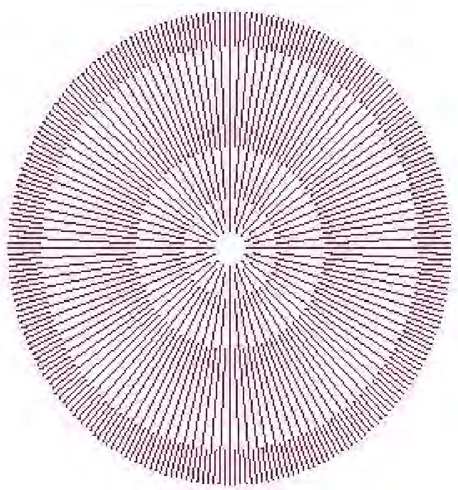

Plate 3 Example of rays for a single target analysis using ODE Expansion method (source: KTF Ltd. (2007) ZVI and Visualisation)

Colour mapping – graphical output

The ZTV analysis output file was saved as a Visibility Model, which is typically used for multiple target point analysis. It allows mapping areas using user defined colours assigned to a number of potentially visible targets.

For the purpose of HPC proposed development ZTV analysis, one colour band was chosen (blue) for mapping all areas from which at least one target point would be visible.

The graphical output was then overlaid onto OS 1:50,000 Scale Colour Raster map using OS grid references.

1 Hayes Davidson

1.0 Hayes Davidson (London) LLP was founded in 1989 to specialise in computer aided architectural illustration. The company has a team which deals exclusively in the creation of three dimensional digital models and the representation of buildings and cities. The team is overseen by four managing Partners all of whom have architectural, technical and artistic experience. A Partner specialising in Technical and Planning disciplines with qualifications and experience of geometry and construction oversees all projects where geometric definition and accuracy is required. Hayes Davidson has been invited to sit on judging panels for a number of architectural illustration awards, and lecture on computer aided illustration techniques, perception and three dimensional representation.

1.1 Alan Davidson, the founder and Managing Director, has a BA and MA (Hons.) in Architecture from the University of Edinburgh and is an ARCUK registered architect. He studied Fine Art and attended Art College in Edinburgh. He has worked as an architect since 1986 and an architectural illustrator since 1979.

1.2 Hayes Davidson is considered to be the most experienced architectural computer imaging company working in the UK having produced over 10,000 'virtual' or 'computer aided' images since 1989. The work of Hayes Davidson has been acknowledged as pioneering; advancing the use of computer technologies in the representation of buildings. The work has been widely published. Hayes Davidson has won the CICA ('Construction Industry Computing Association') award for the best computer rendering of buildings three years consecutively. The computer generated artwork of Hayes Davidson is collected by the Royal Institute of British Architects Drawings Collection.

1.3 The following is a reference for Hayes Davidson from Dr. Neil Bingham, Assistant Curator of the Royal Institute of British Architects Drawings Collection.

"The RIBA Drawings Collection was established at the foundation of the RIBA in 1834, now holds an estimated 3/4 million drawings, and is considered one of the finest architectural collections in the world. Since 1994, the RIBA has been acquiring the work of Hayes Davidson. The Drawings Collection recognise their work as representing some of the highest quality and most important architectural illustration of the late 20th Century."

1.4 Hayes Davidson is the only company to our knowledge to have verified photomontage, videomontage and surround montage accepted at public inquiry level in the UK. Hayes Davidson has produced evidence for both the Heron Tower (Architect Kohn Pedersen Fox) and London Bridge Tower (Architect Renzo Piano Building Workshop) Inquiries. On both occasions the material produced by Hayes Davidson has been accepted and praised by the Inquiry.

2 Work Commissioned

2.0 Hayes Davidson was commissioned by EDF Energy to produce a series of dimensionally accurate Visually Verifiable Images in a rendered format of the proposed EDF Energy Hinkley Point C development from 42 viewing locations at positions varying from 25m to 20km from the site. All views were to be represented in daylight conditions with 13 views also being represented at dusk.

2.1 Each of these views of the proposal was to be created as Visually Verifiable Images (VVI's). A Visually Verifiable Image (VVI) is an image of a proposed element in its future context, prepared using a repeatable, verifiable methodology.

2.2 Preparation of VVI is complex and challenging and the choice of simulation and technique is essential. This is described in section 3.

2.3 In order to prepare VVI, it is necessary to establish the view positions accurately at the source. The view positions were agreed by EDF Energy with statutory and local consultees and this information was provided to Hayes Davidson by Gillespies Landscape Architects. The viewing positions are described in section 4 and Appendix A and B.

2.4 High resolution photography suitable for use in the preparation of VVI was required for all views. The specification and process for capturing the photography is described in section 5.

2.5 Accurately surveyed camera positions and local context are an essential part of the verifiable view creation process. A chartered survey company was employed to carry out this precision work and this is described in detail in section 6.

2.6 Photography captured at site requires colour correction and preparation in order to be suitable for use as a baseline for the AVR image. This is described in section 7.

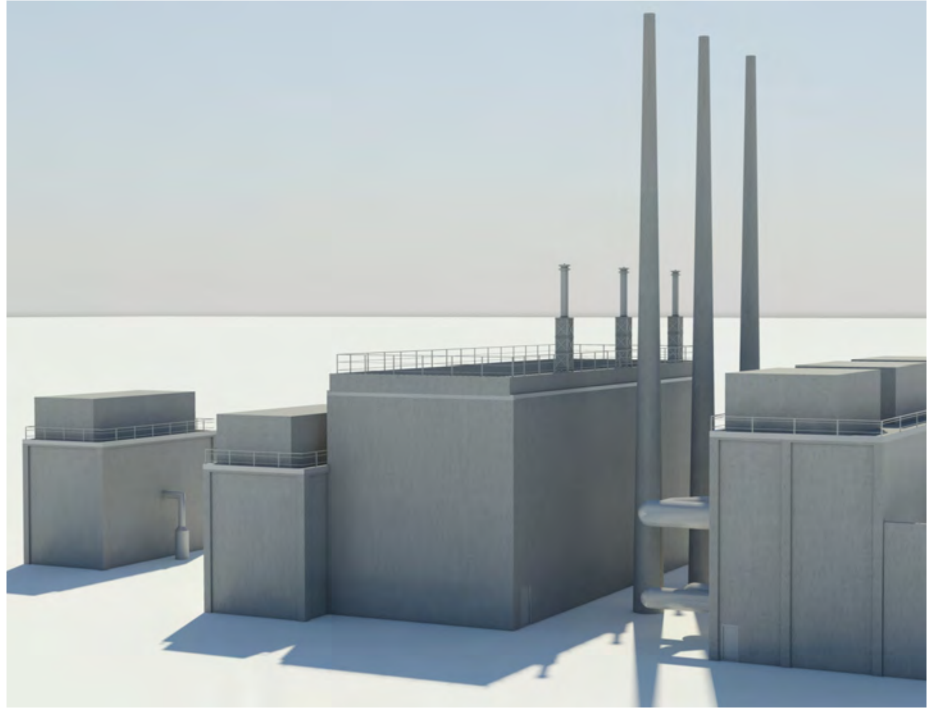
2.7 Accurate digital 3D models of the proposed development were created by Hayes Davidson for use in the VVI images. All drawn and digital information regarding the proposed development was supplied to Hayes Davidson in digital and hardcopy format by YRM Architects and Gillespies Landscape Architects. Section 8 describes the 3D modeling and location process. The building locations are in Appendix C.

2.8 Once the site based information, photography post-processing and 3D modeling is complete it is necessary to align these components accurately. This is described in section 9.

2.9 When an accurate alignment is achieved and confirmed through the studio QA process, final image production can occur. This is described in section 10.

2.10 The VVI images are designed to be viewed in print at a predetermined viewing distance. The way we calculate this viewing distance and how we determine the field of view is described in Section 11 and Appendix D.

On-site photography



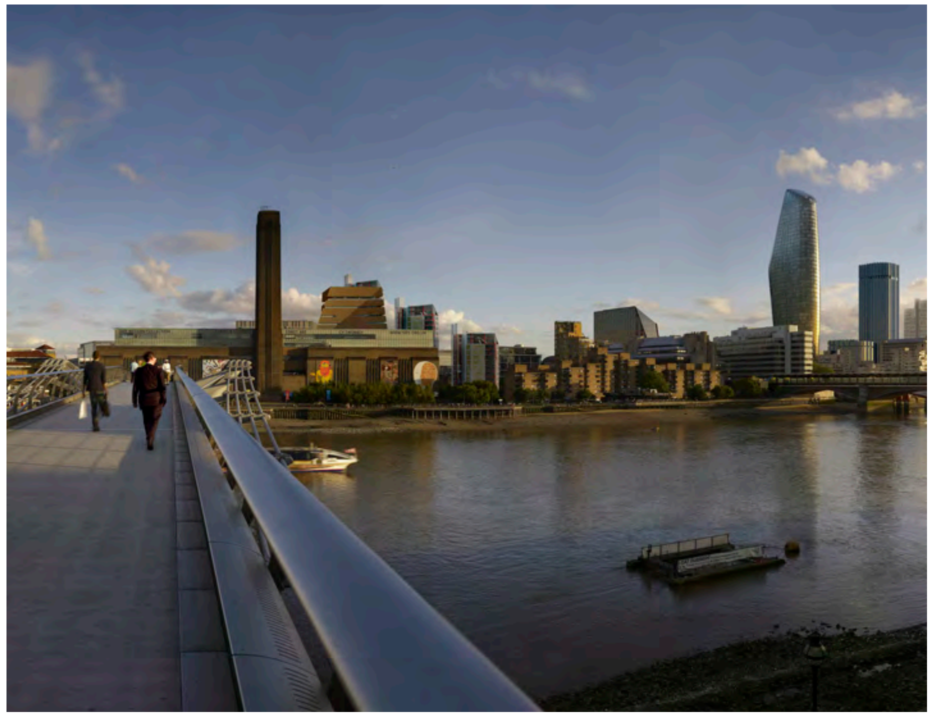
Modelling of structures - early development

Accurate viewpoint location

Terrain modelling

3 Choice of simulation technique

Depth



Silhouette

Night Lighting

Surrounding context

3.0 It is important to emphasise that no media can currently reproduce the human experience of viewing a scene. There is no method of analysis or representation that will accurately summarise every lighting, material, social, sensory or climatic condition.

3.1 A photomontage is the superimposition of an image onto a photograph for the purpose of creating a realistic representation of proposed or potential changes to a view. Printed photomontage allows the highest resolution and allows the eye to see the greatest detail. In this way it starts to simulate the effect of looking at a view from a single position.

3.2 Setting aside time of day and year and local climactic conditions, the different aspects of a building that contribute to its aesthetic appearance can be summarised as follows: (For the purpose of simplicity we will disregard the speed of walking and social and other sensory influences but these are also relevant).

- proportion (height, width)
- distance / depth from viewer
- outline and definition of building edges
- the viewers 360º awareness of the surroundings
- position in view
- the effect of light on and the nature of the buildings materials
- night lighting
- nature of surrounding buildings/ structures (shadowing and reflection)

3.3 The images presented have been created using a verifiable methodology that will allow a third party to verify the accuracy of the scale, height and mass of the proposal. Not all simulation techniques can be verified and where detailed analysis of materials and their behaviour to light are to be considered, no wholly objective analysis method is possible, and the architect and Hayes Davidson work together to apply subjective judgement. The shading presented is based on the position of the sun at the date and time of the capture of the baseline photography.

4 Viewpoint establishment

4.0 The list of viewpoints was agreed by EDF Energy with statutory and local consultees. The approximate location and photo references for each of the view positions were provided to Hayes Davidson by Gillespies Landscape Architects.

4.1 Hayes Davidson, a professional architectural photographer and members of a chartered surveying team attended the site in February 2011 to establish the view positions.

4.2 Each of the attendees was fully inducted in site safety and security processes and requirements at the existing Hinkley Point B site prior to the commencement of any viewpoint establishment.

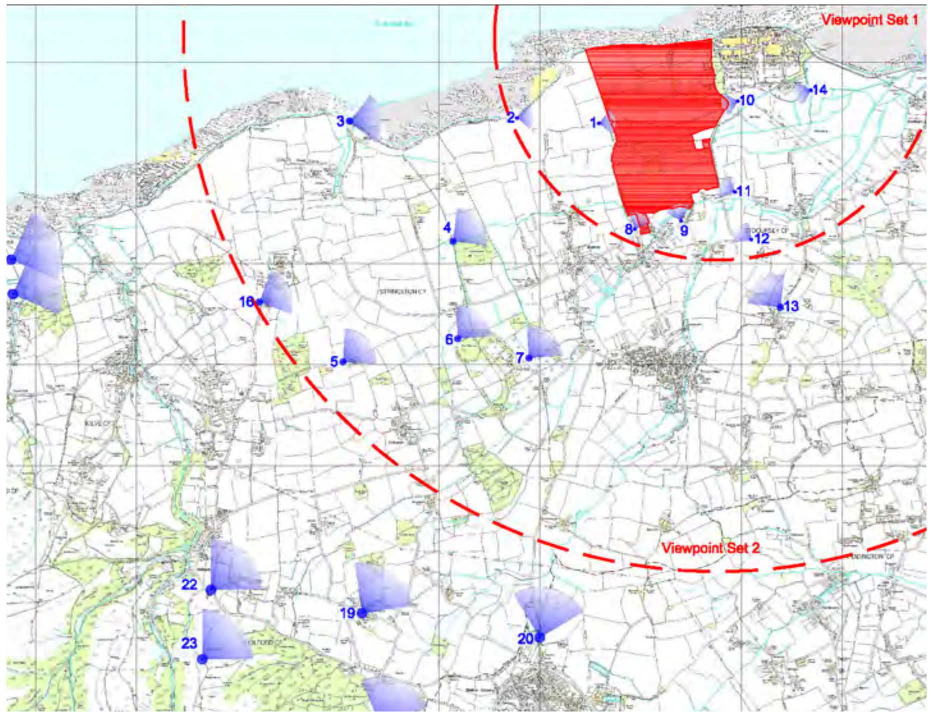
4.3 Using the information provided by Gillespies Landscape Architects, the team visited each viewpoint. Where necessary, relevant permissions to access private land were obtained through EDF Energy.

4.4 At each view position the location was matched using the provided Gillespies information. Where a composition needed to be improved due to obstruction or foliage growth, a more suitable position was chosen that still demonstrated the requirement of the original view. In each case the variations to each position was marginal.

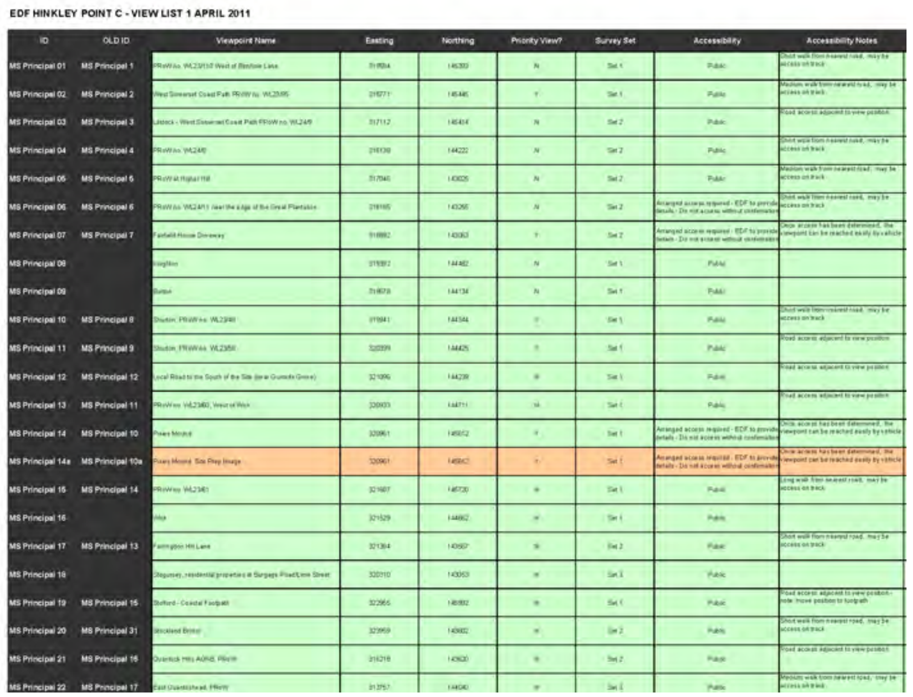
4.5 Professional survey marking materials were used to mark and maintain each view location. The type of survey marker utilised was dependent on the ground surface conditions.

4.6 Each marker was photographed and recorded for reference purposes.

4.7 Appendix 1 and 2 show the viewpoint locations and viewpoint details.



Viewpoint planning

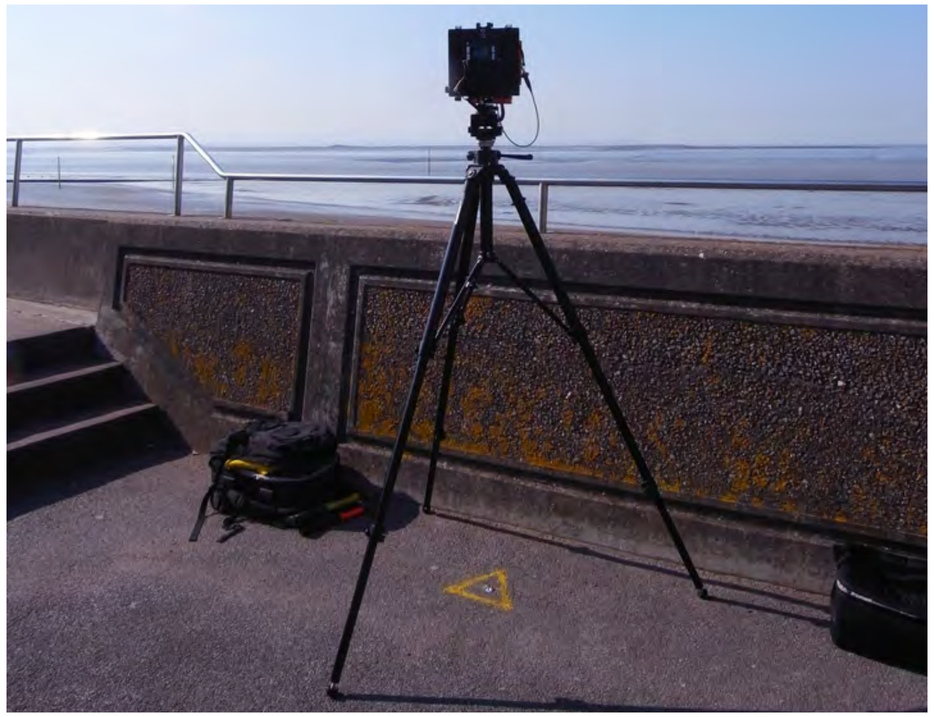


Record keeping

Accurate viewpoint location

5 Photography

Professional architectural photography equipment



Camera in position

Accurate viewpoing matching

5.0 All photography was carried out by a professional architectural photographer fully briefed, trained and audited in the capture of photography for verifiable imagery

5.1 For each image the photographer used the following equipment:

Camera: Arca Swiss F-Compact 6x9 Camera

Digital Back: Phase One P45+

Lens: 35mm Schneider Apo Digital Lens

The images were processed initially by the photographer to achieve results that best reflected the experience of each scene at the time of the photography.

5.1 The scenes were photographed using the survey markers to accurately identify the view locations. A plumb line was used to ensure that the centre of the camera was directly over the surveyed viewing positions at a height of 1.70 metres. A log was kept of the time and date that the photographs were taken so that lighting conditions could be recreated in the computer model.

5.2 There is no single definitive camera and lens format that is suitable for all planning photomontage work. Choices need to be made with care and clearly explained through method statement / annotation. Single panel landscape photography taken with a 40º lens (50mm lens / 35mm camera) is most often likely to be inadequate for purpose and is not recommended as it may be unrealistic. If chosen appropriately, correctly annotated, and with professional understanding by those assessing, there is little to be lost by using wider angle lenses (up to 70º), as this can add peripheral information that more closely reflects the viewers 'experience' of a scene.

5.3 Very wide angle single lens views can minimise impact and as such this technique is also inappropriate. Through a careful choice of lenses that allow wider fields of views, landscape is able to be better assessed. The use of hybrid lenses/photographic solutions (ref. Multi-Lens section 9.2) ensure that distortion issues can be minimised for panoramic images.

Hayes Davidson recommends that all parties are mindful that Environmental Statement photomontage should be used as a compliment to site based assessment.

6 Surveying

6.0 During the site visit Hayes Davidson identified key static points such as building corners, road edges and street furniture that would be visible within each photograph. A chartered measured engineering surveying company surveyed the points as described below and the information was issued digitally.

6.1 Additionally, the surveyors identified 3 or 4 objects within the scene, which fell along the horizon line of each photograph. Numbered camera positions were surveyed using line of sight surveying and aligned to the local site grid in easting, northing and elevation supplied by the architect and to the Ordnance Survey National Grid (OSGB36) in easting and northing, and in elevation to the Ordnance Survey Datum (OSD) using the OSTN02 GPS transformation.

6.2 A line of sight, two station baseline is established, coordinated and levelled utilising GPS observations.

6.3 The survey control stations are either observed by GPS or traversed from GPS-observed points. The Leica Smart Net GPS correction service was used to capture and transform the data from the WGS84 universal GPS coordinate system to the Ordnance Survey National Grid (OSGB36) National Grid using the OSTN02 transformation and is accurate in both position and height. Relative height accuracies comparable to geodetic levelling can be achieved, without visiting any existing OS bench marks.

6.4 A Total Station capable of measuring horizontal and vertical angle observations combined with an internal co-axial non contact distance measuring device accurately measured and stored the three dimensional coordinates of the key features from the control stations.

6.5 The required horizon line within the image is established using the horizontal collimation of the Total Station. The horizon line coordinates were surveyed and stored.

6.6 Surveying equipment used:

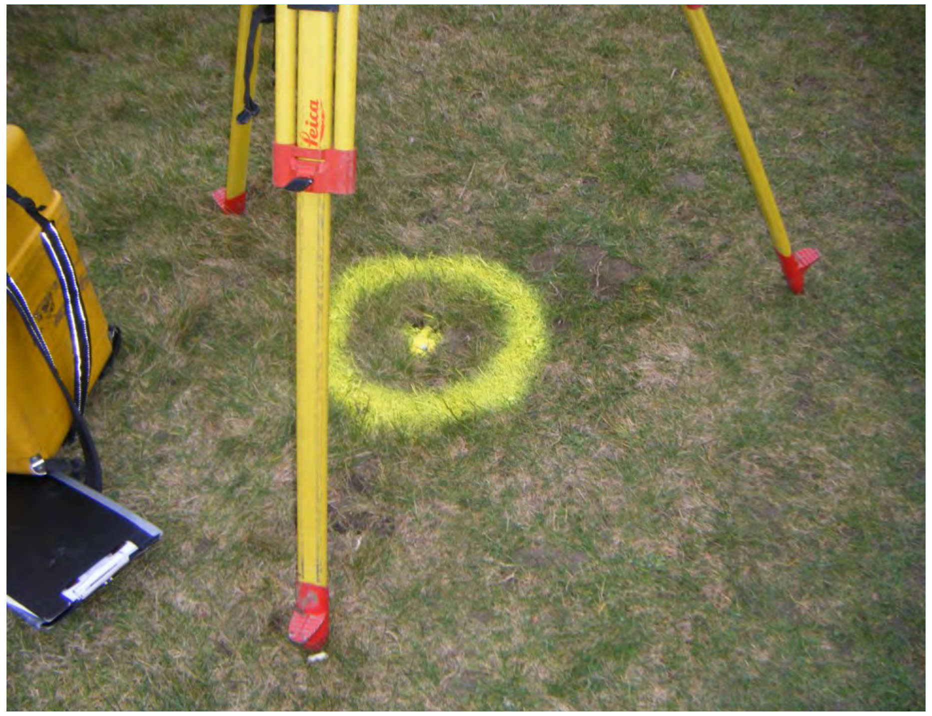
GPS - Leica GPS / TCR 1200 Smart Station.

Trimble 5600 Reflectorless Total Station with a 5” angle measuring accuracy and 3mm + 2ppm distance measuring accuracy.

6.7 Processed Data Delivery:

Coordinate and level data in Excel file format, together with DWG and JPG files detailing the observed points and the horizon line.

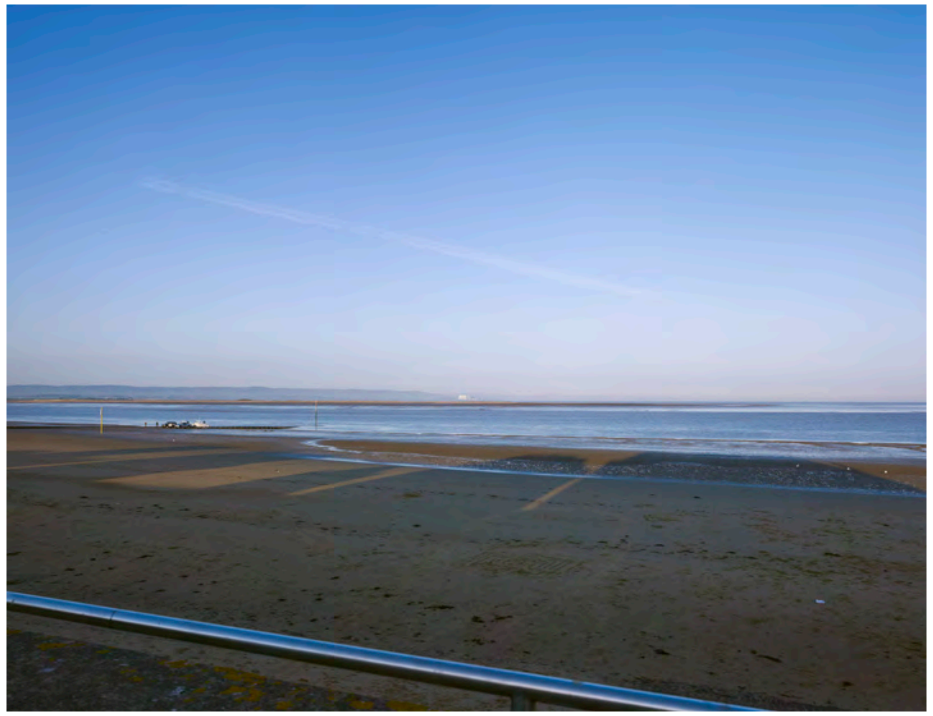
On-site surveying



Accurate viewpoint matching

Context point surveys

7 Colour correction and baseline adjustment



Uncorrected image as supplied by photographer

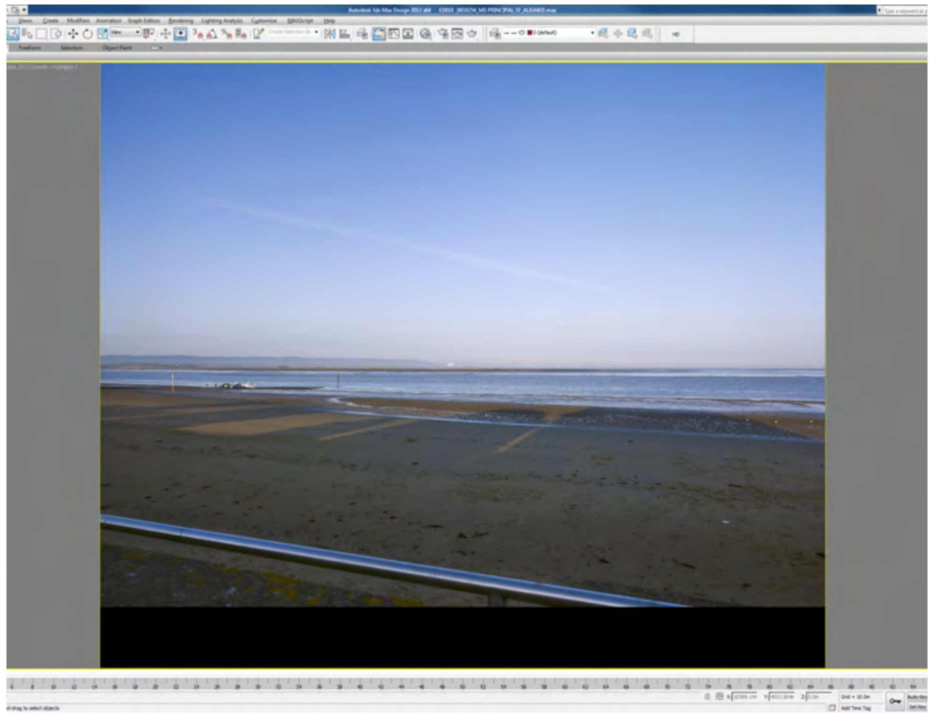


Image being corrected in 3D software

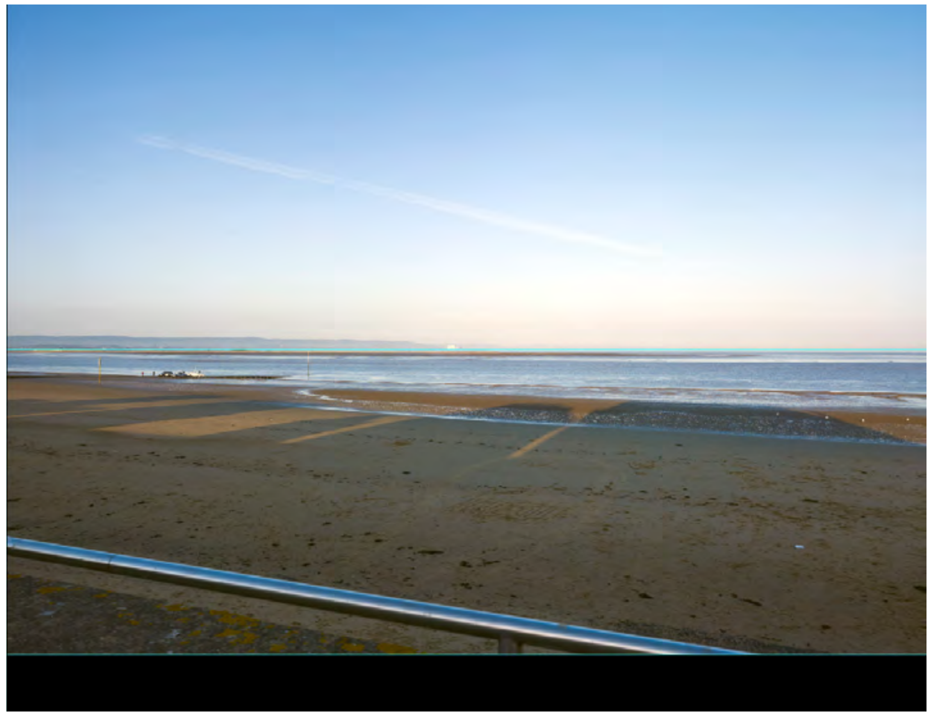


Corrected horizon and colour

7.0 All baseline images were reviewed by YRM, Gillespies and EDFEnergy prior to being used for the production of imagery. Where images were deemed not to be of sufficient quality for the production of imagery, the scenes were reshot by the photographer using the methods described previously.

7.0 The digital images supplied by the photographer were saved as Photoshop PSD files for use in the verification process.

7.1 Using the surveyed horizon points as a guide, the images are checked and rotated, if necessary, to ensure that the horizon line on the photograph is level, based upon the information received from the surveying team.

7.2 Any incorrect colour 'casts' are adjusted to match the original images. Similarly the brightness/contrast ratios of the images are corrected to match the original images.

7.3 In professional architectural photography, having the camera pointing 'horizontally' (parallel with the ground) is desirable to ensure that vertical elements of the photographed scene remain perpendicular to the horizon. In reality the eye and brain compensate for non-perpendicular verticals and it is desirable to replicate this with photography. The tripods used by professional architectural photographers have built-in spirit level 'bubbles' to assist the photographer in keeping the vertical building elements 'vertical'. The photographer also uses a secondary spirit level to check the verticality through 360 degrees.

7.4 Following from 7.3 above, the cameras used by professional architectural photographers have the ability to 'shift' the back of the camera upwards which removes the 'static' nature of having the horizon midway along the vertical dimension of the photograph (as opposed to a standard 35mm camera) and allows for the inclusion of more sky over immediate foreground. This is standard practice within architectural photography and more realistically reflects the viewer's experience on site. The photographer employed this technique at his discretion and recorded the results of each shift, where used.

7.5 The 'virtual' cameras in proprietary 3D software typically do not have this 'shift-negative' feature and so their horizon line will always bisect the vertical dimension of the view when the camera's view cone is positioned parallel to the ground plane. Consequently the baseline images are further resized to ensure that the surveyed horizon line bisects the background image in the vertical dimension

8 3D digital modelling

8.0 All drawn and digital information regarding the proposed development was supplied to Hayes Davidson in digital and hardcopy format by YRM Architects and Gillespies Landscape Architects.

8.1 For each building or structure, YRM Architects provided plans, sections and elevations that detailed the proposed construction.

8.2 The ground level and height of each building or structure was provided on the sections and elevations measured in metres and in metres Above Ordnance Datum (mAOD).

8.3 For the position of each building, YRM provided a masterplan drawing in digital format that located the footprint of each building based on Ordnance Survey National Grid.

8.4 Materials information was provided by YRM in digital format as PDF and JPG. Colour information for solid materials was provided with colour references and precedent images. Coloured elevations were also supplied in digital format for reference.

8.4 On site landscaping details was provided by YRM Architects in digital format. The plans and sections provided showed levels in mAOD format together with delineated material boundaries and finishes.

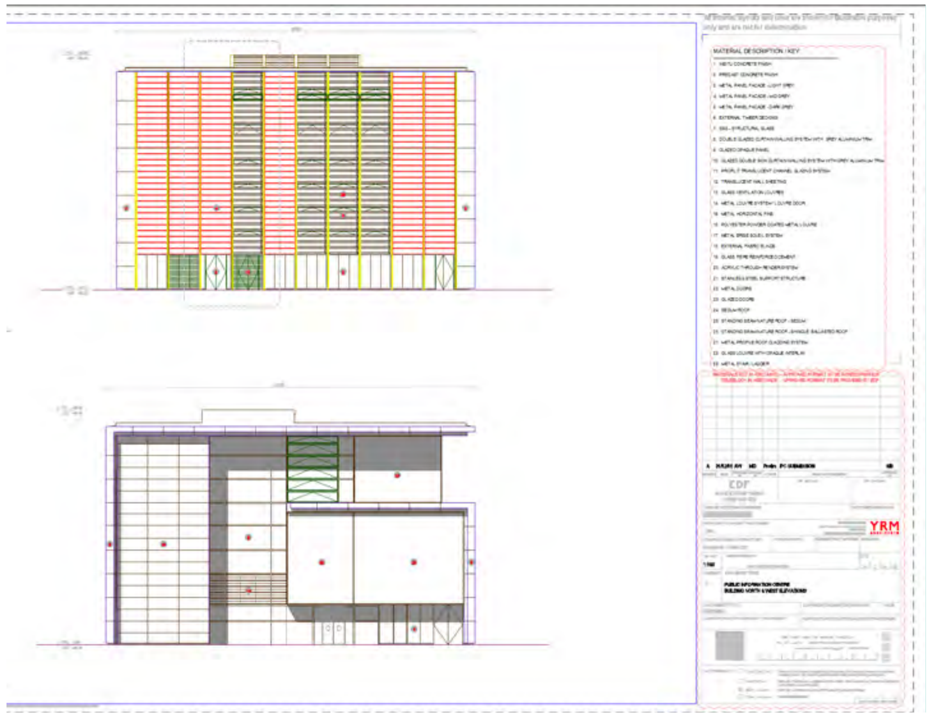
8.5 Off site landscaping details were provided by Gillespies Landscape Architects. Plans in digital format showing the location of each area of planting were provided. Further plans were provided in 3D digital format of the proposed landform terrain.

8.6 Precedent images and species information were provided by Gillespies Landscape Architects for each element of landscaping. Growth heights for each area were provided in tabular format.

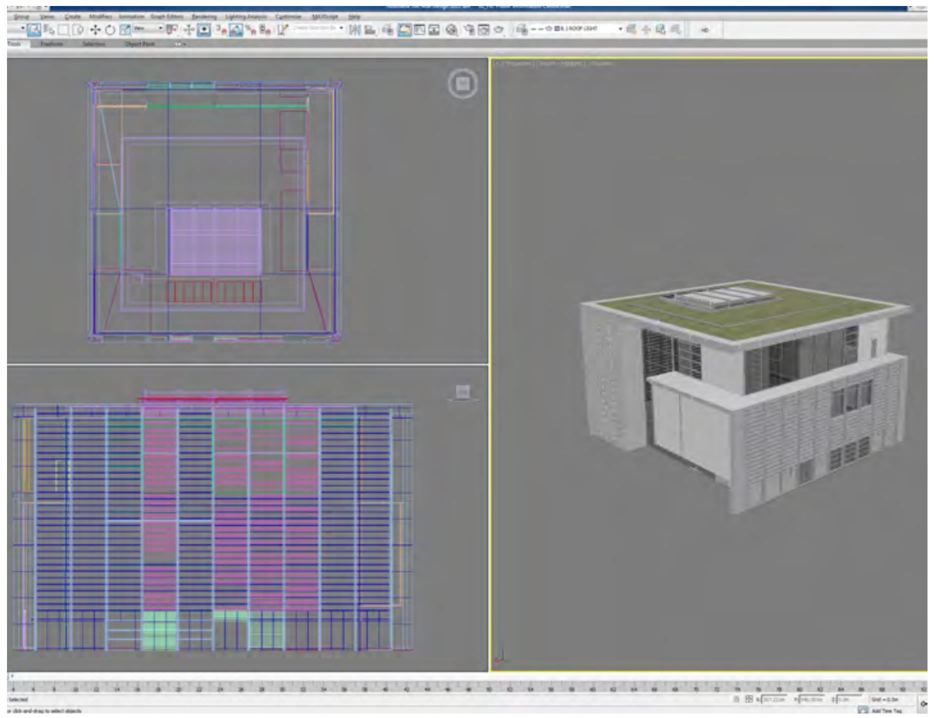
8.7 It was requested that part of the site be shown with landscape growth at 15 years, part at 20 years and part at 25 years to allow for advance planting works that would take place prior to construction of the main site.

8.8 All of the supplied information was modeled in 3D using 3DS Studio Max modeling software. The information was checked internally by Hayes Davidson against the provided information and externally by YRM and Gillespies.

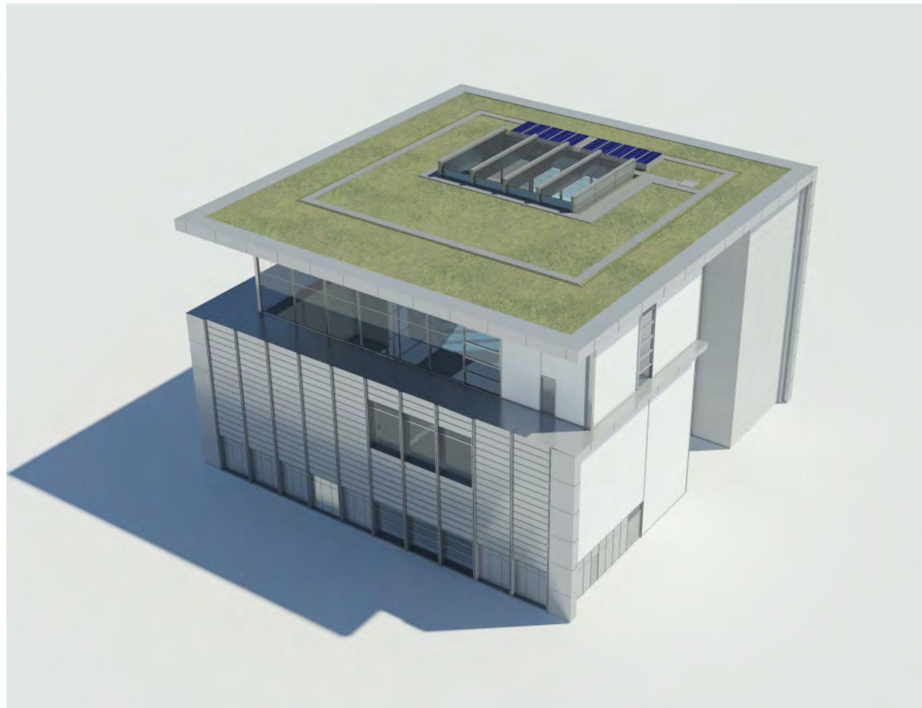
8.9 Appendix 3 shows the buildings located on the final masterplan.



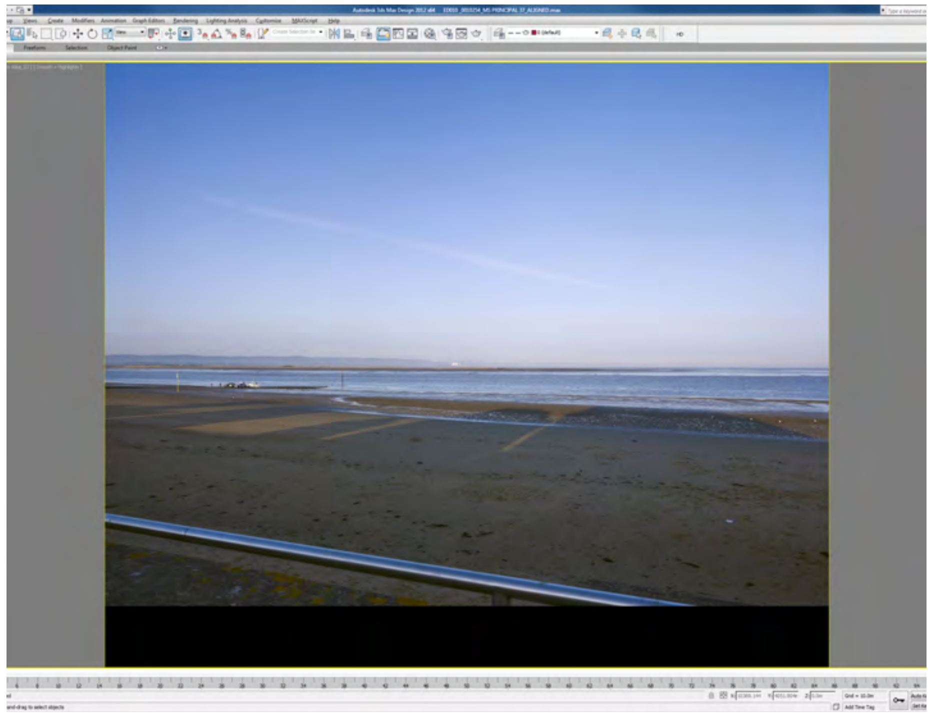
Supplied 2D drawings



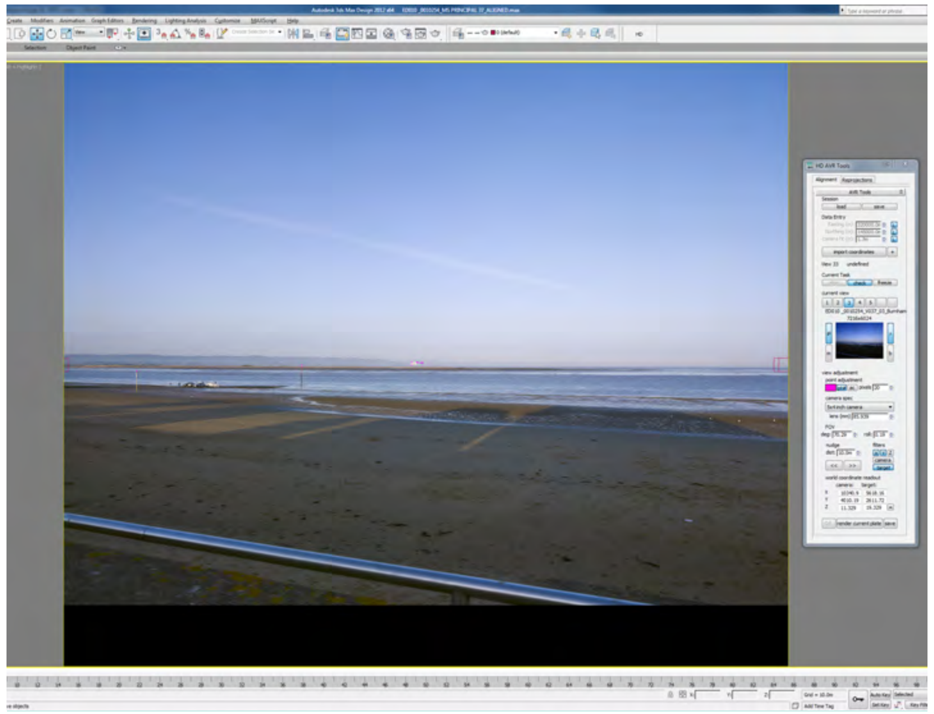
Modelling of structures



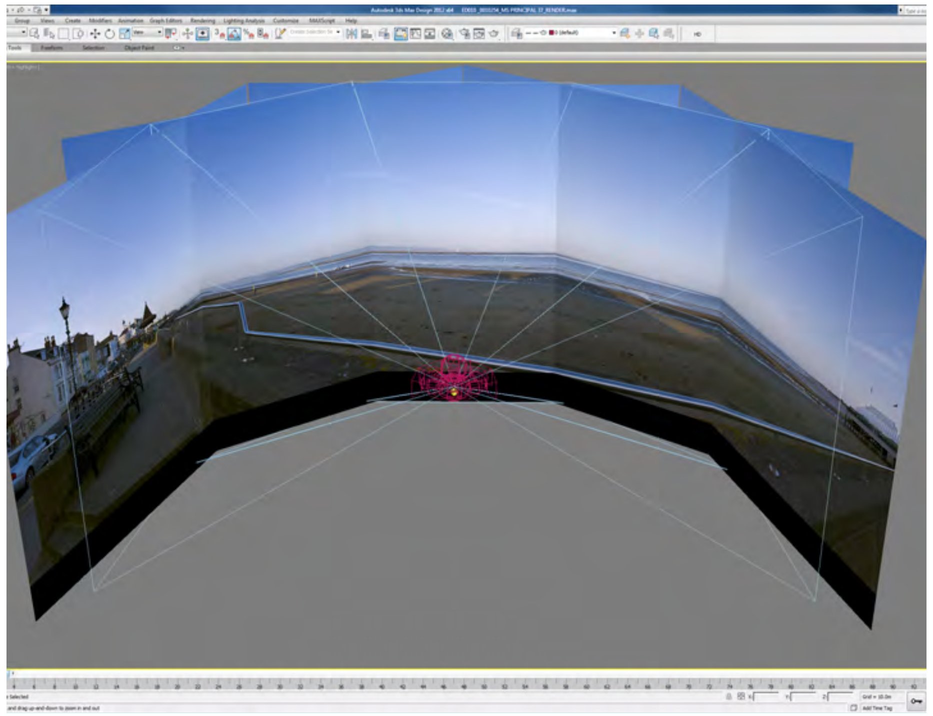
3D model



Background plate



Alignment script



Multi-lens

Surveyed context

9 Camera matching / alignment

9.0 For each view position a virtual camera was set up in the 3D software using the coordinates provided by the surveyor. The 3D coordinates of the additional surveyed verification points were used to create an accurate model of the contextual surveyed parts of the scene.

9.1 The scene was verified by matching the contextual surveyed points between the data scene and the photographers corrected baseline photograph. The contextual survey points were used as a check against the target position and the field of view of the virtual camera.

9.2 Where multiple images are required to create wider scenes, Hayes Davidson use a technique developed in-house called Multi-Lens.

9.3 Each individual image was aligned using the process above. The virtual cameras are then merged into a single scene in the 3D software, thus creating a merged wide image. This technique reduces the distortion caused by using wider lenses.

9.4 The 3D models of the proposal are then referenced to each verified camera scene.

10 Image production

10.0 During image production, the computer generated images, or 'render' of the proposed building are combined with the background photographs using proprietary digital compositing software.

10.1 Whilst position, height and scale will be objectively accurate, subjective judgement must be used when lighting is being assessed and therefore a definitive and objectively verified agreement on lighting is not possible.

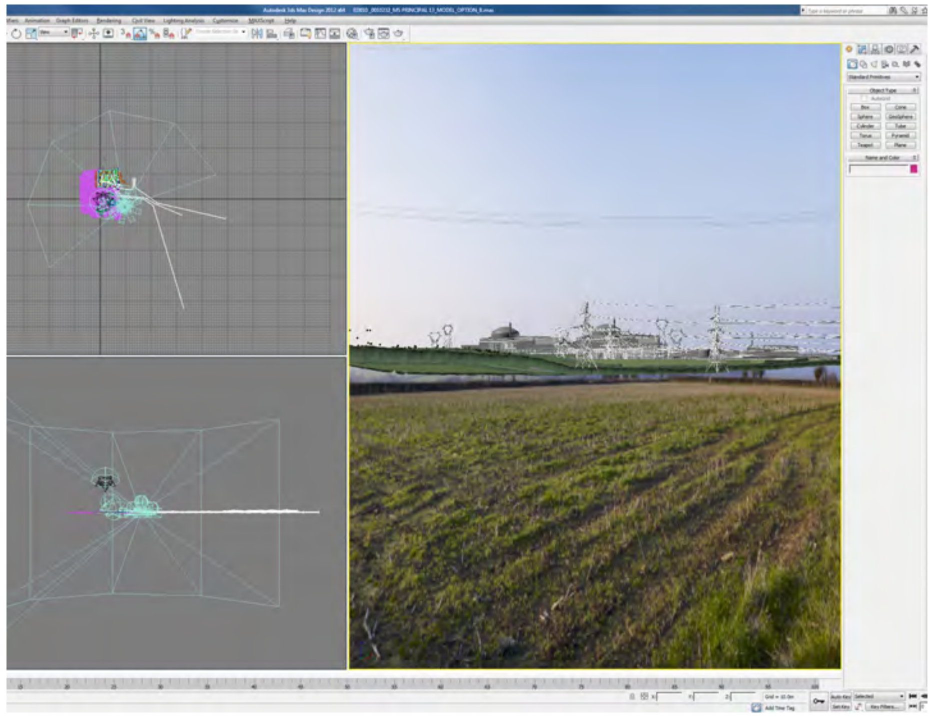
10.2 In fully rendered views, a lighting simulation is used to determine the direct sunlight component within the scene. The simulation model is a mathematical process that uses latitude, longitude, building orientation, date and time to create an accurate sun position within the 3D computer scene.

10.3 Material characteristics were applied to the models to replicate those being used in the proposed buildings. Materials within the photograph, similar in nature to those being proposed, were examined to establish how the new building would look in the photograph.

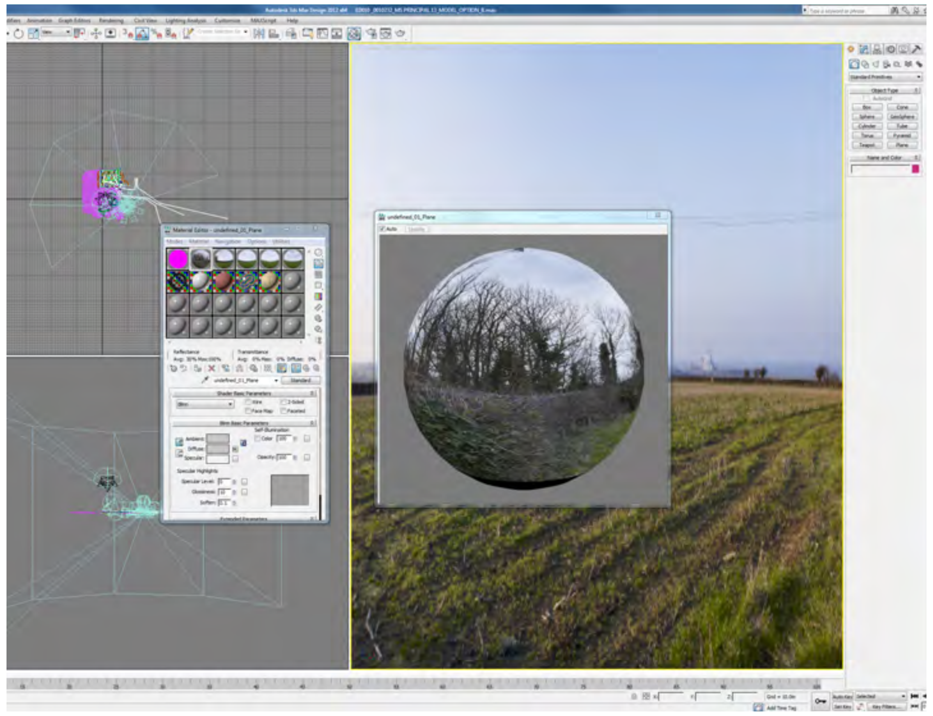
10.4 Using the verified camera described previously, the computer produces an image, known as a render, of the proposals using the geometry, material and lighting definitions specified. The materials and appearance is then approved by the architectural team.

10.5 Buildings with a similar orientation to the proposed building within the scene were used as a reference to obtain visual clues as to how the light would react with the proposed building. Materials within the scene, similar in nature to those being proposed, were also examined to establish how they react to the prevailing lighting condition. Consideration was also given to the proposed building surface types, level of transparency/reflection of the building envelopes and the angle of the reflective surfaces to the camera.

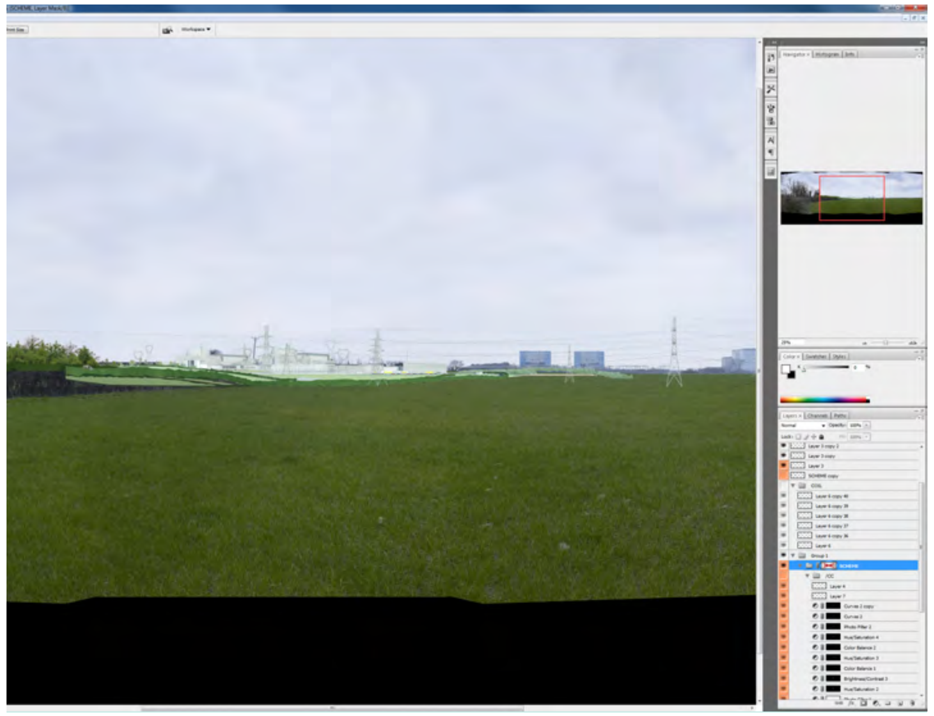
10.6 Hayes Davidson analysed each scene and assessed tonal values. We used the computer software functionality to take multiple digital samples of values for hue, saturation and brightness from a number of scenes in the photograph. From this an analysis and assessment of the likely tonal and colour values in the scene was made.



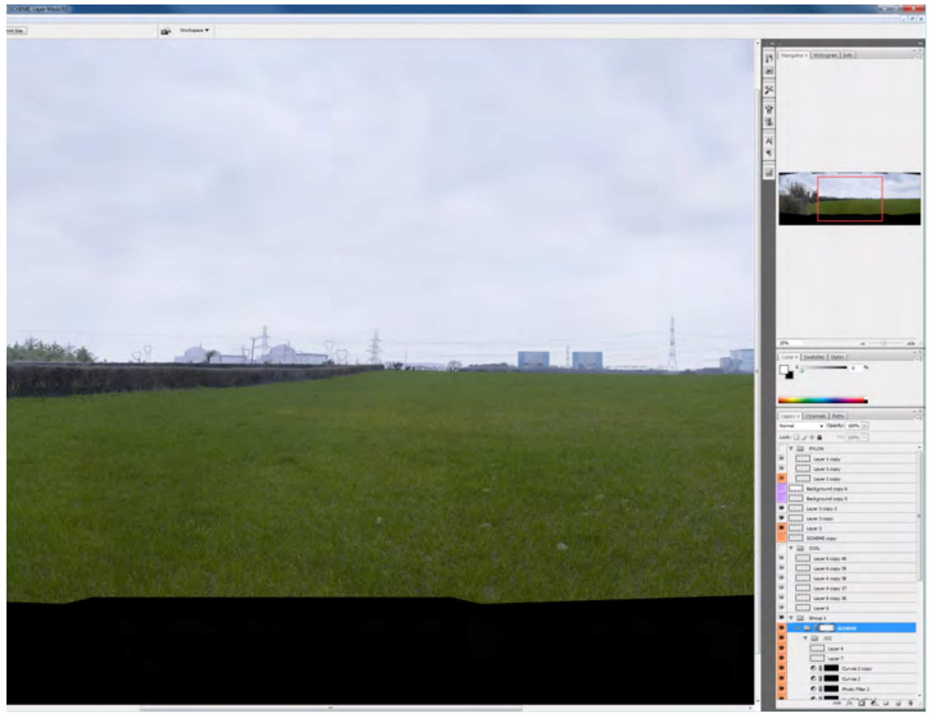
On-site photography



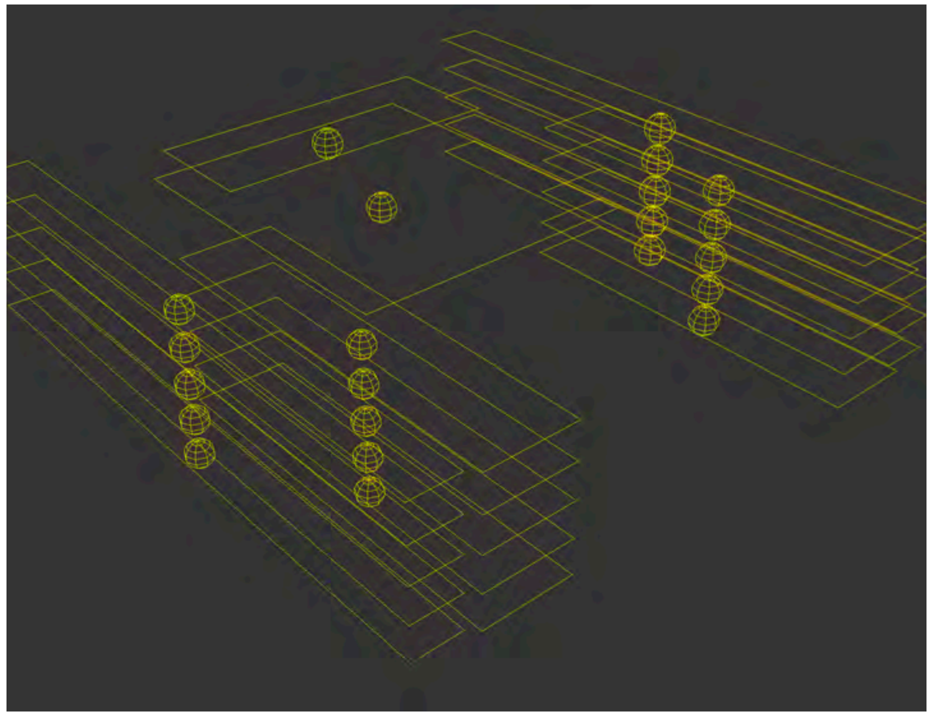
Modelling of structures



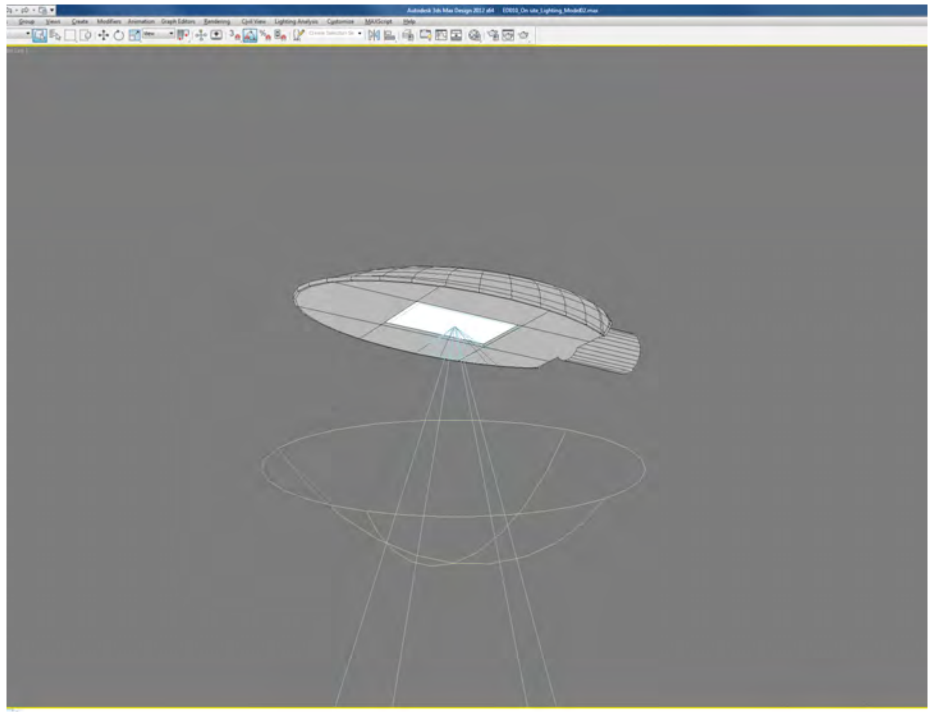
Accurate viewpoint location



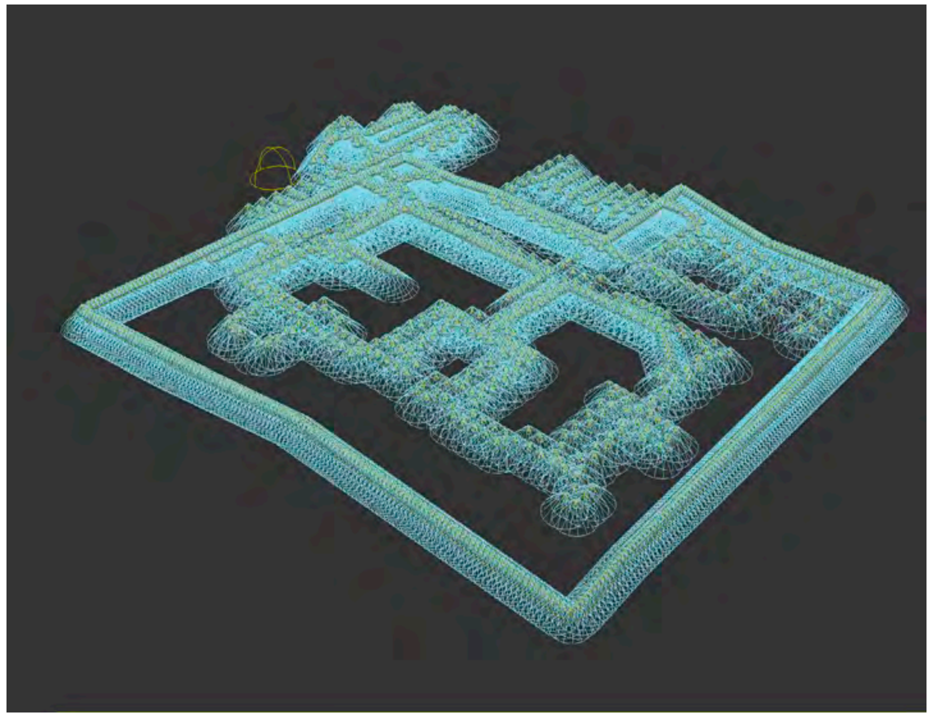
Terrain modelling



Lights positioned in floor plates



Modelled exterior light fixture



Position and influence of exterior lighting in 3D

Dusk view close-up

11 Dusk Images

11.0 Thirteen of the agreed viewpoints were required to be shown in dusk lighting conditions.

11.1 The 13 viewpoints were agreed with the statutory and local consultees,

11.2 Each viewpoint was visited by the photographer at dusk, the photographer setting up over the agreed view position marker as previously described.

11.3 Each scene was captured in the same way as previously described using a series of overlapping image panels.

11.4 It was essential that the photographer achieved a clear view of the proposed site area at a time where physical elements would still be visible in order to aid the camera matching process.

11.5 The digital 3D models built for each part of the proposal and used in the production of the daylight images were used for the production of the dusk images.

11.6 In order to represent light spill from the interior of proposed buildings, floor plates and lighting were added to the interior of each building where light spill would be seen.

11.7 For each enclosed floor area a single light at a lux/lumen value of 500 has been placed in the centre of the area. A lux/lumen value of 500 is recommended as being appropriate for interior office environments by The Chartered Institution of Building Services Engineers.

11.8 For exterior lighting, 2D drawings and specifications were provided by YRM for each individual ground placed lighting column. Each of these lights was positioned in the 3D model at the provided location.

11.9 The physical geometry of each light was modelled to accurately reflect the behaviour of the light when placed in real world conditions. This was deemed more accurate than using simulated lighting via a 3D rendering package.

11.10 All lumen outputs, heights intensities and directions were modelled based on the supplied 2D information.

12 Real scale viewing

12.0 It is important to remember that Accurate Visual Representations should be treated as an aid to visual assessment and are not a substitute to site based assessment of an individual scene.

12.1 When assessing a development using Visually Verifiable Images the scale of the development in the scene should be taken into account together with what the human eye will experience at the scene.

12.2 The aim of Visually Verifiable Images is to represent the landscape or townscape context or proposed develeopment that is under consideration as accurately as is practically possible.

12.3 The Visually Verifiable Images produced by Hayes Davidson for the Hinkley Point C development have been produced in accordance with Landscape Institute Guidelines advice note 01/2011, based on the following criteria that the images should :

- be reproduced at a size and level of geometric accuracy to permit impact assessment, which must include inspection at the location where the photograph was taken;

- be based on a replicable, transparent and structured process, so that the accuracy of the representation can be verified, and trust established;

- use techniques, with appropriate explanation, that in the opinion of the landscape professional best represent the scheme under consideration and its proposed environment accurately as possible;

- be easily understood, and usable by members of the public and those with a non-technical background;

- be based on a good quality photographic image taken in representative weather conditions

12.4 In order to assess the images at a size and resolution suitable for use in assessment work in the field the images have been prepared with a field of view and viewing distance that accurately reconstructs the perspective and scale of elements experienced at the scene.

12.5 A viewing distance of 400mm was chosen for the final printed versions fo each of the Visually Verifiable Images. This distance is at the middle of the recommended 300-500mm viewing distance proposed by the Landscape Institute Advice Note 01/2011.

12.6 A horizontal field of view of 160 degrees and a vertical field of view of 55.5 degrees was chosen for each of the final printed versions of the Visually Verifiable Images. Combined with the vewing distance of 400mm this gives the assessor the opportunity view the proposed development a t a scale, resolution and perspective that closely matches that experienced at the scene.

12.7 As advised by the Landscape Institute Advice Note 01/2011 the method for determining the viewing distance has been calculated using Scottish Natural Heritage's Good Practice guide for the representaion of windfarms SNH 2006, para 126.

Panoramic image examples

13 Notes

Subject to accurate survey information, the position and scale of a building in a scene can be verified mathematically. Whilst position, height and scale will be objectively accurate, subjective judgement must be used when lighting is being assessed and therefore a definitive and objectively verified agreement on lighting is not possible.

The computer can accurately assess the relative contrast between the faces of a building at a particular time. The computer can also render approximate material definitions. However, not every aspect of what is seen visually on screen is able to be simulated using an automatic or wholly objective process. Reflected light, local lighting conditions, detailed material definitions, climatic conditions including moisture content of the air both across the scene as a whole and locally cannot be accurately assessed or simulated by current computer technology. We therefore turn to the scene for visual clues in order to set the render of the proposed development into the photograph.

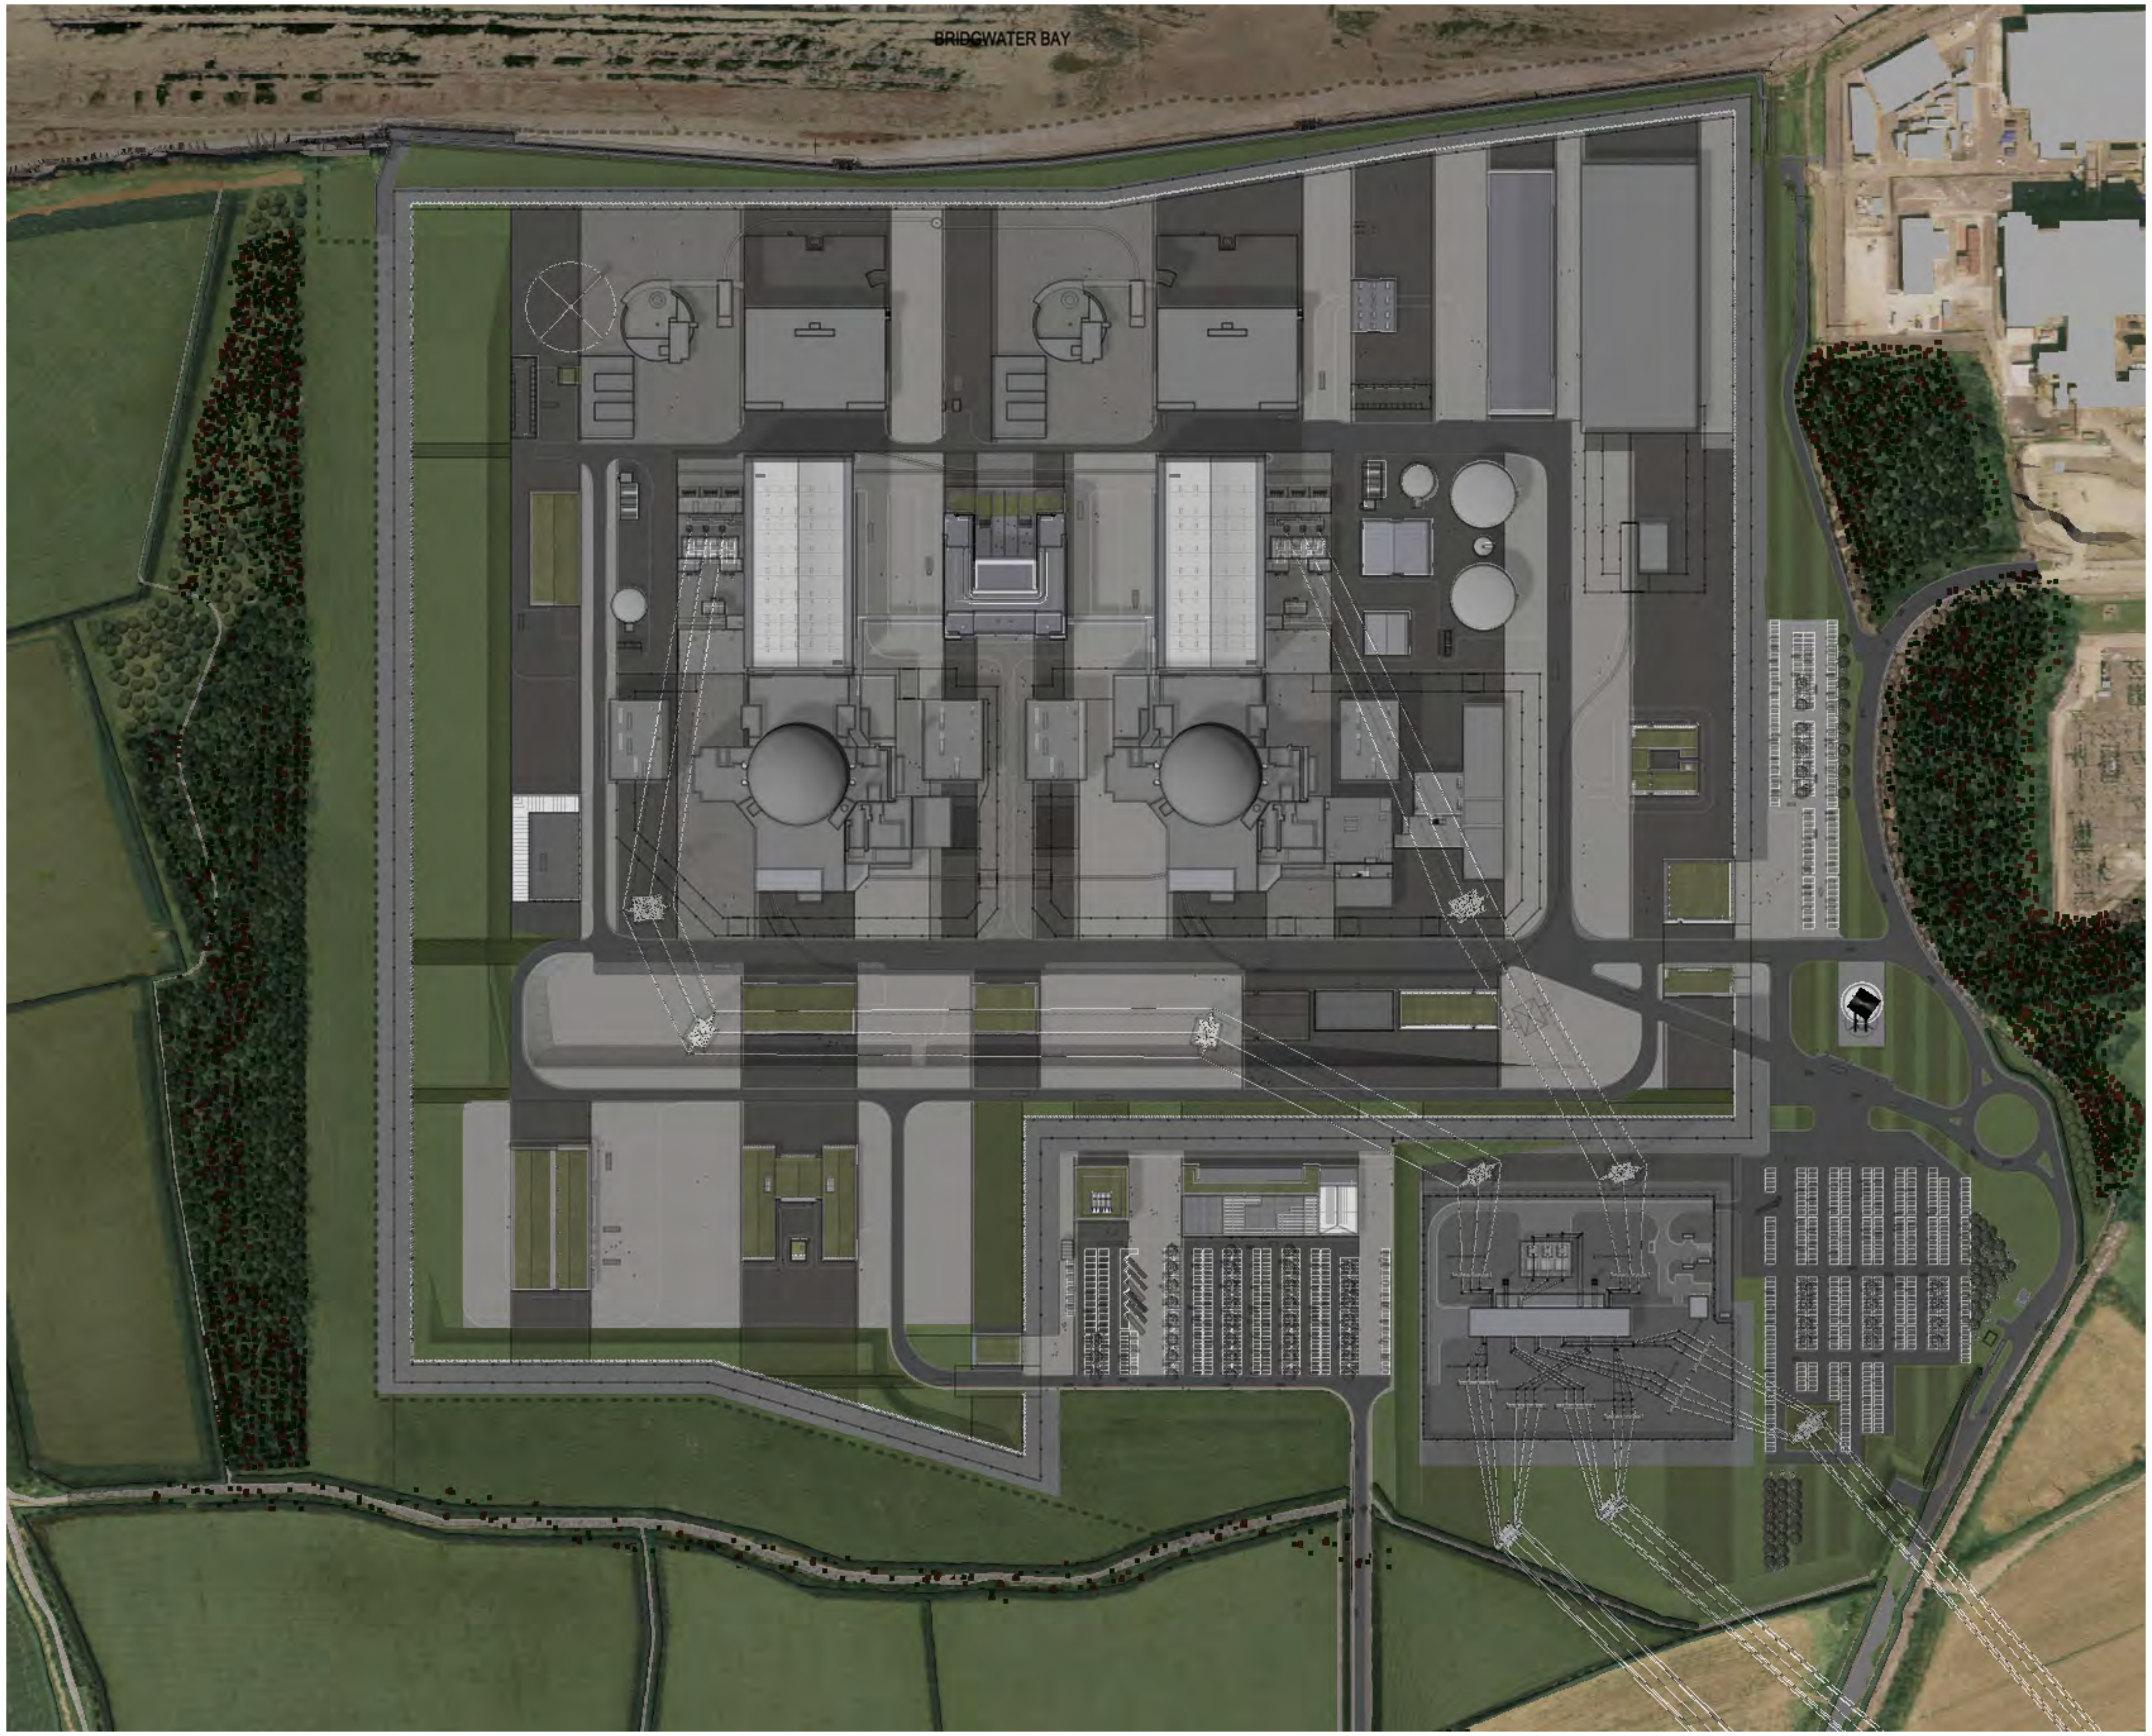
Appendix C

Masterplan overlay



Calculating the correct viewing distance

B22 The correct viewing distance is the distance at which the perspective in a photograph (or photomontage) correctly reconstructs the perspective seen from the location from which the photograph was taken. It also follows that, as seen from the correct viewing distance, the photographic image will occupy the same horizontal angle as the horizontal field of view it represents. This is true of both single-frame and panoramic photographs.

B23 The single-frame case is simpler geometrically. Seen from above, the photograph is merely a straight line of length **w**. We can construct an isosceles triangle with the apex representing the viewpoint and the height of the triangle, **d**, representing the viewing distance. At the correct viewing distance the apex angle, **A**, of the triangle must correspond to the horizontal field of view of the photograph. The correct viewing distance is then given by:

$$d = \frac{w}{2\tan\left(\frac{A}{2}\right)}$$

(single frame only)

where:

d is the correct viewing distance in mm
w is the image width in mm
A is the horizontal field of view in degrees
tan is the trigonometric tangent function

B24 If the horizontal field of view and the required viewing distance is known, then the formula rearranges thus to give the image width:

$$w = 2d\tan\left(\frac{A}{2}\right)$$

(single frame only)

B25 Finally, if the image width and viewing distance are known, the formula can also be arranged to give the horizontal field of view. (This version of the formula is useful to determine the horizontal field of view that can be accommodated on a fixed page size.):

$$A = 2\arctan\left(\frac{w}{2d}\right)$$

(single frame only)

B26 In the case of a panorama, the image is assumed to be wrapped around the inside surface of a cylinder whose radius is the correct viewing distance. The horizontal field of view must by definition therefore correspond to the arc of the cylinder subtended by the image.

B27 Given the width of the image and the horizontal field of view, the correct viewing distance is given by:

$$d = \frac{180w}{\pi A}$$

(panorama only)

where:

d is the correct viewing distance in mm
w is the image width in mm
A is the horizontal field of view in degrees
π has its usual geometrical meaning

B28 Given the viewing distance and the horizontal field of view, the image width is given by:

$$w = \frac{\pi A d}{180}$$

(panorama only)

B29 Lastly, if the image width and viewing distance are known, this formula can also be arranged to give the horizontal field of view:

$$A = \frac{180w}{\pi d}$$

(panorama only)

APPENDIX 22C: TREE AND HEDGEROW SURVEYS AND ASSESSMENTS

Appendix 22.C

Tree and Hedgerow Surveys and Assessments

Woodland

All woodland blocks within the HPC development site have been surveyed to BS 5837; 2005 Trees in relations to construction - Recommendations. Please refer to Tree Survey Hinkley Point C Development Site March 2011. The site is generally exposed to the prevailing north-westerly salt-laden winds from the Bristol Channel. As a result, the coastal woodland brakes have a wind-sculpted profile. Individual trees have strongly asymmetrical crown spreads, and achieve limited height. Brakes adjacent to the coast have waterlogged soil, and many brakes are on thin soil. Elm trees are subject to Dutch Elm Disease as they grow up. Agricultural activity in adjacent fields within tree root zones further limits establishment. Consequently many trees are prone to windthrow, and tree quality within the coastal brakes has been assessed as generally low. Bishops Wood south of Green Lane is in a more sheltered position, further inland. Recently planted on former agricultural land, Bishops Wood has better quality trees, but no trees have achieved 150mm diameter yet.

All woodland has also been assessed to establish the value of the woodland as ecological habitat through a Woodland Condition Survey. Please refer to Hinkley Phase 1 Habitat Survey Report August 2009. The Woodland Condition Survey concludes that the woodlands characteristics of small size, isolated location and species-poor composition are of local to district value for biodiversity.

Woodlands on site have been assessed, and there are no ancient woodlands (defined as land continuously wooded since 1600 AD). For more details of historic landscape please refer to the Cultural Heritage Desk-Based Assessment July 2009 and ES Chapter 23 Historic Environment.

Hedgerows

All hedgerows on site have been assessed under The Hedgerows Regulations 1997 to establish their importance in terms of ecology and archaeology. The Hedgerow Regulations identify the criteria against which the ecological and historic importance of hedges can be assessed.

The hedgerows were assessed for ecological importance. This assessment covers all hedgerows considered to be over 30 years old. For each hedgerow a 30m section (per 100m of hedgerow) was surveyed and information on location, dimensions, number of woody species, any hedgerow features, connectivity to other features and ground flora species were recorded.

The ecological hedgerow assessment concluded that two-thirds of the hedgerows were found to be ecologically important, including Green Lane and parts of Benhole Lane and Wick Moor Drove hedgerows. For more details, please refer to Hinkley Phase 1 Habitat Survey Report August 2009.

The hedgerows were assessed for archaeological importance. This assessment identifies all hedgerows over 30 years old which also satisfy at least one of the relevant archaeological criteria, such as forming part of an historic boundary or pre-enclosure field system. For more details please refer to the HPC Cultural Heritage Desk-Based Assessment July 2009.

The archaeological hedgerow assessment concluded that one-third of the hedgerows were found to be archaeologically important, including Green Lane and part of Wick Moor Drove hedgerows, and other hedgerows on the coastal slopes.

Further Surveys

Trees and hedgerows to be retained and managed within the proposals for Construction Works have been surveyed to BS 5837 2005; 2005. This survey covers Green Lane, Benhole Lane and Wick Moor Drove hedgerows and trees. Please refer to Tree Survey Hinkley Point C Development Site July 2010.

The outcome of this survey identifying the quality and value of these trees and hedgerows will inform their management. The survey identifies the Root Protection Area which will inform the location of the tree protection required during the construction period to the standards set out in BS 5837 2005. All construction access/works will be excluded within those areas, apart from arboricultural management. The protective fencing footings will be outside of the root protection area.

Further Surveys

The Tree Retention and Removal drawing identify the tree blocks and the pattern of hedgerows across the site. The complexity and scale of Hinkley Point C project requires that the majority of the vegetation within the construction site would be removed within the application site for construction of HPC.

The woodland and hedgerows proposed to be removed are identified on Figure 1 Construction Works Tree & Hedgerow Retention and Removal.

Existing hedgerows and trees which form the boundaries of the site will be retained, protected and managed for landscape amenity and biodiversity values. They will also provide habitat connectivity for foraging bats and visual screening of the site.

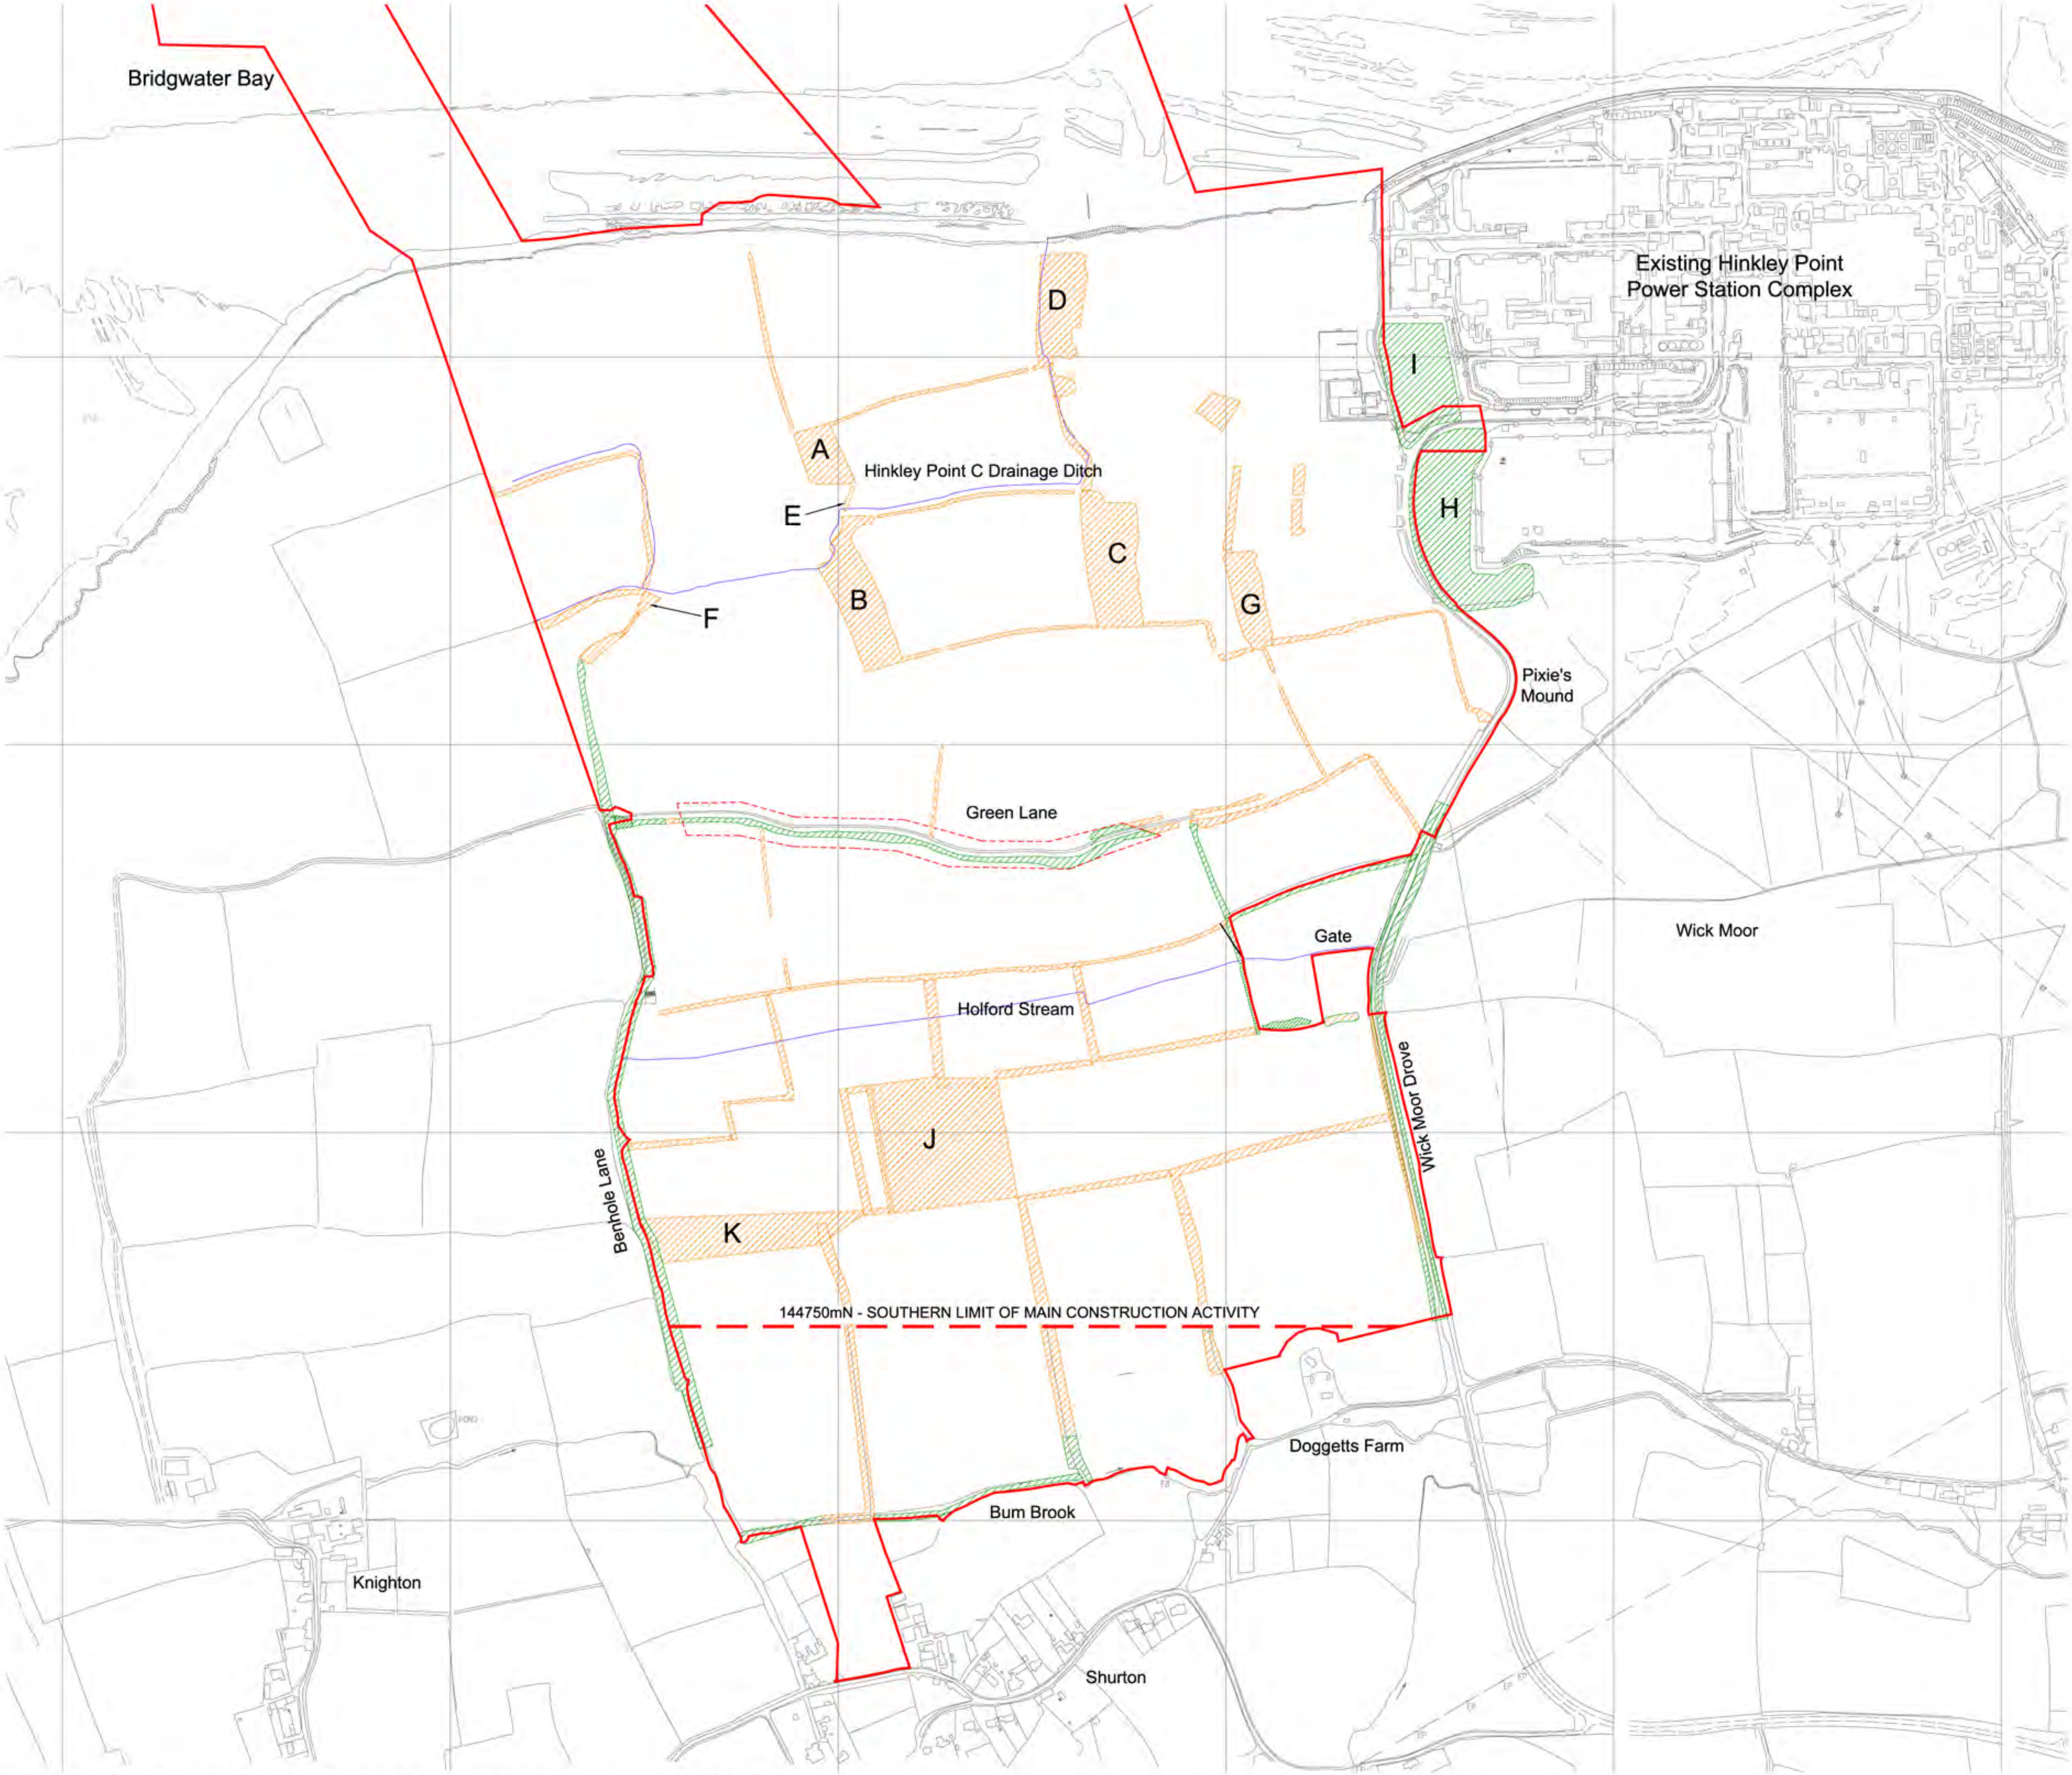
Green Lane and its hedgerows are recognised both as a prominent historic feature as well as an important east-west bat corridor, and will be largely retained, protected and managed throughout the construction period through an exclusion zone marked with a fence to BS 5837:2005. Two breaches in the hedgerows are proposed for access to site areas north and south.

The eastern end of Green Lane will also be removed but adjacent hedgerows will be retained to provide habitat connectivity for bats to the east.

Benhole Lane hedgerows are recognised for their historic value as part of the historic trackway and will be retained and protected.

Wick Moor Drove western hedgerow will be largely retained, protected from the impacts of construction and managed during the construction period. Sections of the hedgerow will have to be removed to provide access to the site from Wick Moor Drove; these areas are identified as removed on the tree retention and removal drawing. A diverted footpath within a 4m zone is proposed to run inside the Wick Moor Drove hedgerow for the length of the site. The site security fence will form the inside boundary to the footpath.

The landscape restoration has been designed to mitigate for the temporary loss of valuable wildlife habitats such as woodland and hedgerows. The restoration landscape includes an increase in species-rich hedgerows, and an increase of more than 350% in broad-leaved woodland, in order to mitigate for the long time taken for these slow growing habitats to establish.



Key

- HPC Development Site Boundary
- Green Lane Protection Zone Fence
- Trees and Hedgerows to be Removed
- Trees and Hedgerows to be Retained

Woodlands:

A - Newclose Covert
B - Haysgrove Brake
C - Seaburton Brake
D - Whitewall Brake
E - Unnamed woodland
F - Unnamed woodland
G - Govetts Copse
H - Branland Copse
I - Branland Copse North
J - Bishops Wood
K - Unnamed woodland

CONTENTS

APPENDICES

1. INTRODUCTION

This report and associated tree survey was commissioned by EDF Energy in March 2011 in response to a request by West Somerset Council made under Regulation 19 of the Town and Country Planning (Environmental Impact Assessment) Regulations1999 for a BS5837 Survey to cover the whole of the application site. This report supplements the previous survey (Adas, 2010) *Tree Survey Hinkley Point C Development Site* and reports on the following areas (plans are show in the appendices):

- Whitewall Brake (also known as Woodland 1),
- Seaburton Copse (Woodland 2),
- Govetts Copse (Woodland 3),
- Haysgrove Brake (Woodland 8),
- Newclose Covert (Woodland 9),
- Bishops Wood (Woodland W); and,
- Bum Brook (Area 1)
- Trees within Hedgerow Nos 36, 38 and 49 and adjacent to Bum Brook

Between them, these surveys provide coverage of the groups of trees on the area of the site covered by the Preliminary Works application. All of these areas are either within or border the site of the proposed development of a new nuclear power station, known as Hinkley Point C. This will lie adjacent to the existing Hinkley Point Nuclear Power Station complex in Somerset on the Severn Estuary.

The report provides a survey of trees, and other landscape features such as hedges, according to the guidance within British Standard (BS) 5837 (2005) 'Trees in Relation to Construction – Recommendations'. In order to make an unbiased assessment of the trees on site, and inline with the recommendations within BS 5837 (2005), ADAS has not been advised of the proposed planned tree removal under the current planning consent for the site.

Information about the ecological value of the trees and groups of trees has been submitted as part of the original planning application: the hedgerows and woodland on site have been surveyed and assessed by *(Entec UK Ltd, 2009) EDF Energy Hinkley Habitat Survey Report*. This report includes a Hedgerow Assessment compliant with The Hedgerow Regulations 1997, and a Woodland Condition Survey to determine biodiversity value.

2. LIMITATIONS

A topographical survey of the area, identifying trees and other landscape features, was made available during the survey. The positioning of trees on the plans was limited by the ability of the global positioning system (GPS) equipment to gain sufficient satellite signal under the dense canopies of trees within and surrounding the woodlands. Therefore, the position of these features cannot be regarded as being completely accurate.

Only features that were apparent at the time of inspection could be considered and no liability can be accepted regarding trees, hedges or their parts that were inaccessible or obscured in part or in whole.

Whilst hedges have been identified, unless there are groups of trees within them, they have not been assessed, as the grading system within BS5837 is inappropriate because it will always result in a Category C rating for the hedge. The ecological value of the hedges has been assessed according to the requirements of The Hedgerow Regulations 1997 *(Entec UK Ltd, 2009) EDF Energy Hinkley Habitat Survey Report.*

Thoughout 2007 to 2010 the site has been assessed for its potential to support terrestrial and freshwater legally protected and notable species by Entec Ltd. Where it was concluded that this potential existed, detailed species specific surveys were completed. In relation to the woodland within the site, it was concluded that there was potential for the European Protected Species (EPS) bats and dormouse to occur and comprehensive surveys for these species/species groups have been completed. For bats, this included both external and internal tree roost assessments. The results of these surveys are reported in Appendices 11-4 and 11-6 of the Site Preparation Application. A number of the trees assessed for bat roosts have tree tag identifiers and these have been noted in the tree survey result tables.

The woodlands also support badger (Meles meles) and further information is provided in Appendix 11-7 of the Site Preparation Application. Mitigation works are ongoing under a Natural England licence to relocate the badgers and this has necessitated some shrub clearance within the woodlands. Where this may affect the woodlands it has been noted in the tree survey tables.

3. SURVEY METHODOLOGY

The survey was carried out by Linda Henderson of ADAS between Monday 7th and Thursday 17th March 2011, and Thursday 30th March and Friday 1st April 2011, and with the assistance of Wynn Davis of ADAS between Monday 14th and Tuesday 15th March 2011.

The survey consisted of an inspection of the vegetation within Whitewall Brake (W1), Seaburton Copse (W2), Govetts Copse (W3), Haysgrove Brake (W8), Newclose Covert (W9), Bishops Wood (WW)and the Bum Brook (A1). The Arboricultural Survey Plan in Appendix 1 shows the extent of this survey and the detailed plans of the areas are in Appendix 2.

Section 4.2, subsection 4.2.4 fo the British Standard states that:

4.2.4 ***Trees forming groups*** *and* ***areas of woodland*** *(including orchards, wood pasture and historic parkland)* ***should be identified*** *and considered as* ***groups where the arboriculturist determines that this is appropriate,*** *particularly if they* ***contain a variety of species*** *and* ***age classes*** *that could aid long-term management. It may be* ***appropriate to assess the quality*** *and* ***value of such groups as a whole****, rather than individuals. However,* ***an assessment of individuals within any group should still*** *be under taken if they are open-grown or* ***if there is a need to differentiate between them.***

The above bold and underlining is ADAS' own emphasis.

As a result, the survey has identified hedgerows; groups of trees that are of a similar age class, and have been subject to the same management regime and are located in close proximity to each other; and significant individual trees. On this occasion it was considered inappropriate to place any of the trees into a woodland classification given the variation of the tree populations within the areas.

The vegetation was inspected from ground level, by eye.

The weather conditions were generally dry, bright, windy and with good visibility.

All height measurements were taken using a Haglof clinometer where there was clear visibility of the stem, base and top of the tree to be measured. Where this was not possible, height measurements were estimated by reference to heights of nearby measured trees.

The stem diameters of single stem trees were taken at 1.5m above ground level, or just above the root flare for multi-stemmed trees. Where trees were not easily accessible the diameters have been estimated; and for group of trees an average stem diameter within the group has been recorded.

4. TREE SURVEY TERMS

The survey recorded the following information for each individual tree or group of trees:

a) <u>Reference number</u>

All individual trees, groups of trees, hedges and woodlands have been given a unique reference number. Each number is prefixed by a letter.

T = Individual tree

G = Group of trees

H = Hedgerow

b) <u>Species</u>

The English common name has been used.

c) <u>Single or Multi-stemmed</u>

'S' represents a tree which has a single clear stem to at least 1.5m above ground level, whilst 'M' represents a tree where the main stem divides into at least two stems below 1.5m above ground level.

d) <u>Height in metres</u>

Tree heights are measured to the nearest half metre using a Haglof clinometer, where possible. In some instances such as in close groups of trees, one height may be measured and other nearby trees estimated from this height.

e) Stem diameter

Measured in millimetres at 1.5m above ground level for single stemmed trees or for multi-stemmed trees immediately above the root flare. Where site factors such as dense vegetation and fences restrict access to the base of a tree, the stem diameter has been estimated. This is highlighted in the tree survey schedule.

Groups of trees have been given an average stem diameter.

f) Branch spread in metres

Measured in metres to the four cardinal compass points.

g) Crown Clearance

Measured in metres between the lowest branch and the highest adjacent ground level.

h) Age class

The stage at which the tree is within its lifecycle (Y = young, MA = middle aged, M = mature, OM = over mature, V = veteran)

i) Physiological condition

An assessment of the overall health and vitality of the tree or group of trees is made and this is recorded as being either: Good, Fair, Poor or Dead.

j) Structural Condition

An assessment of the overall structural condition of the tree is made and any significant defects or features are recorded.

k) Preliminary management

Despite the fact that most of these trees will be removed, recommendations have been made where management work is required for reasons of health and safety or sound arboricultural management as this is required by the Standard. These recommendations are accompanied by timescales in which the work should be undertaken.

l) <u>Estimated remaining contribution in years</u>

An estimation of how long the tree or group of trees will contribute to its surroundings. This is recorded in bands of either <10 years, 10 – 20 years, 20 – 40 years and >40 years.

m) <u>Category Grading</u>

The trees are graded to the categories prescribed within BS5837:2005 (R, A, B & C); details of this system can be found within Appendix 3.

n) <u>Root Protection Area (RPA)</u>

Given as a radius in metres from either (1) the stem of an individual tree, (2) the edge tree of a group, or (3) the stem of a hedge. [If less than the Branch Spread, this may be extended to protect the spread of the crown].

5. TREE SURVEY RESULTS

6. DISCUSSION

6.1. General

The site is generally exposed to the prevailing north-westerly wind from the Severn Estuary. As a result many of the trees have formed adaptive growth. This has resulted in uncharacteristically small canopy spreads to the north and west, yet larger canopy spreads generally to the east; thus forming an asymmetrical crown. The winds also limit the potential height of the trees that are located on higher ground. Some of these trees which are also on thin or waterlogged soils are also prone to windthrow. All of the woodlands, with the exception of Bishop's Wood, have either fully or partially retained their original boundary earthworks, which consist of a bank and ditch. This landscape feature in conjunction with the species mix, age and method of management (the trees have often been laid) infers that the woodland is at least 100 years old. It is probable that these woodlands were originally intended to provide game cover. The majority of the woodland embankments adjoining agricultural land have experienced a change in land level (lynchet). This has been caused by ploughing and erosion moving soils away from the boundary. These factors, along with agricultural crops, which have shallow rooting systems that compete for moisture within the rooting zone of the trees, are likely to limit the ability of trees to establish and maintain roots within the adjoining agricultural land.

6.2. Wildlife

The site was assessed for its potential to support terrestrial and freshwater legally protected and notable species and, where it was concluded this potential existed, because of the habitat types present, local distribution of species, the location of the site within the UK and Europe etc, surveys were completed. In terms of the trees and woodland, it was concluded that there was potential for the European Protected Species (EPS) bats and dormouse to occur and comprehensive surveys for these species/species groups were completed between 2007 and 2010 (Appendices 11-4 and 11-6 of the Site Preparation Application).

Metal tags have been placed on those trees that have been identified as suitable bat habitat. If one of these trees has been identified within this survey, then the metal tag number has also been recorded in the tree schedule.

Further information on the bat habitat potential is contained within the report titled ‘Tree Survey for Bats Hinkley Point’ that was undertaken by Entec.

Mitigation works to remove European badgers (*Meles meles*) was evident in all the woodlands, except for Bishops Wood. These mitigation works have resulted in small to large areas of shrub and tree clearance within the majority of the woodlands.

The trees that were identified as having bat habitat potential remain *in situ*. The entrances to the badger setts have been covered with chain link to prevent the badgers returning. These areas have now been fenced off using the type of chain link fencing that is recommend within BS 5837 (2005). New deer fencing has been erected around the woodlands to exclude red deer (*Cervus elaphus*).

6.3. Statutory Controls

None of the woodland has been designated Ancient, according to a Land Information Search of the Forestry Commission's website.

Woodlands W2, W3 and WW are part of a Woodland Grant Scheme.

There are no records of Tree Preservation Orders (TPO) within the Company's management records for the woodlands. However, West Somerset Council proposed a Woodland TPO, reference W/3/118(W/1), on part of Whitewall Brake on the 4th March 2011.

6.4. Whitewall Brake (W1)

This one hectare woodland adjoins pasture to the west and east. To the south it adjoins a stone track that is also a public footpath. To the north is the South West Coast Path which is adjacent to the beach. Another public footpath runs north to south along the eastern boundary of the wood.

In the western section there are a number of water courses and drains that flow south to north, towards the Severn Estuary. Within the southern section is an area of dense brambles together with open areas. Given the water course and the Severn Estuary to the north, the majority of the western and northern sections of the woodland are considered to be wet woodland. This saturation of the soil is causing the affixation of the roots, which is resulting trees becoming moribund and dying, as within W1-G8. Furthermore, the saturation of the soil will cause root instability, and increase the risk of the trees falling over (windthrow). Examples of this are present within the northern and western sections of the woodland within W1-G1.

The trees and shrubs within the northern section of the woodland are significantly smaller than the internal trees. This stunted growth is probably caused by a combination of the soil conditions, prevailing north-westerly winds and salt spray. There are a number of fallen and decomposing large willows, oaks and field maples within the central eastern section, probably a result of windthrow.

An area of recently planted trees, which are still within their tree guards, is present in the southern section, east of the water course. Large gaps are present throughout the group, where some of these new trees have died, and these areas have become colonised by dense bramble.

Mature and over-mature oaks and field maples are present within a small area towards the central eastern section of the woodland.

The woodland contains many dead, dying or dangerous trees; indeed there are not many trees that do not fit this description, the survey tables indicate that all the trees should either be removed or are of low quality and value. The few trees that are classed as category B or above, including a number of sessile oaks have also been identified as potential bat habitat and are therefore protected from felling unless a disturbance licence is granted by Natural England. There has been a limited amount of badger mitigation work within W1; the largest area has been in and around W1-G7.

6.5. Seaburton Copse (W2)

This 0.80 hectare woodland adjoins agricultural pasture to the west and east, to the south it adjoins a mud tack and to the north is the public footpath.

There are remains of woodland embankments surrounding the woodland. The northern section of the eastern embankment is approximately one metre below the adjoining field. There are the remains of a wall in this section, on top of which are a group (W2-G2) of mature and over-mature laid field maple. These trees form the most significant landscape, and wildlife feature, of the woodland. Some of the trees have been identified as potential bat habitat.

Within the woodland there are four sites of recent ground investigation works. Hardstanding has been installed in these areas, which has extended into the Root Protection Area of some of the retained trees.

ADAS

The majority of the woodland is made up of the trees within groups W2-G3, W2-G4 and W2-G5. The trees within these groups have probably had their growth stunted by a combination of the saturated soil, prevailing winds and salt spray.

6.6. Govetts Copse (W3)

This 0.40 hectare woodland adjoins agricultural pasture to the west, east and south and it adjoins the public footpath to the north. It contains mainly Ash, with some Field Maple and English Oak. The understorey is typically Thorn and Blackthorn with Elder. The trees are mainly in fair or good condition although some of the taller trees (T 4 to 7) are showing signs of windthrow and should be inspected before working close to them.

6.7. Haysgrove Brake (W8)

This 0.9 hectare woodland is surrounded by agricultural pasture to the east and south and by water course and ditches to the north and west. There are remains of woodland embankments surrounding the woodland, however some of these are no longer the boundary given additional planting. A large section is the east of the woodland has been removed to allow Badger mitigation works. These works have exposed the remaining mature Field Maples, Hawthorn and English Elm, however given the low height of the trees and the prevailing wind is from the north-west there is not a significant increase in the risk of these trees failing due to windthrow. The areas of woodland in close proximity to the water course and the ditches can be considered as a wetwood. The majority of the woodland consists of the group W8-G2 in the southern and western sections of the wood. Approximately 30% of this group is dying or moribund and the other 70% is dead. It appears that these trees have been planted in last 10/20 years a few of the planted rows have been felled approximately 5/10 years ago. The growth of these trees have been limited due to the water logged soils, salt spray, high winds and Dutch Elm disease. There are a number of mature individual Field Maple, Oak, Hawthorn, Crack Willow trees on the remaining eastern woodland embankment and within the north eastern section of the woodland. These trees provide the significant value to the landscape and wildlife and some of them have been identified as possible habitat for bats and birds.

6.8. Newclose Covert (W9)

This 0.35 hectare woodland has woodland embankments upon all of its boundaries which are surrounded by agricultural land. It consists principally of Ash and English Elm surrounded by a mixed hedge of Hawthorn, Field Maple, Blackthorn and Dogwood. Most of the trees are in poor physiological and structural condition.

6.9. Bishops Wood (WW)

This 2.8 hectare new native woodland has been planted on agricultural land in the last 5 years or so. The majority of the trees are still tied and staked within their tree guards. There is no damage to the trees and none of the trees have a diameter greater than 150mm. The pheasant pen within the woodland, does not appear to have been used in the recent past.

6.10. Bum Brook, Shurton (A1)

A section of hedge that forms the southern boundary of the Company's ownership. That consists of a large Willow in poor condition and a group of Willows that have been pollarded.

6.11. Hedgerow Trees

A small number of the existing hedgerows within the site contain hedgerow trees. These hedges (Nos 36, 38, 49 and alongside Bum Brook) are marked on the plan.

7. TREE PROTECTION ZONE (TPZ)

The resulting Root Protection Area (RPA) and TPZ for the trees using the standard calculation within BS 5837 (2005) is considered inappropriate for the majority of the trees surveyed. All the trees within the woodland areas could be considered as open grown trees and therefore up to 20% of their RPA can be offset in one direction.

The formation of a lynchet around the trees within the woodland embankments will also have restricted the ability of tree roots to establish and develop within the fields. The trees in close proximity to the water course, and within waterlogged ground, will also have had their root growth inhibited due to the lack of oxygen and nutrients within these environments. Similarly, trees located adjoining established tracks and areas of hard standing will have had their root growth inhibited by these compacted substrates.

Tree protection fencing should take into account the existing landscape features. The fencing should be positioned on the far side of areas of hardstanding, to prevent access beneath the branch spread of the adjacent trees. The fencing within the fields should be positioned outside the widest branch spread, or to five metres, whichever is the greater distance.

8. CONCLUSION

The submission of this report, combined with the previous report (*(Adas, 2010) Tree Survey Hinkley Point C Development Site*) completes the survey for all the principal groups of trees within the proposed development site.

Tree Protection Zones (TPZ) should be installed around all trees that will be retained. This should be installed prior to construction and maintained until all development works are complete. The recommended Protective Barrier construction shown in Figure 2 of BS 5837 (2005), should be adopted as a minimum standard.

It is recommended that all standing and / or collapsing trees, which could fail across the TPZ are removed, as these pose a risk to members of the public and the work force.

TPZ are not required around those trees or groups which are to be removed as part an approved planning application; unless specifically requested as part of planning conditions.

Mitigation planting should be taken into consideration where trees and woodlands are proposed to be removed. This mitigation should aim to replace like for like; however the use of English elm should be avoided, due to the poor health of the trees within the current woodlands.

TREE CATEGORIES

Category A
Those of high quality and value: in such a condition as to be able to make a substatial contribution (a minimum of 40 years is suggested).

Category B
Those of moderate quality and value: those in such a condition as to make a significant contribution (a minimum of 20 years is suggested).

Category C
Those of low quality and value: currently in adequate condition to remain until new planting could be established (a minimum of 10 years is suggested), or young trees with a stem diameter below 150mm.

Category R
Those in such a condition that any existing value would be lost within 10 years and which should, in the current context, be removed for reasons of sound arboricultural management.

Offsite Tree

Recommended 'Root Protection Area' (RPA) of trees proposed for retention calculated using the method set out in para 5.2.2 of BS5837:2005.

APPENDIX 3 – BS 5837 – TREE CATEGORY GRADING

See following page.

Table 1 — Cascade chart for tree quality assessment

TREES FOR REMOVAL

Category and definition	Criteria	Identification on plan
<u>Category R</u> Those in such a condition that any existing value would be lost within 10 years and which should, in the current context, be removed for reasons of sound arboricultural management	• Trees that have a serious, irremediable, structural defect, such that their early loss is expected due to collapse, including those that will become unviable after removal of other R category trees (i.e. where, for whatever reason, the loss of companion shelter cannot be mitigated by pruning) • Trees that are dead or are showing signs of significant, immediate, and irreversible overall decline • Trees infected with pathogens of significance to the health and/or safety of other trees nearby (e.g. Dutch elm disease), or very low quality trees suppressing adjacent trees of better quality NOTE Habitat reinstatement may be appropriate (e.g. R category tree used as a bat roost: installation of bat box in nearby tree).	DARK RED

TREES TO BE CONSIDERED FOR RETENTION

Category and definition	Criteria — Subcategories			Identification on plan
	1 Mainly arboricultural values	2 Mainly landscape values	3 Mainly cultural values, including conservation	
<u>Category A</u> **Those of high quality and value:** in such a condition as to be able to make a substantial contribution (a minimum of 40 years is suggested)	Trees that are particularly good examples of their species, especially if rare or unusual, or essential components of groups, or of formal or semi-formal arboricultural features (e.g. the dominant and/or principal trees within an avenue)	Trees, groups or woodlands which provide a definite screening or softening effect to the locality in relation to views into or out of the site, or those of particular visual importance (e.g. avenues or other arboricultural features assessed as groups)	Trees, groups or woodlands of significant conservation, historical, commemorative or other value (e.g. veteran trees or wood-pasture)	LIGHT GREEN
<u>Category B</u> **Those of moderate quality and value:** those in such a condition as to make a significant contribution (a minimum of 20 years is suggested)	Trees that might be included in the high category, but are downgraded because of impaired condition (e.g. presence of remediable defects including unsympathetic past management and minor storm damage)	Trees present in numbers, usually as groups or woodlands, such that they form distinct landscape features, thereby attracting a higher collective rating than they might as individuals but which are not, individually, essential components of formal or semi-formal arboricultural features (e.g. trees of moderate quality within an avenue that includes better, A category specimens), or trees situated mainly internally to the site, therefore individually having little visual impact on the wider locality	Trees with clearly identifiable conservation or other cultural benefits	MID BLUE
<u>Category C</u> **Those of low quality and value:** currently in adequate condition to remain until new planting could be established (a minimum of 10 years is suggested), or young trees with a stem diameter below 150 mm	Trees not qualifying in higher categories NOTE Whilst C category trees will usually not be retained where they would impose a significant constraint on development, young trees with a stem diameter of less than 150 mm should be considered for relocation.	Trees present in groups or woodlands, but without this conferring on them significantly greater landscape value, and/or trees offering low or only temporary screening benefit	Trees with very limited conservation or other cultural benefits	GREY

Tree Survey
Hinkley Point C Development Site
Hinkley Point Nuclear Power Station, Somerset

Report by: Ian Braddock BSc (Hons) Arb
Checked by: Jon Abbatt MICFor & William Little

Date: July 2010

CONTENTS

1. INTRODUCTION

This report was commissioned by Judith Linnane of EDF Energy on 16th June 2010 and concerns vegetation along the west of Wick Moor Drove, the north and south of Green Lane, and the east of Benhole Lane, all of which are either within the site or border the site of the proposed development of a new nuclear power station known as Hinkley Point C, at the existing Hinkley Point Nuclear Power Station in Somerset on the Severn Estuary.

The report provides a survey of trees, and other landscape features such as hedges, closely following the guidance provided in British Standard (BS) 5837 (2005) 'Trees in Relation to Construction – Recommendations'.

2. LIMITATIONS

A topographical survey of the area, identifying trees and other landscape features, was not available at the time of the survey. Consequently, the positions of the features identified on the Tree Survey Plan have been plotted by the combination of aerial photography, GPS, and by eye. Accuracy is sufficient to enable identification of features on site; the buffer zones should be measured and laid out on site using original land survey data.

Only those features that were immediately parallel with Wick Moor Drove, Green Lane and Benhole Lane have been surveyed; such hedges that are perpendicular to these lanes have not been recorded.

Similarly, only features that were apparent at the time of inspection could be considered and no liability can be accepted regarding trees, hedges or their parts that were inaccessible or obscured in part or in whole.

Whilst hedges have been identified, only general information has been recorded for these features. Their quality grading system within BS 5837 (2005) is not appropriate for hedges, and therefore such features have not been assigned a grade. The quality of a hedge would need to be done as part of a specific hedgerow survey, following the requirements of The Hedgerow Regulations 1997.

3. SURVEY METHODOLOGY

The survey was carried out by Ian Braddock of ADAS between the 5th and 7th July 2010.

The survey consisted of an inspection of the vegetation along the western side of Wick Moor Drove (the southern extent is approximately 100m north of the junction with North Lane; and the northern extent is adjacent to the car park within the power station's boundary fence), the north and south sides of Green Lane (between Wick Moor Drove to the east and Benhole Lane to the west), and the eastern side of Benhole Lane (the northern extent is approximately 400m north of the junction of Green Lane and Benhole Lane, where it fades into a field entrance; and the southern extent is approximately 680m north of its junction with the main road through Shurton). These can be seen on the Tree Survey Plan overview attached at Appendix 1.

Following the guidance provided in BS 5837 (2005), the survey has identified individual trees, groups of trees, woodlands, and hedges which would ordinarily have been included on a topographical survey.

The vegetation was inspected from ground level, by eye.

The weather conditions were generally dry and bright, with good visibility.

All height measurements were taken using a TruPulse laser where there was clear visibility of the stem, base and top of the feature to be measured. Where this was not possible, height measurements were estimated.

The stem diameters of single stem trees were taken at 1.5m above ground level, or just above the root flare for multi-stemmed trees. Where trees were not easily accessible the diameters have been estimated; and for group of trees the largest stem diameter within the group has been recorded.

The survey recorded the following information for each tree or group of trees:

Tree No.	-	Individual Tree (T); Group of Trees (G); Hedge (H); Woodland (W).
Species	-	Common and Latin Name of Tree(s);
Stem Count	-	The approximate number of trees within a group (if applicable).
Single or Multiple Stem	-	'S' represents a tree which has a single clear stemto at least 1.5m above ground level, whilst 'M' represents a tree where the main stem divides into at least two stems below 1.5m above ground level.
Height	-	Measured from the adjacent ground level in metres;
Stem Diameter	-	Measured at 1.5m above ground level, or immediately above the root flare for multi-stemmed trees and recorded in millimetres;
Crown Spread	-	Measured in metres to the four cardinal points (north, south, east and west);
Height of Crown Clearance	-	The clearance between the adjacent ground level and the crown of the tree, measured in metres;

Age Class	-	The stage at which the tree, or majority within a group, is in its life cycle (**Y**oung. **M**iddle –**A**ged, **M**ature may be prefixed with 'E' Early or 'L' Late **O**ver –**M**ature, or **V**eteran)
Physiological Condition	-	Its characteristics to normal functioning (Good, Fair, Poor or Dead);
Structural Condition	-	Any physical defects or abnormalities noted;
Preliminary Management Recommendations	-	Any necessary management work prior to development;
Estimated Remaining	-	An estimation of how long the tree(s) or hedge
Contribution	-	will successfully contribute to its surroundings in years (<10, 10-20, 20-40, 40+);
Category Grading	-	The overall quality of the tree(s), sub-fixed with its main value: **R** = Removal, **A** = High quality, **B** = Medium quality, **C** = Low quality and **1** = Arboricultural value, **2** = Landscape value, **3** = Cultural value.
Root Protection Area	-	Given as a radius in metres from the stem of the tree (or the edge tree of a group or stem of a hedge) [on the Tree Survey plan this may be extended to protect the spread of the crown].

5. DISCUSSION

5.1. General

Much of the site is exposed to the prevailing north-westerly winds, consequently many of the individual and groups of trees have adopted uncharacteristically small canopy spreads to the north and west, yet have compensated this by developing larger canopy spreads generally to the east.

5.2. West Moor Drove

This can be taken in two distinct sections; the first section from north of the junction with North Lane up to the power station main gates, and the second from the main gates up to the main car park south of the Site Induction & Training suite.

The first section is mainly rural roadside hedge with occasional hedgerow trees, and a prominent group of white willow mid section; whilst the second section is more formal hedge and tree planting.

The hedges within both sections were generally species rich. In the first section, where hedge management has taken place this has generally been limited to their western sides where they border arable fields. The hedgerow trees are probably outgrown hedge stock and are generally young to early mature, and as such do not provide a substantial or significant contribution to the local treescape. The exception to this would be the group of mature white willows (G2), but due to their brittle nature and heavy lean over the road, they are unlikely to provide a contribution to the area much past a further 10 years, which in turn limits the grading that can be afforded to them.

The hedges in the second section are regularly trimmed creating a formal box shape. The trees to the rear of these hedges are generally common ash (*Fraxinus excelsior*) and were probably originally planted as 'specimen' trees, but due to the strong prevailing winds have developed poor form; some of which are also suffering badly with tumerous cankers (*Pseudomonas syringae* subsp. s*avastonoi* pv. *fraxini*). This has subsequently affected the quality grading that could be afforded to these trees.

5.3. Green Lane

The majority of the vegetation along Green Lane is situated to its south; the exception being one hedge on the north side, towards the eastern end with Wick Moor Drove.

The hedges along Green Lane are generally species rich, similar to those along Wick Moor Drove.

A significant proportion of the vegetation along Green Lane consists of stands of outgrown English elm (*Ulmus procera*), which is either the cumulative years of regeneration from historic stumps of elm trees prior to the outbreak of Dutch Elm Disease, or possibly the development and maturing of unmanaged hedgerow stock. Unfortunately a significant number of these stems have more recently succumbed to Dutch Elm Disease, and are now standing and/or collapsing dead stems. It is also unfortunate that is highly likely that the remaining stems will too succumb to the same disease in the not too distant future.

5.4. Benhole Lane

The section of Benhole Lane north of Green Lane is largely open to arable fields on the west, and to the east it is bordered again by species rich hedge, with groups of collapsing elm stems.

To the south of a derelict barn along the northern section of Benhole Lane, on the western side, on the north of a field drain is a moderate size multi-stem white willow, regenerating from a single fallen stem historically cut just above ground level. Given its relatively sheltered location it has a fairly even canopy spread.

The southern section of Benhole Lane, beyond Green Lane, consists of mature species rich hedges on both sides. There are also groups of outgrown English elms, probably originating from similar sources to that described for the elms along Green Lane. These too are also succumbing to Dutch Elm Disease, which in turn is creating standing and/or collapsing dead trees.

Towards the southern extent of Benhole Lane is, what has been recorded as, a mature to over-mature woodland (W1 on the Tree Survey Plan), despite the lack of ground flora; and it is in fair to poor condition. The woodland contains an over-mature ash (*Fraxinus excelsior*), which is the largest of the trees surveyed across the site, in terms of stem diameter and canopy spread (up to 8m over the eastern field boundaries). Unconfirmed badger setts were also prevalent throughout this area of woodland.

Ash continued to dominate the hedgerows in the southern section of Benhole Lane, as well as beyond the boundary limits of this survey; albeit not quite as large trees as the one within the woodland.

6. TREE PROTECTION

ADAS have been advised that buffer zones, which will be exclusion zones to construction and storage, will be positioned along the west of Wick Moor Drove, the north and south of Green Lane, and to the majority of the east side of Benhole Lane. It is also understood that these buffer zones will be a minimum of 7m along Wick Moor Drove, 15m on the north and south of Green Lane, and 30m along Benhole Lane.

As none of the root protection areas, or canopy spreads, of the trees or landscape features surveyed extend beyond these buffer zones, it is highly unlikely that any damage to retained trees or features will occur.

As a minimum the buffer zones should be maintained, prior and until all development works are complete, by use of the recommended Protective Barrier construction shown in Figure 2 of BS 5837 (2005); an extract of this illustration has been attached to Appendix 2.

7. CONCLUSION

Given the proposed buffer zones along Wick Moor Drove, Green Lane and the majority of Benhole Lane, it is highly unlikely that any retained tree or landscape feature will be affected by the proposed development. Should these zones be removed or amended, then the risk to retained trees and/or landscape features should be re-assessed by an arboriculturist.

The buffer zones should be maintained, prior and until all development works are complete, by use of the recommended Protective Barrier construction shown in Figure 2 of BS 5837 (2005), as a minimum standard; an extract of this illustration has been attached to Appendix 2.

The removal of dead standing and/or collapsing elm stems along Wick Moor Drove is advisable prior to development work commencing; as these could fail beyond the buffer zones.

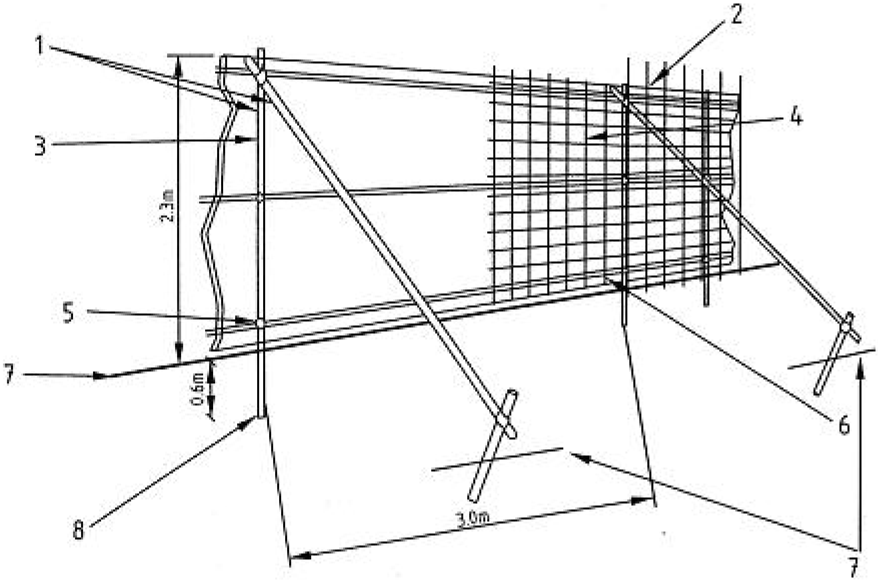
APPENDIX 2 – PROTECTIVE BARRIER ILLUSTRATION

See following page.



1 Standard scaffold poles

2 Uprights to be driven into the ground

3 Panels secured to uprights with wire ties and where necessary standard scaffold clamps

4 Weldmesh wired to the uprights and horizontals

5 Standard clamps

6 Wire twisted and secured on inside face of fencing to avoid easy dismantling

7 Ground level

8 Approx. 0.6 m driven into the ground

26	ST 1995 4595	Hollow in field 2	Undated	Unknown	Monument
27	ST 2005 4605	Linear earthwork in field 2	Undated	Unknown	Monument
28	ST 197 459	Pond in field 4	Undated	Pond/quarry	Monument
29	ST 2000 4590	Hollow in field 6	Undated	Pond/quarry	Monument
30	ST 2025 4595	Uneven ground/differential plant growth in field 6	Undated	Unknown	Monument
31	ST 202 458	Small stone bridge between fields over drainage ditch between fields 6 and 10	Undated	Bridge	Monument
32	ST 2025 4570	Field boundary in field 10	Undated	Field boundary	Monument
33	ST 2030 4570	Field boundary in field 10	Undated	Field boundary	Monument
34	ST 208 454	Penannular differential crop growth c.15m radius with slight mound in field 16.	Undated	Unknown	Monument
35	ST 204 456	Linear and curvilinear features, possible enclosure	Undated	Unknown	Monument
36	ST 199 455	Building in field shown on 1614 map	Medieval/ Post-Medieval	Building	Monument

ID Number	National Grid Reference	Description	Period	Monument Type	Record Type
37	ST 225 465 ST 234 470 ST 238 461	Submarine forest and peat deposits, Stolford shore, Stogursey	Mesolithic to Bronze Age	Forest	Monument
38	ST 1985 4485	Scatter of possible tesserae in field 26	Roman?	Mosaic?	Find Spot
39	ST 219 458	Ridge and furrow, Wick Moor, Stolford	medieval	Ridge and Furrow	Monument
40	ST 21250 44620	Shrunken village, Wick	medieval	Settlement	Monument
41	ST 2045 4500	Remains of North Lane. Very wide ditch (c 4 m wide) at northern section of field boundary in Field 29 with Field 28. A dip in field 25 probably rerpresents a continuation of the lane northwards.	medieval?/Post-medieval	Road?	Monument
42	ST 2015 4428	Thatch End with bridge over stream at entrance to South East Wing (Thatch End prevously listed), Shurton, Grade II Listed	Post-medieval	Listed Building	Listed Building
43	ST 2014 4427	Foot bridge, 5 metres south west of Thatch End, Shurton, Stogursey, Grade II Listed	Post-medieval	Listed Building	Listed Building
44	ST 2009 4417	Fishers and Brookside, Shurton, Stogursey, Grade II Listed	Post-medieval	Listed Building	Listed Building
45	ST 2004 4410	Shurton Lodge and outbuilding attached at South East corner, Shurton, Stogursey, Grade II Listed	Post-medieval	Listed Building	Listed Building
46	ST 2003 4412	Cottage, 15 metres North of Shurton Lodge, Shurton, Grade II Listed	Post-medieval	Listed Building	Listed Building
47	ST 1997 4420	Shurton Court and No.2 Shurton Court (Shurton Court previously listed), Shurton, Grade II Listed	Post-medieval	Listed Building	Listed Building
48	ST 1996 4402	Ash Cottage and Little Ash, Shurton, Grade II Listed	Post-medieval	Listed Building	Listed Building
49	ST 2063 4404	Shurton Mills, Shurton, Grade II Listed	Post-medieval	Listed Building	Listed Building
50	ST 20410 44610	Deserted farm, Corner, N of Shurton. Differential crop growth in southern part of field 28 with adjacent pile of rubble are almost certainly remains of this site and its associated enclosures.	Post-medieval	Farmstead	Monument
51	ST 2209 4596	Groynes, E of Hinkley Point	Post-medieval	Groyne	Monument
52	ST 193 444	Knighton Farmhouse, Burton	Post-medieval	Farmhouse	Monument

ID Number	National Grid Reference	Description	Period	Monument Type	Record Type
53	ST 20401 44569	Short stretch of stone wall built along north stream bank to prevent undercutting at southern boundary of Field 28.	Post-medieval	Wall	Monument
54	ST 20644 45709	Indistinct earthworks in centre of field 34. Possibly remains of accomodation block/camp from construction of power station in 1970s	Post-medieval	Settlement?	Monument
55	ST 20594 45064	Dip in Field 25 probably represents a lost field boundary	Post-medieval	Earthwork	Monument
56	ST 20194 45158	Canalised stream running through Fields 17-20 and between Fields 21 and 22.	Post-medieval	Drainage Channel	Monument
57	ST 20764 45813	Two banks in area of woodland (Field 36) running north-south and east-west each approximately 0.7 m high.	Post-medieval	Field boundary?	Monument
58	ST 2170 4594	Enclosure, Wick Moor, Stogursey	Undated	Enclosure	Monument
59	ST 20032 44898	Hollow, possible pond, between fields 18 and 27	Undated	Pond?	Monument
60	ST 19891 44960	Earthworks in northern half of Field 18. Some of these are historical field boundaries recorded on the 1841 tithe map, and others may be earlier field boundaries.	Undated	Field boundary?	Monument
61	ST 20204 45219	Low bank running east-west along southern side of field boundary between fields 13 to 15 and Fields 17 to 21.	Undated	Unknown	Monument

1 INTRODUCTION

1.1 Background

1.1.1 EDF Energy, in its assessment of the requirements for Nuclear New Build at Hinkley Point, requires quantitative baseline data with regard to the recreational access and use of Public Rights of Way (PRoW) around the Hinkley area, in order to adequately identify the baseline and assess the scale and significance of the impacts of the proposed development.

1.1.2 Royal Haskoning have been commissioned to undertake a recreational access survey around the Hinkley area, to provide quantitative baseline data to inform the Environmental Impact Assessment (EIA) for the proposed new nuclear development at Hinkley Point. The data in the final recreational access report will be incorporated into the Hinkley C Environmental Statement (ES).

1.1.3 The aim of the survey is to collect survey data on recreational use, including frequency and type of activity, along the footpath / track network around Hinkley Point, as well as to gain an understanding of the condition of the footpath network around the study area.

1.1.4 This report presents the full survey results and analysis of recreational access as well as condition of the footpath network.

1.2 Methodology

1.2.1 The recreational access survey method is based on the following survey tasks and breakdown:

1. 1 hour counts at a number of discrete access points and locations across the path network (focusing on footpath intersections).
2. Survey of 12 locations (see **Figure 1.1**). The spread of counts at each survey location for different survey days are presented in **Table 1.1**.
3. Surveying during daylight hours between the times of 07:00 and 19:00.
4. Surveying carried out at all points during and after the school holidays, and at all sites on a weekday as well as on a weekend. Each survey location to be counted at least 4 times over the overall survey.
5. Surveys to be staggered so that survey days do not take place in consecutive days, but all survey locations to be counted on each day when survey takes place.
6. A questionnaire aimed at identifying the recreational use (both of the footpaths in the area and around the larger area) to be undertaken of any footpath users during the counts.

Table 1.1 Proposed Count Locations and Times

Time \ Date	Holiday Weekday	Holiday Weekend	Term Weekday	Term Weekend
07:00 – 08:00	Site 1	Site 8	Site 12	Site 4
08:00 – 09:00	Site 2	Site 9	Site 1	Site 5
09:00 – 10:00	Site 3	Site 10	Site 2	Site 6
10:00 – 11:00	Site 4	Site 11	Site 3	Site 7
11:00 – 12:00	Site 5	Site 12	Site 4	Site 8
12:00 – 13:00	Site 6	Site 1	Site 5	Site 9
13:00 – 14:00	Site 7	Site 2	Site 6	Site 10
14:00 – 15:00	Site 8	Site 3	Site 7	Site 11
15:00 – 16:00	Site 9	Site 4	Site 8	Site 12
16:00 – 17:00	Site 10	Site 5	Site 9	Site 1
17:00 – 18:00	Site 11	Site 6	Site 10	Site 2
18:00 – 19:00	Site 12	Site 7	Site 11	Site 3

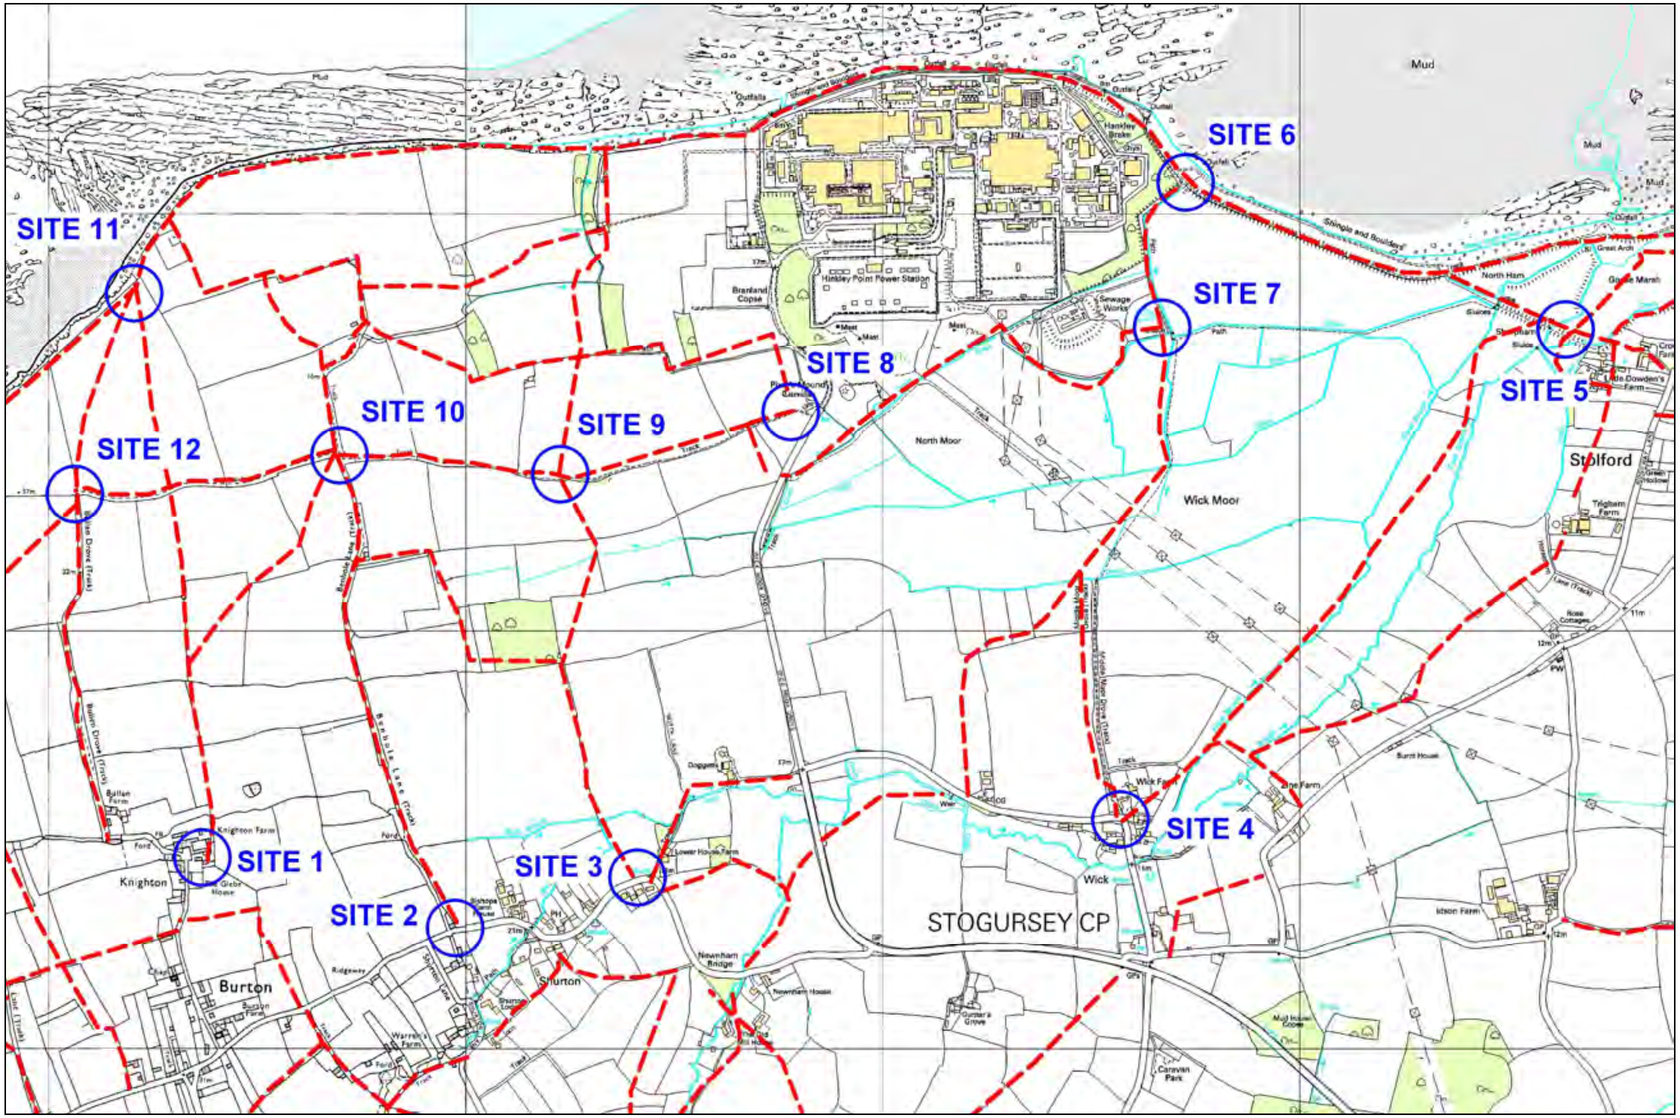
1.2.2 A wide variety of information was recorded during the surveys, including:

1. At access points, surveyors noted whether people arrived by vehicle or on foot, as well as numbers and typical age range.
2. Surveyors recorded if any of the people left the paths.
3. Recreational activity type (i.e. walking, dog-walking, cycling, horse-riding, going fishing, etc).
4. Surveyors recorded whether the same users pass the opposite way at each survey location (in order to determine whether people use differing routes during access and egress).
5. Description and photographs of the survey points, as well as the footpath/track to each survey point, noting condition (overgrown, well maintained, muddy, etc), type of route (mud, gravel, paved, tarmac, concrete).
6. For each survey the weather conditions were recorded.
7. The questionnaire was directed at recreational participants only, and focussed on gaining an understanding of the frequency and extent of use of the footpath network.

1.3 Structure of this Report

1.3.1 The first section of this report introduces the reason for the survey, whilst **Section 2** presents the questionnaire and survey recording. **Section 3** presents the details of the surveys undertaken, and **Section 4** presents the results, with a discussion of the results presented in **Section 5**. **Section 6** presents the results of the footpath condition survey.

Figure 1.1 Survey Locations



2 SURVEY RECORDING AND QUESTIONNAIRE

2.1 Introduction

2.1.1 This section sets out the approach and methodology for the footpath survey, counts of footpath users and the use of the survey questionnaire.

2.2 Questionnaire

2.2.1 A questionnaire was devised in order to gain information about the use of the footpaths, particularly information on where people originated from, how often they use the footpaths in the study area, what they use the footpaths for, their ideas of what makes a good footpath, and additional social data to put the study area and the footpath uses into context. The questionnaire devised was submitted to Somerset County Council for comment, though no changes were identified. The questionnaire is presented in **Appendix A**.

2.3 Footpath Counts

2.3.1 In order to count the number of users of the footpaths and survey locations, a referencing system was devised which comprised a site number and footpath reference number, as shown in **Figure 2.1**.

2.3.2 Recording sheets were created to ensure that the counts were structured and the results formally recorded (a copy of the sheet is provided at **Appendix B**). The sheets were used to record the number of users along each footpath length where visible on the ground, so that an indication of the overall use of each length of footpath could be determined.

2.4 Footpath Survey

2.4.1 As well as counting users, the footpaths within the study area are also assessed to gain an understanding of their condition and 'value' in the wider sense. In order to ensure a formal and standardised recording of the various features associated with each length of footpath, a proforma was generated and used (see example at **Appendix C**).

3 RECREATIONAL ACCESS SURVEY

3.1 Introduction

3.1.1 This section presents the details of the surveys undertaken in relation to recreational access use and quantification for the Hinkley Point study area.

3.2 Survey Details

3.2.1 Surveys were carried out in term time and during the summer holiday period, on the following dates:

- Wednesday 15th July 2009;
- Saturday 18th July 2009;
- Wednesday 26th August 2009; and
- Sunday 30th August 2009.

3.2.2 All surveys started at 07:00 and continued until 19:00.

3.2.3 The survey on the 15th July 2009 was carried out by A Chalmers (Lead Surveyor) and K Hillyer (Surveyor). The survey started at Site 1, and then on each hour, the survey moved on to the subsequent site (i.e. Site 2, then Site 3, then Site 4, and on to Site 12). Starting at Site 1 does not link with the commencement site (12) identified in **Table 1.1**, however, this does not affect the survey findings in any way.

3.2.4 The survey on the 18th July 2009 was carried out by P Thornton (Lead Surveyor) and A Chalmers (Surveyor). The survey started at Site 4, and then on each hour, the survey moved on to the subsequent site (i.e. Site 5, then Site 6, then Site 7, and on to Site 12, after which the next site was Site 1).

3.2.5 The survey on the 26th August 2009 was carried out by A Chalmers (Lead Surveyor) and K Hillyer (Surveyor). The survey started at Site 8, after which on each hour the survey moved on the subsequent site (i.e. Site 9, then Site 10, then Site 11, then Site 12, then Site 1, etc.).

3.2.6 The survey on the 30th August 2009 was carried out by P Thornton (Lead Surveyor) and A Chalmers (Surveyor). The survey started at Site 12, and then on each hour, the survey moved on to the subsequent site (i.e. Site 5, then Site 6, then Site 7, and on to Site 12, after which the next site was be Site 1).

3.2.7 A circular route for the survey locations was undertaken so that the distance to the survey vehicle was not excessive at the end of the day.

3.2.8 In order for the counts to commence at each site on the hour, one of the surveyors would depart to the next site with sufficient time to reach it by the start of the survey period. The remaining surveyor stayed at the former survey site until the hour was reached, at which point they would then depart to the next site to meet up with the other surveyor.

3.3 Survey on the 15th July 2009

3.3.1 The weather on the 15th July 2009 consisted generally of broken cloud, with some sunny spells. The temperature was initially cool becoming warmer as the day progressed, and as cloud cleared in the afternoon. Generally the ground was dry, but puddles from rainfall the day before were evident at some locations. During the survey it was dry, with the exception of some light showers around lunchtime. Wind was calm in the morning but generally breezy throughout the day, though it was windier on the coastal sites to the west of Hinkley Point.

3.3.2 All sites were visited, and all survey counts were undertaken as planned. However, visitor and user numbers were generally low. The footpath count record sheets for this survey are presented in **Appendix D**, whilst the questionnaires that were undertaken are presented in **Appendix E**.

3.4 Survey on the 18th July 2009

3.4.1 The weather on the 18th July 2009 was overcast for most of the day until late afternoon/early evening when the cloud rapidly cleared and temperatures rose. The ground was dry or damp, with puddles from rainfall the day before present at some locations. During the survey it was dry, with the exception of some very light and short showers scattered through the day. Wind was breezy throughout the day, until late afternoon when the wind dropped.

3.4.2 All sites were visited and all survey counts were undertaken as planned, with the exception of Site 2. During the footpath survey it was identified that access along footpath F07 was closed to pedestrians due to an extremely large body of standing water across the path. Consequently, after 20 minutes, the surveyors moved to Site 3, and continued for 90 minutes at Site 3. Visitor and user numbers were generally low. The footpath count record sheets for this survey are presented in **Appendix F**, whilst the questionnaires that were undertaken are presented in **Appendix G**.

3.5 Survey on the 26th August 2009

3.5.1 The weather on the 26th August 2009 was damp and overcast, though dry early in the morning. Showers and persistent rain continued from mid morning and throughout most of the day. The temperature was cool throughout the day with little if any warming during the day. The ground was damp, with puddles present at many locations. During the survey it was predominantly wet and showery, with a strong breeze throughout the day.

3.5.2 All sites were visited with the exception of Site 2. Access along footpath F07 was closed to pedestrians due to localised flooding in the field and across the path. Consequently, an additional 1 hour of survey was undertaken at Site 1, and the survey then leapfrogged Site 2 to commence at Site 3. Visitor and user numbers were low, most likely due to the poor weather. The footpath count record sheets for this survey are presented in **Appendix H**, whilst the questionnaires that were undertaken are presented in **Appendix I**.

3.6 Survey on the 30th August 2009

3.6.1 The weather on the 30th August 2009 was overcast but dry in the morning. Though there were some short showers in the mid morning the rest of the day was dry but remained overcast. The temperature was cool throughout the day warming up slightly by early afternoon, but remaining cool in the wind. The ground was dry with only scattered puddles in damp locations. During the survey it was generally breezy, being windy at the exposed sites on the coastline.

3.6.2 All sites were visited with the exception of Site 2, due to the localised flooding (see previous comments). Consequently, an additional 1 hour of survey was undertaken at Site 12, and the survey then leapfrogged Site 2 to commence at Site 3. Visitor and user numbers were low, most likely due to the poor weather. The footpath count record sheets for this survey are presented in **Appendix J**, whilst the questionnaires that were undertaken are presented in **Appendix K**.

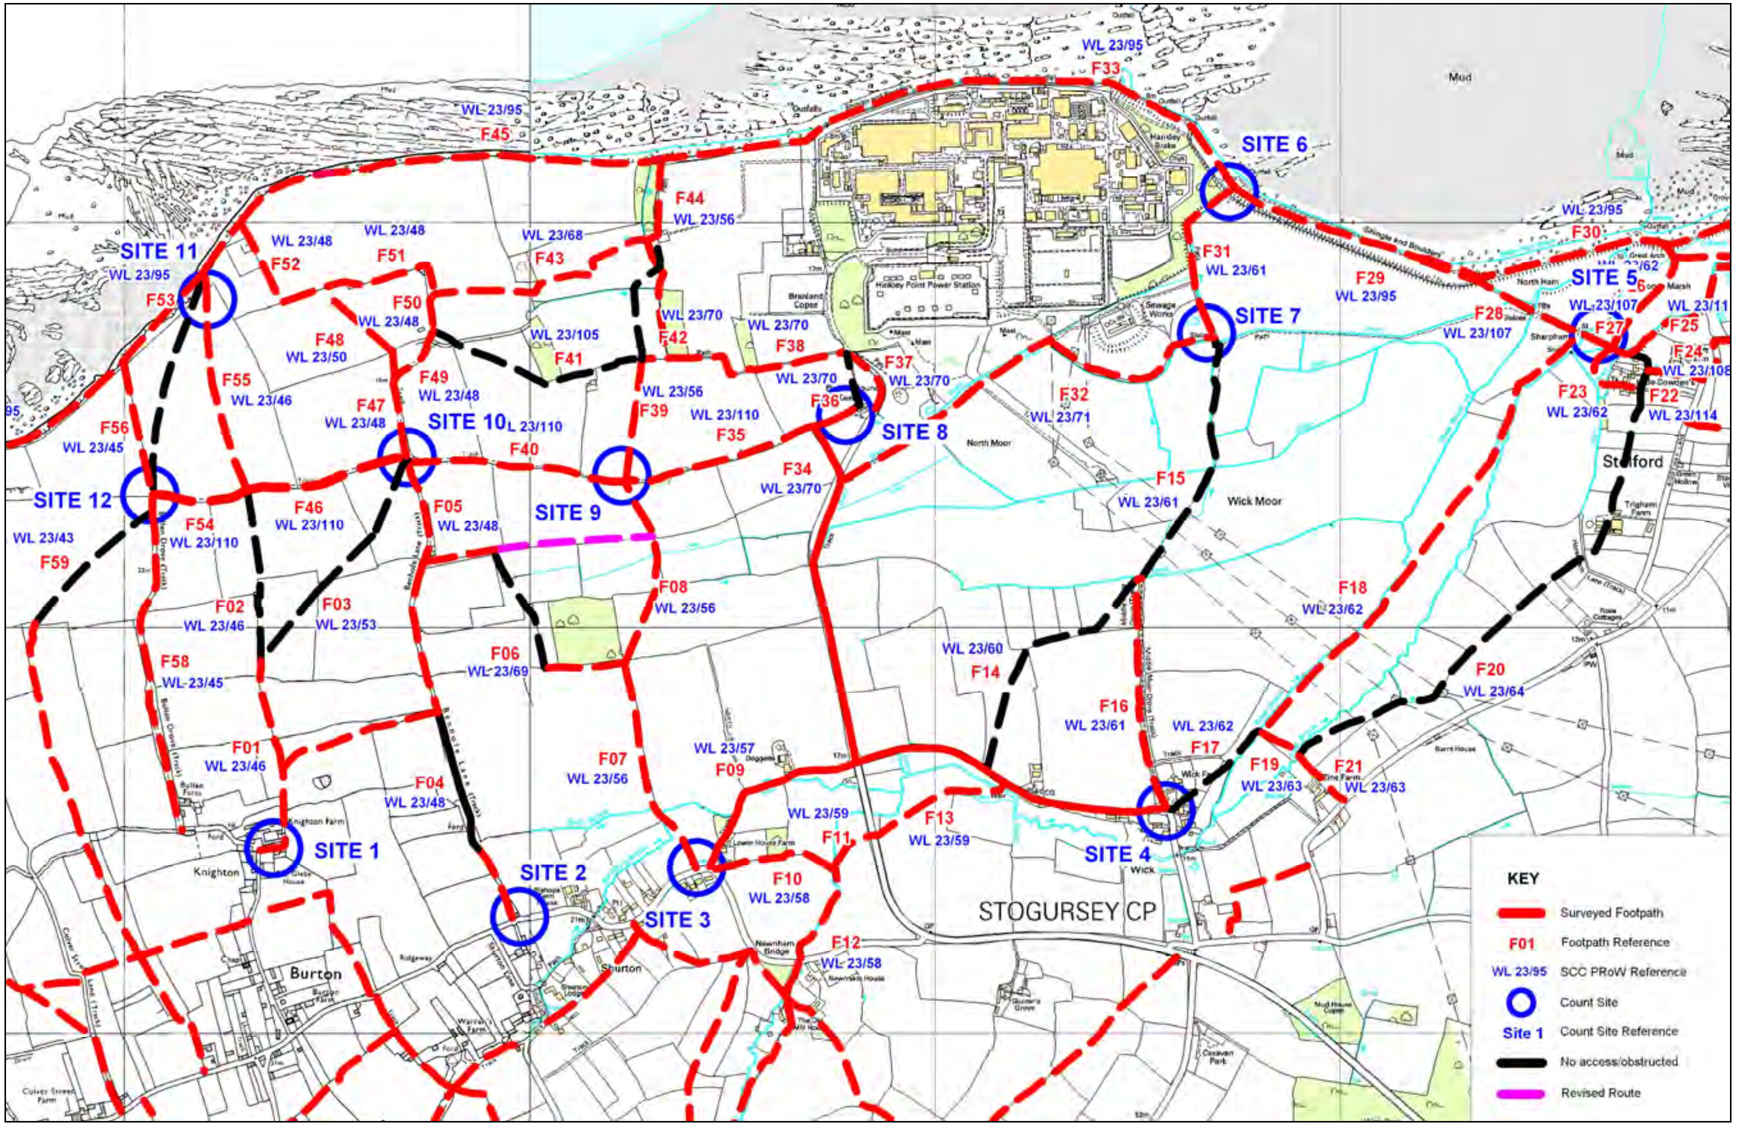
3.7 Footpath Condition Survey

3.7.1 The survey of footpath condition was undertaken on the 18th July 2009 and completed on the 30th August 2009. The completed record sheets are presented in **Appendix L**, whilst the photographs taken are presented in **Appendix M**.

3.7.2 During the survey on the 18th July, a number of footpath lengths were not surveyed, namely: F22 (WL 23/114), F24 (WL 23/108), F25 (WL 23/112), F30 (WL 23/95 partial), F34 (WL 23/70 partial), and F36 (WL 23/70 partial). These were surveyed on the 30th August 2009.

3.7.3 A number of footpaths had no visible access, or access was partially or completely obstructed. These footpaths were: F02 (WL 23/46 partial), F03 (WL 23/53 appears to divert east to join WL 23/48), F06 (partial), F14 (WL 23/60), F15 (WL 23/61 partial), F17 (WL 23/62 partial), F20 (WL 23/64 partial), F22 (WL 23/114), F41 (WL 23/105 partial), and F59 (WL 23/43 access/route not visible). **Figure 3.1** presents the footpaths surveyed, along with those that were obstructed or had been re-directed.

Figure 3.1 Footpaths Surveyed, and Footpaths Obstructed/Altered



4 RECREATIONAL ACCESS SURVEY RESULTS

4.1 Footpath Counts

4.1.1 On the survey date of the 15th July 2009, a total of 6 people were counted using the footpath network, shown on the results collated in **Appendix N**. Of these people, 2 were returning from fishing and the remaining 4 were dog walkers.

4.1.2 On the survey date of the 18th July 2009, a total of 7 people were counted using the footpath network, shown on the results collated in **Appendix O**. Of these people, 5 were dog walkers, one was visiting her cattle, and the remainder was a horse-rider.

4.1.3 On the survey date of the 26th August 2009, a total of 7 people were counted using the footpath network, shown on the results collated in **Appendix P**. Of these people, 6 were dog walkers, and one was walking alone.

4.1.4 On the survey date of the 30th August 2009, a total of 6 people were counted using the footpath network, shown on the results collated in **Appendix Q**. Of these people, 4 were dog walkers, and the remaining two were fishing along the coastal path.

4.2 Questionnaire Results

4.2.1 Of the total of 26 people counted using the footpath network, 20 completed the questionnaire individually or as a group, with a total of 15 completed questionnaire forms. The tabulated results of the questionnaires are presented in **Appendix R**.

4.3 Footpath Condition Survey Results

4.3.1 A number of footpaths had obstructed or no visible access, or access was partial due to obstructions. These footpaths were: F02 (WL 23/46), F03 (WL 23/53), F06 (WL 23/69), F14 (WL 23/60), F15 (WL 23/61), F17 (WL 23/62), F41 (WL 23/105), and F59 (WL 23/43). The detailed finding for each footpath is presented in **Appendix L** with photographs presented in **Appendix M**. The general findings are:

- No footpath was surfaced with tarmac, and the majority were not surfaced.
- Signposting was erratic, with the majority of footpath access not signposted.
- Where not obstructed, access was generally clear, with moderate to good conditions for the majority of gates, stiles, and watercourse crossings.
- Only one footpath was inaccessible due to cattle.
- The majority of footpaths were level, though a small number of relatively steep paths occur between the settlements of Burton, Shurton, and Stogursey, and the ridge to the north. These steep or sloping footpaths were often the most used.
- None of the footpaths surveyed had any lighting.
- The majority of footpaths were relatively tidy and accessible, with only a small number inaccessible due to vegetation growth.
- The majority of views (particularly to the west of the C182 Wick Moor Drove) were generally open and of distant landscape features such as Exmoor, the Quantocks, Brean Down/Bleadon Hills, the Severn Estuary, and Wales. More localised constrained views were predominantly found to the east of the C182 Wick Moor Drove, mainly due to the low-lying topography of the land.

5 DISCUSSION OF SURVEY RESULTS

5.1 Footpath Counts

5.1.1 **Table 5.1** summarises the total usage of the footpaths in the Hinkley Point area. The use of footpaths appears to be relatively low level, with use currently identified on footpath lengths F04 (WL 23/48), F05 (WL 23/48), F07 (WL 23/56), F08 (WL 23/56), F27 (WL 23/107), F28 (WL 23/107), F29 (WL 23/95), F33 (WL 23/95), F35 (WL 23/110), F39 (WL 23/56), F46 (WL 23/110), F53 (WL 23/95), F54 (WL 23/110), F55 (WL 23/46), F56 (WL 23/45), and F58 (WL 23/45). The origin of the footpath users appears to be Knighton, Shurton, Burton, Stogursey, and Stolford, based on the access points and likely destinations of the users. Furthermore, associated adjoining footpaths are also likely to be used as access to some of the paths presented in **Table 5.1** as they are linked by other footpaths. **Figure 5.1** shows the footpaths and includes coloured lines related to the number of counts on these lengths.

Table 5.1 Total Counts for each Footpath Length

5.1.2 Use appears to occur in 3 periods, early morning (around 07:00 to 09:00), lunchtime (around 12:00 to 14:00), and late afternoon to early evening (around 18:00 to 19:00). A graph showing the total counts over time is presented in **Figure 5.2**.

5.1.3 Ten out of the 20 people counted were individuals, whilst the remainder were in pairs.

Figure 5.1 Total Counts for Each Length of Footpath

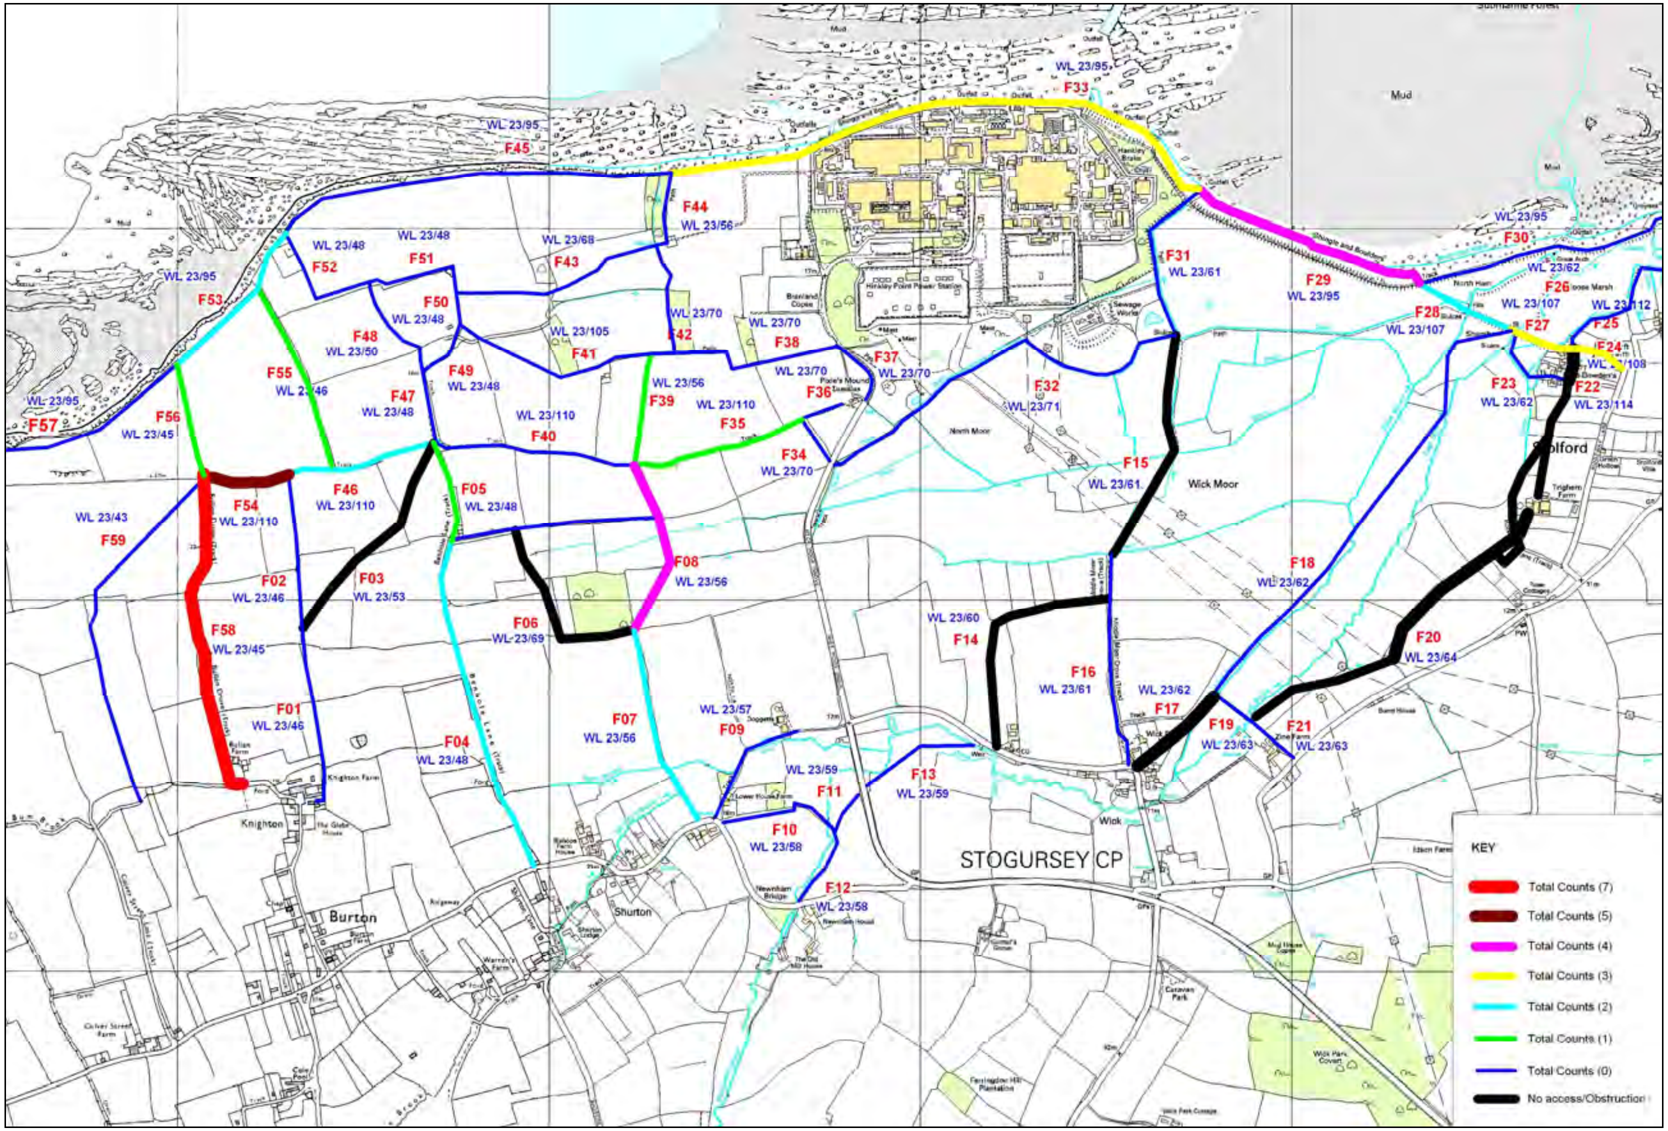

Figure 5.2 Total Counts Over Hourly Periods

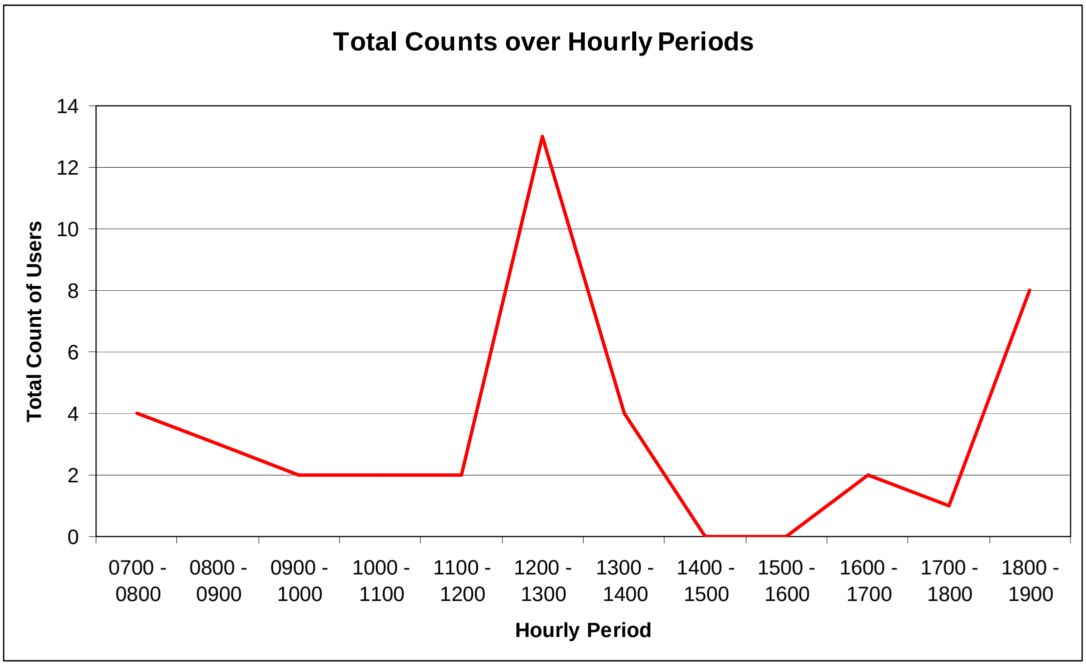
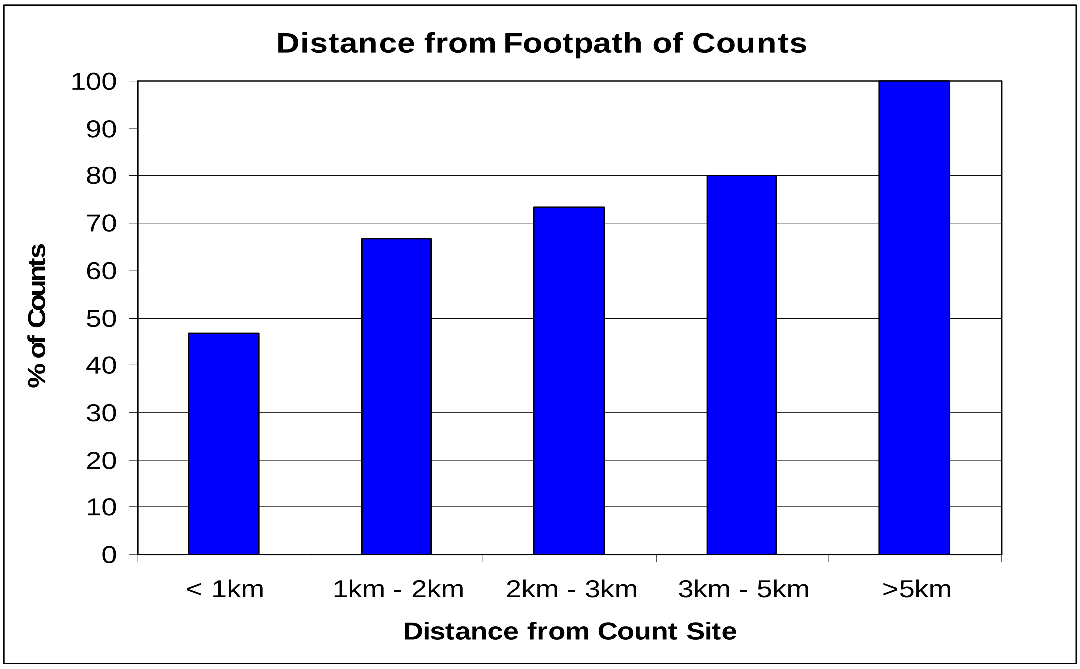


5.2 Questionnaire Findings

5.2.1 Initial findings of the questionnaire surveys are:

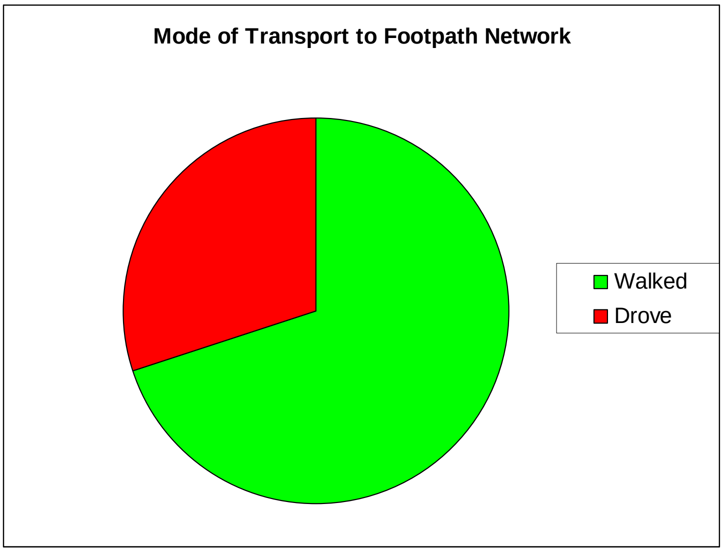
- The majority (70%) of users live in the Hinkley area, within less than 1 ½ miles from the footpath network, though this figure would be much less than a mile due to 2 visitors living outside the immediate study area. **Figure 5.3** is a graphical representation of residence distance from footpath;

Figure 5.3 Residence Distance from Footpath



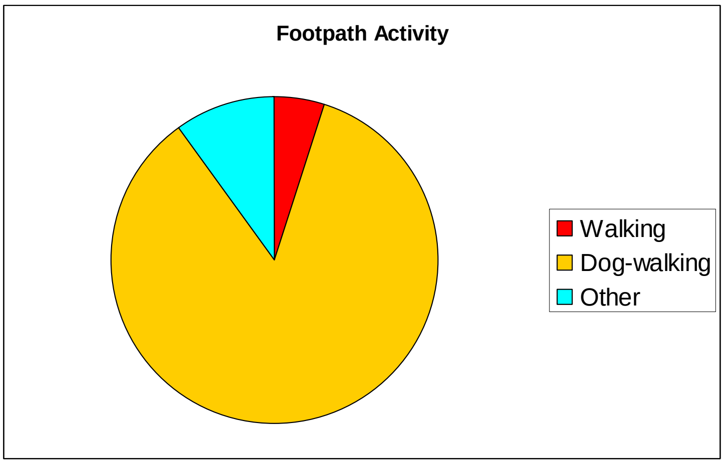
- A small number (30%) of users were from Bridgwater, Minehead or elsewhere;
- The majority (70%) of people walked to the footpath network from their place of residence, whilst the remainder drove and parked near a gate or within a farm, as presented in **Figure 5.4**;

Figure 5.4 Mode of Transport to Footpath Network



- 35% of users resided less than 5 minutes walking from the footpath network, and 75% within 30 minutes walking distance;
- Dog walkers were the most prolific users of the footpath network, with 85% of the surveyed people, with fishermen constituting 5%, and horse-riding and cattle owner comprising the remainder, as presented in **Figure 5.5**;

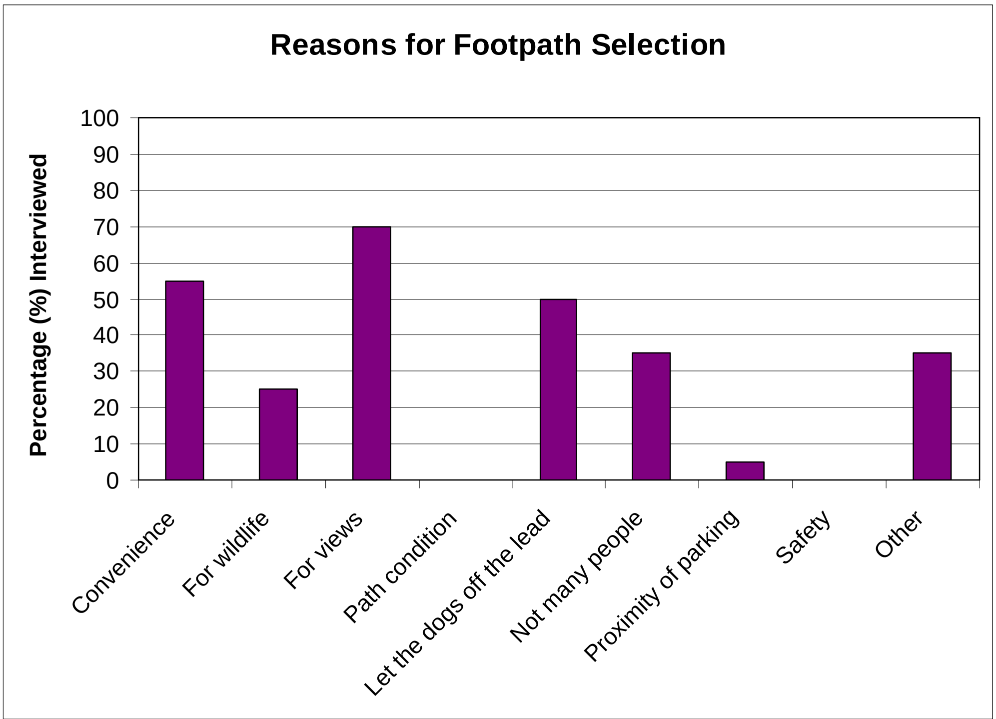
Figure 5.5 Activity Undertaken on Footpaths



- Most used the footpath network frequently, between once a week to twice a day for residents, but for a lesser frequency by non-residents;
- Users were loyal to the routes they took, though other routes within and outside the study area were also used;

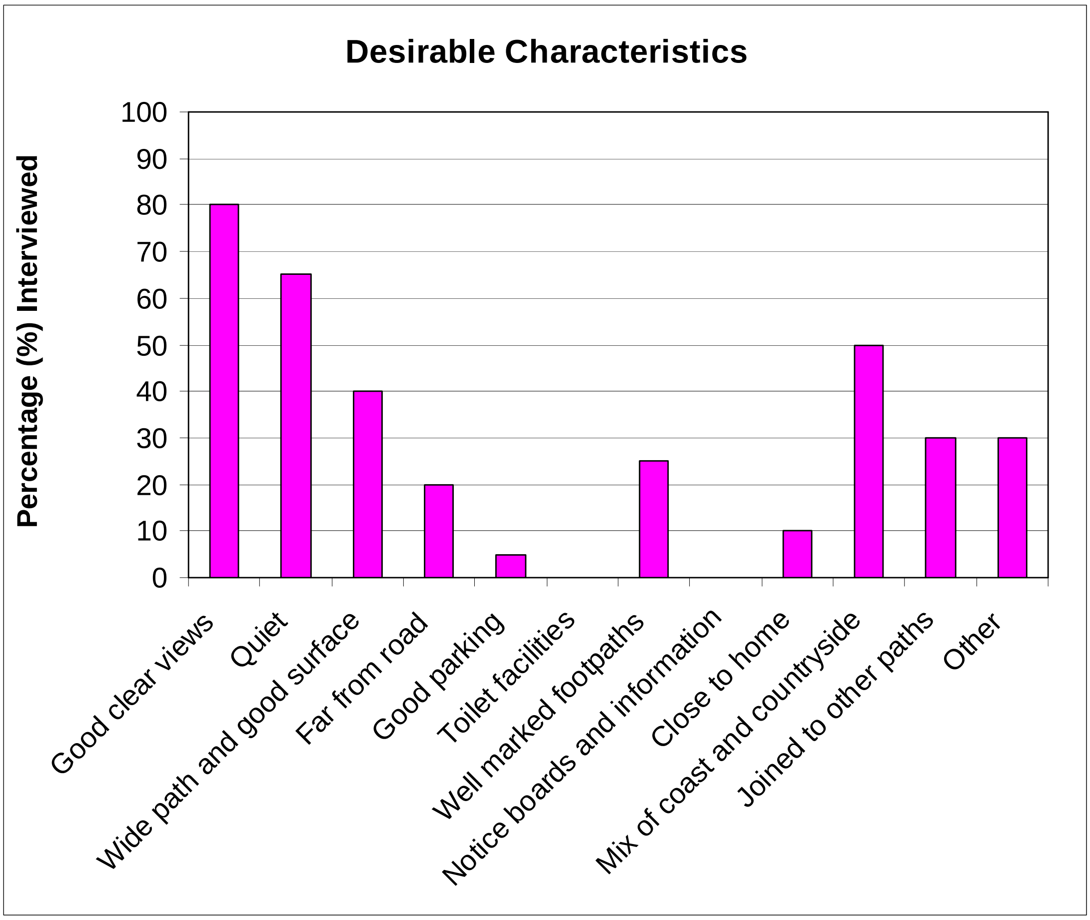
- Users were expecting to spend an average of 1 hours and 55 minutes outdoors, with duration outdoors ranging from 20 minutes to over 7 hours;
- The majority (65%) intended to follow a circular route, whilst the remainder returned the same way;
- The reasons for choosing the route were: the views (70%), convenience (55%), they could let dogs of the lead (50%), there were not many people (35%), the wildlife (25%), and other recreational reasons (35%), as presented in **Figure 5.6**;

Figure 5.6 Reasons for Footpath Selection



- The users identified the most desirable characteristics of a footpath as good views (80%), peace and quiet (65%), a mix of countryside and coast (50%), good condition of the footpaths (40%), connections to other footpaths (30%), well marked footpaths (25%), and far from the road (20%). Graphical representation is shown in **Figure 5.7**;
- The vast majority (90%) of users were over 45 years of age, and none were under 25 years of age;
- Just under half (45%) of those surveyed were in full time employment, with 30% in part time employment, and the remaining 25% were retired;
- The average number in a household was 1.9, with few or no dependents; and
- The majority of users were female (65%), though in general females were as likely to be on their own as males.

__Figure 5.7 Desirable Characteristics for Footpaths__



6 CONCLUSIONS

6.1 Footpath Network

6.1.1 The footpath network across the study area provides access to a unique blend of coastal and inland environments, with long distance views to the west and along the coastal path, whereas views are enclosed with occasional distant glimpses of Exmoor, the Quantocks, or the Brean Down/Bleadon Hills and Mendips. The footpath network is extensive in terms of the variability of routes available, particularly to the west of Wick Moor Drove (the C182) and north of the villages of Knighton, Burton, and Shurton. Footpaths are generally unsurfaced (i.e. no tarmac/concrete) or follow the route of farm tracks often comprising compressed earth with occasional buried stones. Particularly fine views are found along the east to west running ridge to the north of the small settlements and to the south west of Hinkley Point A Power Station. Views along the footpaths to the east of Wick Moor Drove are generally constrained by the low lying topography and numerous field boundaries.

6.2 Footpath Use

6.2.1 The majority of use of footpaths is by local residents, though on occasion visitors resident significant distances from the area (e.g. in excess of 15 miles) visit and use the footpaths for their value as a rather unique resource. Use is predominantly favoured for walking dogs, though for some footpath lengths use is specific to the interest along that footpath (such as fishing along the coastal footpath, and access to cattle near to Stolford). Fishing and horse-riding were the only formal activities undertaken on or near to the footpath network, and in relatively restricted areas, and in low numbers.

6.2.2 The numbers of visitors and users of the footpath network were lower than anticipated, particularly along the coastal path. The surveys were staggered through the day, all sites were surveyed around the expected and unexpected peak times (the lunchtime and afternoon peak) on weekdays and weekends. There was little difference in visitor/user numbers between weekdays and weekends, which may be indicative of the fact that mostly residents use the footpath network and mainly for the regular exercise of walking their dogs.

6.2.3 In order to generate yearly use numbers for the footpath network as a whole, the methodology presented in the Foundation for Water Research's Manual on Assessing the Benefits of Surface Water Quality Improvements (FWR, 1996) have been used to calculate a range of user numbers for the footpath network surveyed. The calculations are based on the visitor numbers for 'river' based sites, and those for coastal based sites. The river-based site numbers are calculated based on the number of residential properties in the surrounding area, with a low medium and high range provided by three ranges (500m, 800m, and 3km). The coastal based calculations are based on the counts made during the surveys undertaken, which are then multiplied using factors identified in the Manual (FWR, 1996) relating to informal recreation (which based on the summer counts is likely to be an overestimate of the number of trips). **Table 6.1** presents the ranges of values for total visitor numbers for the footpath network surveyed. The numbers for a honeypot (river) site and the average based on the coastal site calculations are in the same area, and based on the average distances of those interviewed from the area, the interest features in the area, the use of the footpath network though moderate, is of a high local value.

Table 6.1 Calculated Total Use of Network Surrounding the Site

Calculation Basis	Users per year
River-based calculations	
500m	4,500
800m	9,250
3km Honeypot	21,100
Coastal site calculations	
15/07 Survey	36,000***
18/07 Survey	16,800
26/08 Survey	29,600
30/08 Survey	8,900*
Average	22,825**

6.2.4 Based on the calculated user numbers in **Table 6.1**, an indication of the expected density of use for the individual footpaths based on the counted users from the surveys presented in this report, is provided in **Table 6.2**. These counts and the density of use shown on **Figure 5.1** point to a greater intensity of use of the footpaths along and adjacent to Bullen Drove at the far western end of the study area, but moderate to low levels of use within the remainder of the network in the study area. The point based multiplier estimates are around 75% higher than those based on residential population.

HINKLEY – RECREATIONAL ACCESS – FOOTPATH SURVEY

Target	Description
Physical Conditions	
Length	
Surface	Concrete - then gravel / mud track, then grass.
Width	5m +
Boundary	Bounded at southern end by farm buildings and walls, then open field boundaries.
Watercourse crossings	None.
Gates	Open gate access to southern end, and open gate into field (halfway).
Stiles	None.
Steepness/Slopes	Level.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	Signpost at southern end at farm entrance.
Ease of access	Easy / clear access at southern end and to start of FR 02.
Obstructions	None, ~~[illegible]~~

Target	Description
Animals (agricultural)	None.
Lighting present	None.
Other 1	
Other 2	
Other 3	
Other 4	
Notes	

Target	Description
Qualitative Conditions	
Tidiness	Muddy access track, but grass in field is short.
Open views description	Contained views to north and south, due to topo and ~~two~~ field boundary hedges. Slightly extend views to the east with distant view of Power Station but interim views obstructed by nearby field boundaries. Views to West and South West obstructed by farm buildings.
Views of…	Farm buildings Agricultural land. Field boundary hedges and trees. Distant power station. Low hills.
Photographs	
01 02	Southern access and signpost. Farm access.
03 04	Access track looking West. Access track looking North.
05 06	" " " " " " " NE.
07 08	" " " East. " " " SE.
09 10	" " " South. " " " South W.
11 12	Halfway access gate. From halfway gate looking North to FP02.
13 14	" " " " South. View North from near northern end.

Survey Site	Hinkley, Somerset
Footpath Reference Number	F 02
Surveyor Signature	[signature]
Survey Date	16th December 2009

HINKLEY – RECREATIONAL ACCESS – FOOTPATH SURVEY

Target	**Description**
Physical Conditions	
Length	
Surface	Low ~~arable~~/vegetable crop.
Width	NA. Not demarcated.
Boundary	Field boundary.
Watercourse crossings	None at southern end.
Gates	Gate at southern end.
Stiles	None at southern end.
Steepness/Slopes	Gentle slope up to 1 in 8 at southern end.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	None.
Ease of access	Open access beside southern gate, but no path through crop, hence access is inhibited.
Obstructions	Crop obstructs passage.

Target	Description
Animals (agricultural)	None.
Lighting present	None.
Other 1	
Other 2	
Other 3	
Other 4	
Notes	

Target	Description
Qualitative Conditions	
Tidiness	Crop growing in field.
Open views description	View from southern end looking north obstructed by topography. View south as FR 01.
Views of…	Agricultural land.
Photographs	
01 02	Southern access point. Southern access looking North.
03 04	" " " NE. " " " East.

Target	Description
Physical Conditions	
Length	
Surface	Grass trackway.
Width	1.5 – 3m.
Boundary	Hedgerows either side.
Watercourse crossings	1 watercourse / pond preventing access.
Gates	None.
Stiles	None.
Steepness/Slopes	Level.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	Sign at southern end.
Ease of access	Open access until the pond / watercourse is reached which ~~[illegible]~~ cannot be passed by pedestrians.
Obstructions	Pond.

Target	Description
Animals (agricultural)	None.
Lighting present	None.
Other 1	
Other 2	
Other 3	
Other 4	
Notes	Signs of horse riding. Halfway, inaccessible to foot pedestrian due to large pond. At southern entrance to lane, trees on left hand side obscure views from properties on the right hand side, and hide the sun in the evenings. They were apparently planted as screening for the old Hinkley C. Can they be trimmed down?

Target	Description	
Qualitative Conditions		
Tidiness	Part overgrown with thistles and nettles. Also damp in places with a large pond halfway.	
Open views description	Views contained by hedgerows bounding and corner of path.	
Views of…	Hedgerows Trees.	
Photographs		
1	Mid point looking at pond (N wards).	095
~~2~~	~~South end looking up path~~	

Survey Site	Hinkley, Somerset

Target	**Description**
Physical Conditions	
Length	
Surface	Grass.
Width	4m +
Boundary	Northern end of field, and field hedgerow.
Watercourse crossings	None.
Gates	1 gate halfway, gate in open.
Stiles	
Steepness/Slopes	Northern half slopes approx 1 in 5.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	Signpost at south east end.
Ease of access	Could not pass through gate adjacent to Bishops Wood due to extensive depth and extent of deep mud (cattle disturbed ground). Access otherwise clear.
Obstructions	Mud area prevented passing through halfway gate adjacent to Bishops Wood.

Target	Description
Animals (agricultural)	None present at time of survey, but northern field is grazed by cattle.
Lighting present	None.
Other 1	
Other 2	
Other 3	
Other 4	
Notes	

Target	Description
Qualitative Conditions	
Tidiness	Short grass. Muddy and sodden in places.
Open views description	Views to north restricted by hedgerow. Views to the south only of far distant hills due to topography and hedgerow boundaries to the east and west. View of power station over the northern boundary hedgerow.
Views of…	Hedgerow field boundaries. Quantocks to the south. Power Station over the top of the northern hedgerow.

Target	Description
Physical Conditions	
Length	
Surface	Arable crop. Northern 1/3 Central 1/3 – grassland. F07 Southern 1/3 – field margin (arable) grass strip from concrete beside ditch / stream. with concrete slab bridge. no railings
Width	c. 3ft. or less.
Boundary	Open arable field / grassland / arable field margin
Watercourse crossings	None.
Gates	None.
Stiles	North end? Stile in the middle, hedge partially obstructing. 2nd stile in central 1/3, good condition. 3rd stile at 1/3 southern (N) end. Good condition F07 - stile good condition.
Steepness/Slopes	Steep slope c. 1 in 5 at north end. Otherwise general gentle to flat.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	Signpost at stile. Route slightly different in the middle compared to OS map route, but signposted. Stile with signpost at junction with F07. F07 - southern end - gate accessible with small sign.
Ease of access	Relatively easy access.
Obstructions	None.

Target	Description
Animals (agricultural)	None.
Lighting present	None.

HINKLEY – RECREATIONAL ACCESS – FOOTPATH SURVEY

Target	**Description**
Physical Conditions	
Length	
Surface	Grass margin of arable field.
Width	1 – 2.5 m narrowing to overgrown as it reaches the F12
Boundary	
Watercourse crossings	Hedgerow to the north, open field to the south. One small metal footbridge crossing.
Gates	Gate at west entrance – open.
Stiles	~~None~~. Two stiles fair condition.
Steepness/Slopes	Level.
Adjacent watercourses	~~None~~. At eastern edge along F12 length.
Adjacent cliffs/slopes	None
Signposting/locating	Signpost at West entrance.
Ease of access	Open access until reaching the F12 stretch which becomes impassable due to crops and thistles.
Obstructions	Thistles and crop along F12 reach.

Target	Description
Animals (agricultural)	None.
Lighting present	None
Other 1	
Other 2	
Other 3	
Other 4	
Notes	Becomes impassable as it continues along route F12.

Target	Description	
Qualitative Conditions		
Tidiness	Grass long 1 – 2ft, and ground uneven. Overgrown after the first stile and 2nd field.	
Open views description	View contained by surrounding hedgerows around the field, with only occasional view of top of Mendips in the far distance. Eastern edges has closed views to the S and W, due to hedgerow and tall crop. View of field and hedge to the east but nothing else.	
Views of...	Arable field Hedgerows. Trees Quantocks.

HINKLEY – RECREATIONAL ACCESS – FOOTPATH SURVEY

Target	**Description**
Physical Conditions	
Length	
Surface	Grass.
Width	Field. 1½ ft wide trampled grass route, with stone slabs per 10m.
Boundary	Hedge and wall at southern side.
Watercourse crossings	Cross a shallow ditch but dry. ~~None~~. Cross a water filled ditch using ~~stile~~ pedestrian gate and fenced bridge (1.2m wide).
Gates	Entry gate at eastern end. Crossing ditch.
Stiles	None.
Steepness/Slopes	Within 1-2m across whole length.
Adjacent watercourses	None.
Adjacent cliffs/slopes	None.
Signposting/locating	Signpost at eastern end.
Ease of access	Eastern gate easy to open.
Obstructions	None.

Target	Description
Animals (agricultural)	None.
Lighting present	None.

Huntworth Roundabout (see **Figure 25.13**)	BW23/4 - 490m outside works area. BW23/69 – 470m outside works area.

APPENDIX 25E: PROPOSED PROW MITIGATION AND ENHANCEMENT MEASURES AGREED UNDER SECTION 106 WITH SOMERSET COUNTY COUNCIL

APPENDIX 25E: PROPOSED PROW MITIGATION AND ENHANCEMENT MEASURES AGREED UNDER SECTION 106 WITH SOMERSET COUNTY COUNCIL

Table 1: Priority enhancement actions proposed from commencement of construction (see **Figures 25.17** and **25.18**)

Reference	Action	Length
1b-1	Resurfacing (550m) of PRoW WL24/7	550m
1b-2	Resurfacing Lilstock Car Park	$512m^2$
1b-3	Resurfacing (840m) of PRoW WL23/45 (Bullen Drove) and part of PRoW WL23/43 north of Bullen Drove PRoW to include verge side parking	840m
1b-4	Provision of 2 pedestrian gates, 2 small footbridges, and 3 waymarks along PRoW WL23/21	223m
1b-5	Provision of 4 pedestrian gates and 2 waymarks along PRoW WL23/55	305m
1b-6	Provision of 5 pedestrian gates, 1 footbridge, and 4 waymarks along PRoW WL23/59	760m
1b-7 & 1b-11	Provision of 4 pedestrian gates, 1 small footbridge, and 3 waymarks along PRoW WL23/44 (including part of WL23/42)	756m
1b-8 & 1b-11	Provision of 1 pedestrian gate and 1 waymark along PRoW WL24/21 (including part of WL23/42)	528m
1b-9 & 1b-10	Provision of surface improvements (950m), 7 pedestrian gates, 1 bridleway gate, 2 small footbridges, and 3 waymarks along PRoW WL23/61	1,679m
1b-12	Provision of 1 pedestrian gate at the southern end of the Development Site boundary on PRoW WL23/56 (to be carried out by EDF Energy)	185m

Table 2: Enhancement actions proposed from commencement of construction (see **Figures 25.17** and **25.18**)

Reference	Action	Length
2-1	Upgrade the permissive path from PRoW WL24/10 (Range Quadrant Hut) to WL11/22 to PRoW (footpath) also requiring 7 pedestrian gates and 2 waymarks	+2,388m
2-2	Create a new bridleway along Woolstone Lane also requiring 2 bridleway gates and 1 waymark	+620m
2-3	Diversion of PRoW WL23/43 north of WL23/110 to WL23/95	Decrease by 230m
2-4	Provision of surface improvements (470m), 4 bridleway gates, 1 small footbridge, and 1 waymark along PRoW WL23/71	1,102m
2-5	Diversion of PRoW WL23/95 from WL24/9 to WL23/43 (new junction) requiring 2 waymarks	+1,115m
2-6	Accommodation works along PRoW WL23/95 from WL23/61 to WL23/102	1,796m
2-7	Accommodation works along PRoW WL23/102	114m
2-8	Upgrade PRoW WL23/106 to bridleway also requiring 2 waymarks	+529m
2-9	Diversion of West Somerset Coast Path (WL24/9)	720m
2-10	Benhole Lane to Burton-Shurton Road (WL23/48) diversion of southern end onto alternative route created during construction to connect to Burton-Shurton Road	Decrease by 340m
2-11	Diversion of PRoW WL23/52, and surface works, two pedestrian gates, and two waymarks	+279m
2-12	Upgrade PRoW WL23/61 to bridleway, from WL23/71 north to WL23/95	+440m
2-13	Upgrade PRoW WL23/71 to bridleway	+1,102m
2-14	Upgrade PRoW WL23/102 to bridleway	+87m
2-15	Upgrade PRoW WL23/95 to bridleway from WL23/61 east to WL23/102	+1,669m

Table 3: Reinstatement of PRoW (including permanent diversions) to be carried out at the end of construction of Hinkley Point C (see **Figure 25.18**)

Reference	Reinstatement Action	Length
3-1	Permanent diversion of altered route of PRoW WL23/48 from WL23/110 north to WL23/95 along western bund	831m
3-2	Reinstate diverted route of PRoW WL23/110	1,070m
3-3	Upgrade part of PRoW WL23/110 (diversion) to bridleway	380m
3-4	Reinstate route of PRoW WL23/56 from WL23/110 to reconnect with WL23/56 to the south of the construction area; route would follow a line proposed by Somerset County Council, and will incorporate pedestrian gates and waymarks where required	836m
3-5	Create new PRoW bridleway from WL23/56 and connect to WL23/110	450m
3-6	Upgrade PRoW WL23/56 from 3-5 to 3-8, to bridleway status	637m
3-7	Reinstate diverted route of PRoW reference WL23/69; route would follow a line proposed by Somerset County Council, and will incorporate pedestrian gates and waymarks where required	991m
3-8	Create permanent PRoW (bridleway) from Shurton Lane (entrance to the Emergency Access Road) to C182	1,063m
3-9	Create permanent PRoW from WL23/48 to PRoW created for Action Reference 3-8	250m

APPENDIX 27A: COMMUNITY IMPACT REPORT

CONTENTS

FIGURES

APPENDICES

FOREWORD

This report provides a summary of the community impacts arising from the Hinkley Point C (HPC) Project.

The report draws upon the extensive Environmental Impact Assessment (EIA) and other assessments which form part of the HPC Development Consent Order (DCO) application to the Infrastructure Planning Commission (IPC). It does not contain new evidence or assessments.

The report is distinctive, however, in reporting those impacts as they affect individual communities, or groups of communities. For example, in relation to Bridgwater it brings together and reviews the principal impacts affecting the town that are otherwise set out in a range of assessments such as the **Transport Assessment**, the **Socio-economic Assessment**, the Noise or other chapters of the Environmental Statement. In this way, communities and other interested parties can gain an understanding of the principal impacts on their areas.

In the same way, the report also brings together the mitigation proposed in the application as it affects those communities.

The intention of the report is to provide an understanding of how particular communities are likely to be affected by the HPC project.

1. COMMUNITY IMPACT REPORT

1.1 Introduction

1.1.1 The proposed Hinkley Point C Project (the HPC Project) would be one of the largest construction projects in the UK. It would also be the first of a new generation of nuclear power stations which are necessary if the UK is to meet its energy needs and to do so in a way which is consistent with challenging targets for climate change mitigation. Its scale and characteristics suggest that it may have the potential to both bring significant benefits and to cause significant impacts over a wide area but, particularly, in the districts of West Somerset and Sedgemoor.

1.1.2 Those benefits and impacts are comprehensively assessed in a range of documents which support the application to the Infrastructure Planning Commission (the IPC) for a Development Consent Order (DCO). In particular, the application includes a comprehensive Environmental Impact Assessment (EIA), **Transport Assessment**, **Economic Strategy**, **Planning Statement** and a number of other supporting documents. The EIA includes a comprehensive **Cumulative Impact Assessment**.

1.1.3 It is also relevant, however, to consider the effects of the HPC Project on a spatial scale, i.e. to consider what the effects of the project would be on the individual communities which might be most affected by the HPC Project.

a) Study Areas

1.1.4 This report considers the principal effects of the HPC Project on those communities which have the potential to be most affected. Assessment areas are based on administrative boundaries, parishes for rural areas and wards or groups of wards/town council areas for urban areas. These have been the basis for assessments undertaken both by EDF Energy and by the local councils. Two criteria have been used to identify the areas to be studied, as follows:

- those communities which host either the main HPC development site or one or more of the proposed associated development (AD) sites, or where traffic impacts are likely to occur on public highways; and
- those areas slightly further afield where the assessments suggest that there may be a concentration of more than 100 non-home based workers drawn to the area to work on the HPC Project during its construction.

1.1.5 The combination of these two criteria means that the following areas have been selected for study:

- Stogursey Civil Parish (CP) – includes settlements of Shurton, Burton, Knighton, Wick and Stolford (HPC development site);
- Bridgwater CP (Associated developments: Bridgwater A and Bridgwater C accommodation campuses) and Bridgwater ward cluster;
- Cannington CP (Associated developments: Cannington bypass and Cannington park and ride);

- North Petherton CP (Associated developments: Junction 24 park and ride, freight management facilities and temporary postal courier consolidation facility and induction centre);
- Otterhampton CP (Associated developments: Combwich Wharf and freight laydown facility);
- Puriton CP (Associated developments: Junction 23 park and ride facility, freight management facility, consolidation facility for postalcourier deliveries and induction centre);
- Williton CP (Associated developments: Williton park and ride facility);
- Burnham and Highbridge (ward cluster);
- Minehead (ward cluster);
- Taunton (ward cluster); and
- Weston-super-Mare (ward cluster).

1.1.6 Between them, these areas include all areas where there is a direct physical impact of the HPC Project but also include the areas where the most significant transport or socio-economic effects might arise.

1.1.7 **Figure 27A.1** outlines the 'ward clusters' that have been derived from the Gravity Model, which compartmentalises the likely distribution of non-home-based workers across an area within 60 minutes travel distance from the Hinkley Point C site.

1.1.8 **Figure 27A.2** to **27A.8** show the spatial areas identified in the list above (Civil Parishes), covering local areas of Stogursey, Bridgwater, Cannington, North Petherton, Otterhampton, Williton and Puriton, including elements of the HPC development relevant to those areas.

b) Approach

1.1.9 The impacts which are described in this report are drawn directly from the other assessments undertaken to support the DCO application. This report does not repeat the findings of these assessments, therefore, an explanation of the baseline conditions or of the methodology which has been employed in order to determine the likely significant effects of the HPC Project are comprehensively set out elsewhere.

1.1.10 Instead, it concentrates on reporting the principal assessed effects as they would impact on the communities that have been studied.

1.1.11 It is important to make clear that this is not intended to be a full summary of the EIA or the other assessments. It is intended, however, to accurately reflect the principal effects of the HPC Project on individual communities.

1.1.12 The report concentrates only on principal effects. The nature of these effects inevitably varies between communities. For some, for instance, the visual impact of the proposed elements of the HPC Project is important. For others, different impacts may be important such as transport, accommodation impacts or other impacts such as education or leisure. For each community, the report draws upon the assessments to bring together the most relevant effects.

1.1.13 From this report, therefore, the reader will be able to understand the nature and the significance of the project's effects on individual communities. It may help, however, for the reader to have some more context about the HPC Project as a whole. For this purpose, **Appendix A** comprises Section 3 of the **Planning Statement** which is submitted with the Development Consent Order (DCO) application. The appendix explains EDF Energy's overall approach to the project, the strategies which have been put in place to manage transport, accommodation and other effects and it provides a brief description of the principal elements of the HPC Project, i.e. the development of the HPC development site itself and the development of locations for associated development. The associated development sites provide transport or accommodation facilities to support the HPC Project and to enable its effects to be managed and reduced.

c) Mitigation

1.1.14 In order to further limit and mitigate the potential adverse effects of the HPC Project, a series of mitigation measures are proposed. Where these relate to effects on individual communities, they are described in this report. It is appropriate, however, to set out some of the wider mitigation proposals which are relevant across the project as a whole because these have an effect wherever the HPC Project impacts fall. Again, a more detailed explanation is provided in Sections 7 to 9 of the **Planning Statement** but a summary of the principal mitigation obligations proposed as part of the DCO application is contained in **Appendix B**.

1.1.15 It may be helpful, however, to summarise some of the more relevant elements of the proposed mitigation strategies here, as they are relevant to each of the communities affected.

d) Accommodation

1.1.16 At the peak of construction, it is estimated that the HPC Project would require 5,600 workers. Through commitments to local education, training and recruitment, EDF Energy anticipates that 34% of the peak construction workforce would be recruited locally (i.e. from residents who would not need to move home in order to work at Hinkley) but that 66% or 3,700 workers would come into the area and require accommodation.

1.1.17 In order to estimate where these workers may live, a Gravity Model has been developed which takes account of journeys to Hinkley and the availability of accommodation. In this way, estimates have been made of the numbers of workers that would be likely to seek temporary accommodation within different towns and villages. The demand generated by Hinkley should bring benefits for the local housing sector and the tourist/bed and breakfast market. A significant number of people have also registered their interest in letting out rooms to Hinkley workers.

1.1.18 Nevertheless, it is possible that adverse effects could arise if there is too great a concentration of demand in one place or if the overall demand affects prices or disadvantages those who are less able to compete in the housing market. Accordingly, EDF Energy has proposed a series of mitigation and management measures including:

- 1,510 workers' campus spaces are to be provided on the HPC development site and at two sites in Bridgwater (Bridgwater A and C);

- An Accommodation Management Strategy is proposed, which would match workers with available accommodation and monitor any adverse effects. The Accommodation Management Office would have the ability to direct workers away from areas where too high a concentration of workers might begin to impact adversely on the housing market; and
- A Housing Fund of £5m is to be provided to the local authorities to assist with a range of initiatives targeting the low cost housing sector locally where housing impacts could have the most significant effect.

e) Leisure

1.1.19 The influx of workers into the area would generate increased demands for leisure facilities. At the same time, the development of the Bridgwater A campus would result in the loss of the former Innovia social club and playing fields. In order to address these effects, EDF Energy proposes the following commitments:

- £250,000 towards the provision of new or improved sports and leisure facilities within West Somerset;
- £500,000 towards providing new or improved sports and leisure facilities within the parish of Stogursey;
- £250,000 as a contribution towards the new swimming pool under construction in Bridgwater;
- £500,000 to provide new or improved sports and leisure facilities within Bridgwater;
- £500,000 to provide new or improved sports and leisure facilities within Cannington; and
- EDF Energy would also make available to the public the sport pitches proposed as part of Bridgwater A, Bridgwater C and HPC development site (on-site) accommodation campuses.

f) Public Services

1.1.20 EDF Energy is providing funding to meet the WSC, SDC and SCC's costs in addressing all of the planning issues raised by the HPC Project.

1.1.21 In addition, particular attention has been paid to the impact on public services such as education and health to ensure that the HPC Project pays for any increased costs on those services.

1.1.22 In relation to education, EDF Energy is committed to a programme in local schools which would help to educate and inspire children in subject areas such as science and technology. Commitments are being made to new training facilities for West Somerset Community College and investment is committed into the Energy Centre at Bridgwater College as well as funding being provided for a new Construction Skills Centre on land immediately north of Cannington. In addition, in order to mitigate potential impacts arising from workers' children coming to the area, EDF Energy proposes:

- £610,000 towards new or improved classrooms in Cannington and Bridgwater;

- funding a teaching post for five years to oversee the integration of Hinkley workers' children into local schools; and
- a funding formula based on existing Council policy to meet costs if the demand for Hinkley workers' children to be educated exceeds the capacity of local schools.

1.1.23 In relation to health, EDF Energy has contracted with a company called Duradiamond to operate medical facilities at HPC and to meet the large majority of the health requirements of HPC workers. Further commitments are made to meet any additional costs on the local health services arising from any need for construction workers to use local health services including, for instance, ambulance call out costs.

1.1.24 As part of the site preparation Section 106 Agreement, EDF Energy committed to fund a Hinkley Readiness Study for £60,000 which would enable the health services to prepare properly for the Hinkley Point C development. As part of the DCO Section 106 Agreement, EDF Energy intends additionally to commit to:

- A formula to fund ambulance call out costs, estimated to be in the region of £134,000;
- A formula also to cover the potential cost of additional NHS referrals from construction workers, estimated to cost £50,460; and
- A phased payment of £604,990 to the Primary Care Trust to address any additional costs of dealing with the health requirements of workers families – even though those families are expected to take up existing housing accommodation.

g) Community Safety

1.1.25 **Appendix B** includes a schedule which sets out a range of commitments which EDF Energy is making to the Emergency Services and other providers to ensure that they can provide an appropriate service to the HPC Project and to the community in relation to any matters associated with the HPC Project. The principal measures that would be put in place to ensure community safety include:

- **A Worker Code of Conduct**.
- Contingency Response Arrangements and any necessary training for the relevant services.
- Funding a local Community Safety Beat Team within the police service.
- Funding the Community Safety staff at West Somerset and Sedgemoor District Councils and Somerset County Council in order to enhance liaison between parishes, HPC, community partnerships and the Emergency Services.
- Funding two community outreach workers and one young person support worker to work with traditionally hard to reach groups in order to encourage them to engage with the training and employment opportunities available through the HPC Project.

h) Community Impact Fund

1.1.26 In recognition that it is unlikely to be possible to mitigate all impacts of the development directly, EDF Energy has proposed a Community Impact Fund of £20 million in order to address the effects of residual impacts which are not so easily defined. These less tangible impacts might be described as impacts on the "quality of life" of local communities.

1.1.27 Accordingly, it is intended that the Community Impact Fund is available for communities to submit bids for projects which enhance the local quality of life. An initial down payment from the Fund is proposed as part of the planning consent for the Site Preparation Works but the Fund as a whole would be available over the life of the construction programme.

i) Highway Improvements and Transport Strategy

1.1.28 A comprehensive transport strategy is proposed to reduce and manage traffic impacts of the development. The strategy seeks to maximise the use of sustainable modes of travel. For construction materials, therefore, investment is proposed into a temporary jetty at the HPC development site and into improvements to the wharf facilities at Combwich so that a significant proportion of abnormal indivisible loads (AILs) and bulky construction materials can arrive by sea. Freight management sites are also proposed so that heavy goods vehicle movements can be limited in the peak hours. A comprehensive bus strategy is also proposed, based on direct buses from the accommodation campuses in Bridgwater and main centres of population, from four park and ride sites and direct bus services from accommodation campuses. In this way, traffic impacts are limited but there would still be a substantial change in traffic flows on certain routes. The proposals also include the provision of a bypass around Cannington village, to the west, which would direct construction traffic away from Cannington village at the peak of the construction phase (in 2016).

1.1.29 As part of the proposed HPC Project, several highway improvement schemes (including modification to existing alignments and junctions/roundabout arrangements, and enhanced safety measures) are proposed to existing public highways. The proposed schemes would comprise:

- A38 Bristol Road/The Drove Junction – small increase in the width of the highway to improve the operation of the junction, through increasing the width of the right turn lane from Bristol Road into the Drove to reduce queuing.
- A39 Broadway/A38 Taunton Road Junction – changes to signal arrangements, minor carriageway realignments to improve operation of the junction and pedestrian facilities.
- A38 Bristol Road/Wylds Road Junction – increase in width of carriageway and right turn lane to assist right turns and reduce queuing.
- Wylds Road/The Drove Junction - carriageway widening to Wylds Road, The Drove and East Quay at approaches to the junction and provision of a left-turn slip road from Western Way into Wylds Road to improve operation of the junction.
- A39 New Road/B3339 Sandford Hill Roundabout – new four arm roundabout to improve safety of junction including minor realignment of existing carriageway.
- M5 Junction 23 Roundabout – provision of signalisation and minor carriageway alterations within highway land to improve operation of roundabout and minor improvements to road markings at Dunball roundabout.
- Washford Cross Roundabout – new four arm roundabout to improve safety of junction.

- Claylands Corner Junction – minor carriageway widening to improve operation of the junction.
- C182 Farringdon Hill Lane, Horse Crossing – provision of horse crossing to improve safety for horses and riders.
- Cannington Traffic Calming Measures – traffic management measures including skid resistant surfacing, 20 mph speed limit, new puffin crossing on High Street, new footway on High Street, new zebra crossing on Rodway and associated signage.
- Huntworth Roundabout – increase in width of eastern arm of roundabout to reduce queuing, amendments to white lining to improve circulation and provision of signage.

1.1.30 All of these wider strategies, therefore, provide an important context within which to consider the specific impacts of the HPC Project on individual communities.

1.1.31 An overarching **Framework Travel Plan** has been prepared to support of the DCO application and considers the management and movement of people involved in the construction and operation of the proposed development. Site-specific Travel Plans would be prepared for the HPC development site, for the associated development sites and for the operational phase of the HPC power station. These Travel Plans would encourage the overall modal share to be sustainable, and concentrate on areas where there could be further improvements (walking and cycling, public bus to park and ride sites, car sharing and rail use).

1.1.32 A Transport Co-ordinator would be appointed by EDF Energy and be in place throughout the construction and early operational phases of HPC. They would be responsible for the management, development and implementation of the Travel Plans for the duration of the HPC Project. Additionally, a Transport Review Group would be established with members of the key transport stakeholders and EDF Energy, and a separate Transport Forum, a body of town and parish councillors, would represent the views of the local community.

1.1.33 A range of measures have been developed to promote and facilitate the use of sustainable modes of travel wherever possible. Some of these measures are more prescriptive and would be delivered as part of the transport strategy for the HPC Project, whilst other softer measures are set out within the **Framework Travel Plan**. They include:

- a bus fleet funded by EDF Energy to transport workers to and from the HPC development site including direct bus services, park and ride bus services and campus bus services, the services would be free to workers (transport strategy);
- a strict requirement that workers would only use the mode of transport allocated to them be it direct bus, campus bus or park and ride bus (transport strategy);
- constraining and controlling on site parking to essential workers and visitors only (transport strategy); and
- the promotion of viable sustainable transport options such as walking, cycling, public bus and rail through encouragement, and provision of information and incentives as appropriate (Travel Plan).

2. STOGURSEY/HINKLEY POINT C

2.1 Introduction

2.1.1 Hinkley Point is located on the north Somerset coast, in a relatively remote area to the east of West Somerset, in Stogursey Civil Parish. As the host of the HPC development site, Stogursey would experience a number of impacts throughout the construction, operational and post-operational phases of the development. These would include the direct impacts of construction activity and impacts on local villages and road networks related to construction traffic. The scale of the development itself would significantly affect the character of the areas closest to the HPC development site and there may be effects from the influx of construction workers to the area.

2.2 Context

a) Local Area and Community Impacts

2.2.1 The HPC development site is in the east of West Somerset District. The site is in Quantock Vale ward and Stogursey Parish, which is a rural parish comprised of Stogursey itself and a series of small hamlets, of which Shurton, Burton, Knighton, Wick and Stolford are the closest to the HPC development site.

2.2.2 The population of the area is around 1,270 (parish) or 2,100 (ward), and has a relatively old age profile compared to the national average, with the proportion of over 65's having grown significantly since 2001. There are around 600 homes in the area. In economic terms, the area has a low benefit claimant rate, although it has a high proportion of retired residents, low unemployment and does not suffer from high levels of deprivation. It is an attractive rural area.

2.2.3 Within the Stogursey area, the main HGV route from the M5 motorway via Bridgwater and Cannington (the C182 (Rodway)) runs past Combwich via Withycombe Hill to Wick Moor Drove, through to Hinkley Point.

2.2.4 The elements of the HPC Project anticipated to result in impacts on the community in Stogursey are:

- the proximity of the HPC development site, resulting in construction traffic and large scale on-site construction-related activity during the construction period;
- the proposed on-site accommodation campus for non-home-based construction workers; and
- the physical presence and operation of the power station through its estimated 60 year life until it is decommissioned and the land restored.

2.2.5 Indirectly, there could also be effects on local residents and users of community facilities and public services. Quantock Vale has a number of basic sports facilities, predominantly based in community halls. These are principally clustered around Holford and Kilve, outside the Stogursey parish. There is one primary school within the parish (with 21 surplus places). The general amenity of the area could be affected by the adverse impacts of the development on traffic, visual amenity, noise levels and recreation. The construction of the power station would also impact on a number of local rights of way in addition to the long distance coastal path.

2.2.6 **Figure 27A.2** shows a plan of the parish, including elements of the HPC project in the local area.

b) HPC Accommodation Campus

2.2.7 The nature of the HPC Project is such that associated development is required to support the construction phase – in this case an accommodation campus for up to 510 construction workers is proposed on the HPC development site during construction and would be removed after the construction phase of the HPC Project is complete.

2.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

2.3.1 The ward that includes the settlements listed above closest to Hinkley Point has a total population of around 2,100 people, and due to the presence of an on-site accommodation campus is forecast to accommodate around 510 construction workers at peak construction (in 2016), which is around nearly four times the average annual number of new residents in the area.

2.3.2 In terms of accommodation capacity in the local area, the overall increase of 510 people referred to above is based on an assumed 97% occupancy of the on-site accommodation campus to account for short-term stays and turnover of residents, which accounts for around 495 of the workers, with a remainder of around 15 construction workers requiring accommodation in other sectors in the area. In Stogursey Parish, immediately adjacent to Hinkley Point, the main direct socio-economic impact would therefore be from the on-site accommodation campus.

2.3.3 This equates to a significant population increase and, therefore, concerns about impacts of non-home-based construction workers on the supply of accommodation, public safety, community cohesion, the provision of services, movement of workers on local roads for leisure/recreation and the capacity of community facilities have been raised in consultation.

2.3.4 The 15 non-home-based construction workers which are estimated to be drawn to the local area but not to be staying in the accommodation campus are anticipated to be split between different types of accommodation (private rented (c.10), tourist (c.<5), owner-occupied (c.5). Using conservative estimates this is identified as being within existing capacity of local accommodation, taking into account turnover and vacancies.

2.3.5 EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce and accommodation management measures and the commitments outlined in Section 1 of this report. The number of workers attracted to seek accommodation in Stogursey should be regulated by the available supply, and the primary option would be for placement in the on-site accommodation campus, before consideration of other sectors. The campus would play a significant part in limiting the impact that might otherwise arise from large numbers of workers seeking accommodation very close to the HPC development site. The accommodation office for the HPC Project would have the ability to direct new applicants away from the area if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit Stogursey and its residents in the event that any problems occur.

2.3.6 Similar issues arise in relation to education. Workers resident in Stogursey may seek to place their children in the local primary school, although only a small proportion of workers are expected to bring children. In 2010/11 the school had spare capacity of 21 places, which would provide adequate capacity at peak construction. There may be some benefit from workers' children supporting the school.

2.3.7 The wider mitigation strategies outlined in Section 1 address other impacts on health and public services.

2.3.8 In terms of community cohesion, it is recognised that a concentration of worker population could have an impact on the quality of life of some residents for example in terms of perceptions of community safety, impacts or perceived impacts on access to public services and community facilities.

2.3.9 It is not possible to quantitatively assess the extent to which workers living on the on-site accommodation campus would seek to use facilities in the nearby villages. However the design and operation of the campuses has taken into account the lessons from previous experience of Sizewell B with facilities on site and direct bus services to the larger settlements to limit impacts on the immediate area.

2.3.10 The on-site accommodation campus has been located in an area as far north as possible, away from Shurton. EDF Energy recognises the concerns of some in the local community regarding an on-site accommodation campus and has proposed a number of mitigation methods to address them.

2.3.11 The accommodation campus layout has been designed to reduce potential noise, light and visual impacts on the local community. The quieter, residential buildings have been positioned along the southern boundary of the site and the recreational facilities have been positioned to the north of the campus development, at the furthest point from Shurton village. There is no direct pedestrian access or road to the village of Shurton and access would only be obtained from Wick Moor Drove, the main access point. This would ensure that the development includes effective measures that prevent unofficial shortcuts from the site to Shurton and Stogursey.

2.3.12 A Main Site Neighbourhood Support Scheme has been established which recognises that hamlets in the immediate vicinity of HPC (Shurton, Burton, Knighton, Wick and parts of Stolford) would be affected by a unique combination of issues throughout the duration of the construction period. The Scheme contains elements to mitigate potential effects of noise and property value impacts that may arise. This includes a property price support scheme to assist residents who wish to move away and a noise insulation scheme that offers properties double glazing and ventilation.

2.3.13 A Code of Conduct, attached as an Appendix to the **Community Safety Management Plan,** has been written to set expectations of how workers use accommodation and the way they interact with the local community, and would:

- communicate the behaviour expected of workers and outline the means by which the Code would be communicated to all workers;

- outline the role of employers;
- outline the monitoring mechanism for the Code during the construction works; and
- inform the community of the standard of behaviour they should expect from workers and their employers.

2.3.14 The potential for adverse health impacts has been addressed in the **Health Impact Assessment**, which has been informed by a survey of local residents to understand concerns about the possible effects of the development. Based on the level of emissions (air and noise) generated on site, their intermittent nature and duration and minimal opportunity for community exposure, the risk to community health is not assessed to be of a level to quantify any meaningful adverse health outcome, and would be further managed through a range of controls on the construction of HPC which are set out in the **Environmental Mitigation Management Plan (EMMP)** and related subject-specific management plans.

2.3.15 Once the HPC power station is operational, there are few activities with the potential to affect the health of local communities. The core community concern is the potential risk from radiological exposure. However, following a review of the available scientific evidence and a detailed radiological assessment, EDF Energy's assessment is consistent with that undertaken by the Government that, for an individual living near to Hinkley Point, the direct health risk from radioactivity to the environment would be low, and is well within International Commission on Radiological Protection (ICRP) guidelines set to protect health. EDF Energy recognises that regular communication is an important means of reducing concerns.

2.3.16 Specific mitigation and community support initiatives within the **Health Action Plan** are targeted to benefit the local communities surrounding the HPC development site and off-site associated development sites based on the demographic information contained within the community profile and feedback from consultation events. Mitigation includes continued communication, information provision and liaison to further reduce concerns, and where necessary support local communities. To address the possible perception of a change in the local environment, local hamlets would be supplied with monitoring data for air quality and noise compared against the modelling data contained in the ES.

2.3.17 In addition, a number of the project-wide mitigation proposals have a particular significance for Stogursey. In addition to the Main Site Neighbourhood Support Scheme, the mitigation proposals include:

- an investment of £500,000 in new or improved leisure and recreation facilities in the parish; and
- £500,000 from the Community Impact Fund is "ring fenced" for Stogursey Parish, for projects to enhance the local quality of life and the parish would be able to bid for further funds over the length of the construction period.

b) Transport

2.3.18 The main access road serving the existing Hinkley Point Power Station Complex is the C182 (Rodway), which is a single carriageway road passing from Hinkley Point south-east to the village of Cannington. The C182 (Rodway) routes to the east of

Shurton and to the west of Combwich and passes through the centre of Cannington to join the A39 to the south of the village.

2.3.19 Given the location of nearby villages to the key HGV route (the C182 (Rodway)) and HPC, the general area is likely to experience impacts related to traffic flows, and subsequent community impacts related to air quality, noise and vibration and visual amenity. The C182 (Rodway) is an important route for the community to access the main road network, Bridgwater and larger settlements and it would be a much busier route throughout the construction period. That said, increases in traffic flows on the C182 will not be of a scale that will create any issues of traffic congestion.

2.3.20 Unlike impacts in Cannington and Bridgwater, the local route in Stogursey would also experience increased flows of HGVs as a result of movements of HGVs between the Combwich freight laydown facility and the HPC development site as well as less frequent movement of Abnormal Indivisible Loads (AILs) from Combwich to the HPC development site.

2.3.21 The HPC transport strategy for the HPC Project limits these flows as far as possible by using Combwich Wharf for the water-borne delivery of AILs and bulky construction goods; using the temporary jetty to bring bulk concreting materials to the site by sea, by restricting car parking on the HPC development site, reducing trips by private car through consolidating trips at the proposed park and ride sites at Cannington, Williton, Junction 23 and Junction 24, and by managing HGV movements to limit impacts on the peak hours. Nevertheless the change in flows on the C182 (Rodway) would be significant throughout the construction phase. Measures are proposed to limit HGVs to the C182 (Rodway) locally to protect the amenity of the rural areas to the west.

2.3.22 Specific local junction improvements are proposed as part of a highway improvement package to be implemented in conjunction with the HPC Project. These works comprise minor junction realignment at Claylands Corner, approximately 500 metres east of Hillside Farm and 2km to the east of Stogursey. The works would comprise:

- minor widening at eastern edge of carriageway opposite junction;
- relocation of existing give-way line, approximately 2 metres to east;
- minor relocation of kerb line to edge of carriageway by approximately 1m;
- widened carriageway strip to be finished in tarmac to match existing;
- finish with new edging strip; and
- provision of various new signage.

2.3.23 In addition, to address effects on the C182 (Rodway) the following measures are proposed:

- Preparation of a scheme, and subsequent monitoring, to implement speed restrictions on the C182 (Rodway);
- a horse crossing at Farringdon Hill Lane to ensure the ability to cross the C182 (Rodway) safely at the busiest times for pedestrians and riders.

2.3.24 An assessment of the significance of the predicted increases in traffic as a result of the HPC Project is provided within **Volume 2, Chapter 10** of the **Environmental**

Statement and the **Transport Assessment**, (see **Annex 7** of the **Environmental Statement)**.

2.3.25 The scale of the increase in HGVs and buses on the C182 (Rodway), to the north of proposed Cannington bypass, in 2013, during the early construction phase of HPC, is predicted to increase from 206 HGVs/buses (2-way daily flows) in the Reference Case (existing flows, plus committed development plus background growth) scenario to 1,483 HGVs/buses with the HPC Project (including the mitigation package described above). This is an increase of approximately 620% of existing HGV and bus flows on the C182 (Rodway), to the north of the proposed Cannington bypass, although overall daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would only increase by around 25% as HGVs and buses only make up a small proportion of overall traffic.

2.3.26 In 2016, the 2-way daily flows at the same assessment point are predicted to be 1,698 HGVs/buses with the HPC Project, an increase from 246 HGVs/buses in the Reference Case. This is equivalent to an increase of approximately 590% of existing HGV and bus flows on the C182 (Rodway), to the north of the HPC development site. The above figures include existing and future road traffic associated with Combwich Wharf – including HGV movements between the Combwich freight laydown facility and the HPC development site - and is considered to be representative of the conditions likely to be experienced in Stogursey in 2016, when Combwich would be operational. Again overall increases in traffic flows as a result of the HPC Project (including mitigation) would be much lower at 24.1% in all vehicles on the C182 to the north of the proposed Cannington bypass.

2.3.27 In 2021, the 2-way daily flows on the C182 (Rodway) north of the bypass are predicted to decrease by around half from the 2016 peak to 773 HGVs/buses with the HPC Project, representing an increase from 218 in the Reference Case. This is equivalent to an increase of approximately 250% of existing HGV and bus flows on the C182 (Rodway), to the north of the HPC Project. Overall increases in traffic flows as a result of the HPC Project (including mitigation) would again be much lower at 15.2% on the C182 (Rodway) to the north of the proposed Cannington bypass.

2.3.28 The impact of these increases in traffic flows is assessed in relation to its impact on severance, pedestrian delay, pedestrian amenity, driver delay and accidents and safety. Severance is defined as perceived division that could occur within a community when it becomes separated by a major traffic artery and is therefore particularly relevant the consideration of impact on the community. The increases described above with regard to the C182 (Rodway), to the north of proposed Cannington bypass, in 2013, 2016 and 2021, is considered to be **moderate adverse** in terms of severance. For the other assessment criteria, the increase in total traffic does not meet the relevant thresholds and therefore the impact is considered to be **negligible,** with the exception of driver delay, which is considered to be **minor adverse** in 2013.

2.3.29 The character of the C182 (Rodway) through Stogursey would therefore experience a significant change as a result of HGVs and buses associated with the HPC Project. This would however only be temporary, throughout the course of the HPC Project, and would not persist following completion of the construction phase, when there would just be operational staff on the site. It is also relevant that the above figures are worst-case, particularly with regard to anticipated bus numbers. Timetables and routes have been developed for modelling purposes for the **Transport Assessment** to assess the worst-case impact that the provision of such services could have on the highway network. As the development progresses, EDF Energy would refine the bus services, routes and timetables to best serve the actual distribution of workers and this should enable the number of bus trips to be significantly reduced.

2.3.30 It is also relevant that the predicted increase in total traffic flows on the C182 (Rodway), to the north of the proposed Cannington bypass, is significantly lower than the predicted increase in HGVs and buses and is lower than 30% during all assessment years.

c) Noise and Vibration

2.3.31 The construction and operational phases of HPC are likely to result in local community impacts on residential properties and people using local amenity spaces, as a result of temporary HGV and bus traffic flow increases and construction-related noise during set hours.

2.3.32 Construction activity is to be concentrated north of grid line 144750mN, as far away from residents of Doggetts, Shurton and Burton as practical. The greatest potential for impact is from short-term construction activities associated with the construction of the emergency access road and early landscaping close to the southern site boundary, resulting in a noise increase at the nearest residential dwellings (related to construction traffic and works).

2.3.33 During short-term activities associated with construction of the emergency access road, close to Bishops Farm House, the daytime noise limit is likely to be exceeded.

2.3.34 Similarly, worst-case predicted noise levels during early landscaping and final landscaping operations at the closest approach to the southern boundary of the Southern Construction Phase Area (SCPA) are likely to exceed the adopted daytime noise limit at Doggetts. Due to their proximity to residential dwellings, these activities would be restricted to normal working daytime hours only. These occurrences would also be of short duration, and landscaping works early in the construction programme would help to reduce the noise impacts from the later works.

2.3.35 Whilst higher construction noise levels are expected at public amenity areas such as footpaths (West Somerset Coast Path and Benhole Lane) and open spaces (Pixies Mound), the overall significance of the disturbance caused to their users is likely to be lower than residential properties as the users would be transient and only in the area for a short period of time. A **minor** to **moderate adverse** impact is predicted, depending on the location along the Public Right of Way (PRoW).

2.3.36 The noise impact at the assessed residential receptor locations of all other construction activities associated with the HPC development site is assessed as being of **minor** to **moderate adverse** significance due to a combination of the additional distance attenuation and physical screening by the natural and formed topographical features. This assessment is applicable for both daytime and evening periods. Some activities could potentially result in more significant impacts at residential dwellings if undertaken at night (23:00-07:00hrs), notably, construction of the emergency access road and its bridge over Bum Brook, landscaping works south of the 144750mN site boundary, some activities associated with deep excavation works (rock ripping and crushing) and construction of the temporary accommodation campus. For this reason, these works would be prohibited during this period (23:00-07:00hrs) to minimise impacts to residential properties.

2.3.37 Potential noise impacts from the generation of road traffic on local public highways during HPC construction have been assessed. During this phase, without mitigation, **minor to moderate adverse** impacts would occur in 2016 (peak construction) along the main route connecting the Williton park and ride site with the HPC development site (through Stringston and Stogursey). This relates to noise from early morning and late evening minibus movements at the beginning and end of the principal shifts, for which the assessment assumes that all minibuses travelling between Williton and the HPC site will use this route. In reality, some of these services will route via the A39, through Cannington, with others (minibus only) travelling through Stringston and Stogursey to pick up construction staff that are resident there. Furthermore, given the relatively few houses that front directly onto this part of the road, the impacts would be limited.

2.3.38 Noise and vibration impacts from both on-site construction machinery and from construction vehicles on public highways has the potential to result in combined impacts at certain sensitive locations. Of the neighbouring residential dwellings, only Doggetts would be potentially affected by such in-combination effects, due to the relative short separation distance between the C182 (Rodway) (Wick Moor Drove) and construction works.

2.3.39 As part of the mitigation and control proposed, a **Noise and Vibration Management Plan** (**NVMP**) is to be implemented during construction. This plan includes a provision to continuously monitor noise levels at representative residential properties in the villages of Knighton, Shurton, Burton and Wick. In addition, residents would be able to contact a 24-hour noise complaints telephone number so appropriate mitigation steps could be investigated. In recognition of the overall scale of the proposed HPC development construction, EDF Energy has committed to the Main Site Neighbourhood Support Scheme which allows residential property owners in the villages of Shurton, Burton, Knighton, Wick and Stolford to apply for either secondary glazing or new double-glazing, with acoustic ventilation, to be fitted. These schemes are offered irrespective of the significance of the fact that the noise impacts are not forecast to be at a level that would normally trigger the need for insulation.

2.3.40 Once built, each UK EPR unit would undergo a commissioning phase which would result in short-term noise generation as machinery and processes are being tested. However, the significance of the potential noise impacts to residential and amenity receptors in Stogursey would be **minor adverse**.

2.3.41 Noise from the fully operational nuclear power station would also result in both continuous and intermittent noise generation. Whilst the noise levels from this phase would be significantly lower than during construction, noise impacts would be permanent. The assessment, using worst-case assumptions, determined that the predicted operational noise levels in Shurton, Burton and Knighton might be audible under certain meteorological conditions. However, the levels predicted would be below recommended guidelines values for the protection of amenity and the prevention of sleep disturbance. The operational impact on residential properties in Stogursey was therefore assessed as being of **minor adverse** significance.

2.3.42 Road traffic noise impacts on the C182 (Rodway) and Stogursey village once the site is operational would be of **minor adverse** significance.

d) Air Quality

2.3.43 The community impact in terms of air quality is anticipated to be in relation to dust and particulate emissions resulting from the HPC development site construction works, and off-site road traffic emissions linked to construction traffic.

2.3.44 The construction phase of Hinkley Point C is likely to result in impacts on properties close to the HPC development site, in terms of temporary reductions in air quality predominately from construction dust from on-site sources during particularly dust-generating construction activities.

2.3.45 Whilst the potential impact may vary throughout the various stages of the construction phase, the primary air pollution sources will be those typical of any industrial construction site that may cause dust and particulate matter to be emitted to the atmosphere. These sources relate to activities which will include (but not be limited to) earthworks; excavations, drilling and compacting; crushing and grinding and cement batching. This source will dominate the overall particulate concentrations at nearby receptors, with the contribution from the other sources being comparatively insignificant.

2.3.46 The potential for construction dust impacts at residential dwellings in proximity to the HPC development site will be limited to the period between 2011/2012 and late 2014, given that after 2014 the works with significant dust-generating effects would have been concluded, and the separation distance between the source and receptors will be at maximum.

2.3.47 The potential for construction dust impacts will be greatest at the time when an earth bund to the south of latitude 144750mN is being formed (2013 construction scenario). However, once the bund and early landscaping land profiling are completed, these works will result in an increase in the separation distance between potential dust generating construction activities and the human receptors during later construction phase works, thus having an overall effect of reducing potential long-term construction phase impacts. Similarly, whilst the on-site workers accommodation campus located in the south-east of the SCPA is being constructed during this phase, there is the potential for elevated construction dust levels to be experienced, particularly at the closest residential receptors to the site (e.g. Doggetts). Once completed, however, it will result in separation between potential dust generating construction activities and the receptors, and will also provide some screening. There will therefore be an overall effect of reducing the potential for long-term construction dust impacts at nearby residential receptors post construction of the on-site workers accommodation campus.

2.3.48 EDF Energy is committed to implementing best practice to reduce dust impacts to acceptable levels. However, to make the impact assessment more transparent, impacts from dust have been assessed in the ES, prior to implementation of best practices for dust control.

2.3.49 The majority of the human receptors in Stogursey, will be located over 200m from the closest point of site activity during this period of construction. Of the assessed human receptor locations only Bishops Farm House, Doggetts and Shurton village are be closer than 200m, therefore, with the exception of these three receptors, the significance of construction dust impacts at human receptor locations is predicted to be negligible during this phase of the construction works.

2.3.50 The significance of construction dust impacts at Shurton Village have been assessed as of **minor** significance during this phase of the construction works. Potential impacts at Bishops Farm House and Doggetts would be considered to be of **major** significance during this phase of the construction works without mitigation. Meteorological conditions that may lead to elevated dust and particulate matter at Doggetts and Bishops Farm House from on-site construction activities are prevalent for only 4.2% and 2.4% of the time, respectively. The impact from dust at these three human receptors would be local, direct, likely and medium-term.

2.3.51 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**. As a result of the implementation of control methods, the assessment carried out for the Environmental Impact Assessment concludes that there would be **no significant residual impacts**.

2.3.52 Regardless of which of the two modelling methodologies are adopted for both annual mean and 1-hour mean future year NO_2 concentration predictions, with regard to potential impact on the 104 human receptor locations along those routes associated with traffic generated by the combined HPC Project, vehicular emissions during the construction and operational periods of the combined HPC Project (i.e. 2013, 2016 and 2021 scenarios), are **not significant**.

2.3.53 Mitigation measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content. In addition, the **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards.

e) Landscape and Visual

2.3.54 The nature of the construction phase of HPC would have a significant adverse impact on landscape character and visual receptors during construction that cannot be completely mitigated by landscape screening due to its scale.

2.3.55 The most significant temporary visual impacts (up to **major adverse**) would be on the residents of Shurton, Burton, Knighton, Wick and local farms, and also on users of other elevated areas of landscape, such as the north-eastern summits of the Quantock Hills AONB.

2.3.56 The assessment of the potential impact to the visual amenity of users of the Public Right of Way (PRoW) within the study area and of amenity space at Wick Common during the construction concludes that medium-term and temporary impacts, ranging from **minor adverse** to **major adverse**, are predicted to occur for users of the individual PRoW as they pass through the zone of influence.

2.3.57 In the residential areas around the application site, where landscaping including landform and vegetation has the highest screening potential, the majority of visual impacts would be of **moderate adverse** significance. However, due to the proximity of the HPC, localised **major adverse** impacts would remain for users of PRoW along the coastline adjacent to the site. Some of these impacts would slightly decrease in the long-term, when the planting proposals, including off-site mitigation measures, mature.

2.3.58 Landscape proposals adjacent to the local settlements to the south of the site would be implemented in the first phase of construction to provide early screening and reduce adverse impacts on the local community. Temporary screening along the north-west site boundary (during construction), and off-site planting on Fairfield Estate would also be implemented in the early stages of construction to provide additional screening and minimise impacts.

2.3.59 A screening bund along the north-west boundary would offer some screening for PRoW users to the west of the site during early phases of construction, and the early implementation of landscape proposals in the southern part of the site would reduce visual impacts on the local residents of Shurton, Burton, Knighton, Wick and local farms and would continue to provide mitigation through the operational phase of HPC

2.3.60 The planted landscape bund (area of raised ground) is proposed to screen the on-site accommodation campus at the time of construction, providing visual mitigation and some noise attenuation both for Doggetts and for the residents of Shurton. The lighting design, together with the landscaping strategy, has been designed to minimise light spill to the residential properties to the south.

2.3.61 The main visual impacts within the Parish of Storgursey during the operational phase of HPC would occur to PRoW users along the coastline to the west of the site, residents of Wick and nearby farms, residents along the northern edge of Stogursey, residents of Stolford and PRoW users around Pixies Mound.

2.3.62 Impacts would range from major to minor adverse during year 1 of the operational phase, and from moderate to minor adverse during year 15 of the operational phase.

2.3.63 During construction and operational phases, the most efficient mitigation measure with most immediate screening effect would be the proposed bund along the north-western boundary of the HPC development site varying in height from 2m to 8.5m (relative to adjacent ground levels). The temporary bund would be implemented during site preparation works and would be effective for screening the HPC development in the short distance, predominantly from the adjacent PRoW. On completion of the construction phase, the land outside of the permanent development site would be restored as proposed in the **Landscape Restoration Plan**. The proposed landform and planting would be effective in screening views of the lower levels of the proposed development and from the majority of viewpoints within the Parish, only the highest HPC structures would be seen above the existing ridge of Green Lane (to be retained) or the proposed landform and planting.

2.3.64 The HPC construction mitigation measures include off-site mitigation measures proposed following consultation with the owners of the land to the west of the HPC development site. The off-site landscape and visual mitigation measures include:

- wildflower meadow planting;
- hedgerow reinforcement;
- changes in management of the existing hedgerows allowing their full growth; and

- woodland screen planting.

2.3.65 This off-site planting is aimed specifically to minimise visual impacts on Fairfield House and the surrounding land. It also aims to mitigate local visual impacts from some local PRoW within the Coastal – Lilstock sub character area. The off-site planting scheme proposed following consultation with the landowners of the land to the west of the HPC development site would continue mitigating landscape and visual impacts during the HPC operational phase (at year 1 (to a lesser extent) and year 15 of the operational phase and beyond).

2.3.66 The visual receptors likely to be affected by the proposed off-site mitigation include users of PRoW in the vicinity of the north-western boundary of the HPC development site and around Burton; residents of Knighton, Burton and Fairfield; walkers and users of PRoW within the Fairfield and eastern part of the Coastal - Lilstock landscape character sub areas.

2.3.67 Visual receptors on PRoW (No. WL 23/46) and the residents of adjacent Knighton Farm would benefit from the change in the management of existing hedgerows on the local ridge in the foreground of the view. The fully grown hedgerows would contribute to screening of the proposed HPC development and the existing Hinkley Point Power Station Complex, however the magnitude and nature of impacts would not change significantly, even when the hedgerows are fully grown.

2.3.68 Visual receptors on PRoW around Burton and motorists would benefit from the change in the management of existing hedgerows visible on the local ridge in middle ground. The fully grown hedgerows would contribute to screening of HPC.

2.3.69 Off-site planting proposals have also been prepared to mitigate the impacts on Pixies Mound. They include predominantly woodland and hedgerow planting along Wick Moor Drove to screen the HPC proposed development when viewed from Pixies Mound. It is estimated that the landscape proposals around Pixies Mound would reach their full screening potential at year 15 of the operational phase (while providing only partial screening during the construction phase), when the proposed HPC development would be almost entirely screened from this viewpoint , due to the proximity of planting.

f) Amenity and Recreation

2.3.70 The nature of the HPC Project would result in temporary impacts on the access to and amenity of users of recreation features currently in use by the community – this includes public rights of way and amenity spaces.

2.3.71 During construction, all Public Rights of Way (PRoW) within the development site boundary (including the coastal edge) of the HPC development would be obstructed and public access would be prohibited for health and safety reasons for the duration of the construction works. This loss of PRoW is considered to be a **moderate adverse** impact. This includes the temporary obstruction of the West Somerset Coast Path during the construction, and dismantling and removal of the jetty and seawall, which as a nationally important PRoW would result in a **major adverse** impact.

2.3.72 In terms of the wider PRoW network, the presence and retention of PRoW to the east, south, and west of the HPC development site would maintain an indirect access route to Stolford from the settlements of Burton, Shurton and Knighton. Consequently, although direct routes would be affected, particularly during the closure of the West Somerset Coast Path, indirect routes would be available which have minimal lengths along or crossing roads and lanes.

2.3.73 The reopening of the West Somerset Coast Path would reinstate many of the routes from Knighton, Shurton and Burton to the coast and to the east of Hinkley Point.

2.3.74 Following consultation with local residents, Stogursey Parish Council, and SCC's Rights of Way officers, it was agreed that a temporary alternative route should be provided around the boundary of the development site. This route would also be used by those following the West Somerset Coast Path for the duration of jetty and seawall construction. On completion of these, it was agreed that the West Somerset Coast Path would be reinstated as soon as possible, incorporated into the sea wall design.

2.3.75 Mitigation measures to be implemented through PRoW diversions and alternative routes would reduce the overall loss of PRoW and provide improvements to over 13.3km of Public Rights of Way after the construction phase is complete.

2.3.76 During the construction phase, access would be permitted to the southern area between the inner security fence and the development site boundary fence (in response to requests from local residents for the provision of circular walks). This would provide a maximum of 13ha of 'permissive' access land (the equivalent of more than 15 full-sized football pitches) for public recreation and amenity for the residents of Shurton in particular.

2.3.77 Once HPC is complete, as well as designated and permissive PRoW and bridleway enhancement action, general access would be permitted to the land north of Shurton up to Green Lane, which would be restored and enhanced as a nature reserve. This would provide up to 87ha of 'permissive' access land for amenity and recreation for the residents of Shurton as well as the wider public.

2.4 Summary of Impacts and Mitigation

2.4.1 This section of the report has reviewed the impacts which the HPC Project would be likely to have on the settlements in the direct vicinity of Hinkley Point – Shurton, Burton, Knighton, Wick, Stolford and Stogursey.

2.4.2 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Stogursey has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

2.4.3 Due to its location on the road network and its direct proximity to the HPC site, the area is forecast to experience some of the most significant impacts of the HPC Project during all stages. As a result, significant mitigation proposals have been proposed for the area, including:

- a Noise Insulation Scheme for properties most affected by construction noise;
- a Property Price Support Scheme;
- £500,000 from the Community Impact Fund is to be committed to projects within Stogursey parish;

- £500,000 is to be spent in Stogursey parish on new or improved leisure facilities. In addition, on-site sports facilities at the accommodation campus would be accessible to members of the public; and
- early landscaping of the southern boundary and the longer term creation of a landscaped site including a large nature reserve with full public access.

2.4.4 In addition, of course, Stogursey parish is well placed to secure income from construction workers who wish to stay close to the HPC development site and to benefit from the employment and training opportunities offered by HPC.

3. BRIDGWATER

3.1 Introduction

3.1.1 As the closest large town to Hinkley Point, and being located on the principal transport route from the M5 motorway to Hinkley Point, Bridgwater is anticipated to experience a number of impacts arising from the construction and operational phases of the HPC Project and any post-operational phases associated with the off-site associated developments, where relevant. It is also well placed to secure a number of the benefits of the HPC Project.

3.2 Context

a) Local Area and Community Impacts

3.2.1 Bridgwater is the principal town in the vicinity of Hinkley Point, and is the administrative centre of Sedgemoor District, approximately 12km south-east from the HPC development site. The town lies on strategic transport routes, between Junction 23 and Junction 24 of the M5 motorway and on the River Parrett and has historically maintained a strong industrial base. From Bridgwater, the A39 runs from the motorway through to Cannington and on to Hinkley Point.

3.2.2 The population has grown at a relatively fast rate and is younger in profile than the district, county and region. Unemployment is currently relatively high, however, and there are pockets of deprivation (within the 10% most deprived in the UK), particularly to the east of the town centre. The area suffers from a number of economic weaknesses, including a low skills base and low qualifications and educational attainment, and there is a high level of benefit claimants.

3.2.3 Bridgwater has a number of community assets, including sports and recreation facilities. These include Bridgwater Sports and Social Club, Bridgwater and Albion Rugby Football Club, Bridgwater College and Sports Centre and the East Bridgwater Sports Centre. There is one library in Bridgwater and five community centres. A swimming pool is under construction at Chilton Trinity School. There are five GP surgeries and a cluster of other primary healthcare facilities, including an optician.

3.2.4 Community impacts are most likely to arise during the HPC Project in Bridgwater as a result of:

- the nearby location of the HPC development site, which would make Bridgwater an attractive location for non-home-based construction workers;
- the location of Bridgwater on strategic transport links from the M5 motorway and on and around the A39; and
- the construction of the associated developments.

3.2.5 Community impacts are most likely to arise during the construction phase of both the HPC development site and the local associated developments, during this period traffic would be at its highest and workforce numbers would be greatest.

3.2.6 Bridgwater would experience the largest increase in population (close to 1,400) of non-home-based construction workers during the peak of the construction phase compared to other areas in the vicinity of HPC, because it is the largest population and service centre in the area and the closest to Hinkley Point. As such, there are concerns locally that there could be indirect impacts on community cohesion, access to public services, capacity of community facilities (for example, schools) and the capacity of the accommodation and housing sectors.

3.2.7 **Figure 27A.3** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

3.2.8 Bridgwater urban area would host two of the associated developments which are proposed to support the construction of HPC during the construction phase (Bridgwater A and Bridgwater C accommodation campuses). Freight Management and oark and ride facilities are also proposed at Junctions 23 and 24 of the M5 motorway and these are considered in other sections of this report.

3.2.9 The nature of the HPC Project is such that a significant non-home-based workforce is required during the construction phase. The need for purpose-built accommodation campuses is explained in the **Accommodation Strategy**.

3.2.10 The sites for the accommodation campuses are located to the north-east of Bridgwater town centre. The accommodation campuses at Bridgwater A and Bridgwater C would provide bedspaces and associated leisure and recreational facilities for 1,000 construction workers at peak. EDF Energy considers that the sites are well suited to accommodation campus development as they are sustainably located close to the centre of Bridgwater, and are of sufficient size to accommodate the necessary number of occupants to support the provision of communal services and facilities.

3.2.11 The **Alternative Sites Assessment** describes the site's credentials compared with other sites, whilst the **Consultation Report** describes how the sites were selected.

3.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

3.3.1 In Bridgwater the local impacts would be likely to include:

- an influx of non-home-based construction workers which, at its peak would represent 57% of the usual average annual number of new residents moving to Bridgwater – the workers would principally occupy the accommodation campuses, although they would also be attracted to a range of other accommodation types in the town;
- Loss of existing sports facilities at associated development sites (Bridgwater Sports and Social Club and Bridgwater Albion Rugby Football Club training pitch) – addressed through re-provision and/or financial mitigation;
- potential impacts on community cohesion, crime, anti-social behaviour and policing; and

- the largest concentration of non-home based workers in private rented accommodation, and probably the largest number of families.

3.3.2 The Bridgwater ward cluster (the population of which is predominantly made up of Bridgwater urban area) is expected to accommodate close to 1,400 non-home-based construction workers in 2016, when the construction workforce is at its peak (up to 1,000 of these construction workers would be accommodated in the Bridgwater A and Bridgwater C campuses, although it is assumed that there will be around 3% vacancy at peak construction). This is equivalent to around 57% of annual new residents, based on the number of new residents observed in the 2001 Census. The cluster itself has a population of 50,000 people.

3.3.3 Although non-home-based workers would represent a relatively low proportion of the total population of Bridgwater, concerns about impacts of non-home-based construction workers on public safety, community cohesion, the provision of services and the capacity of community facilities have been raised by SDC, the Town Council and by others during consultation.

3.3.4 In particular, concerns have been expressed that there may be impacts relating to the capacity of tourist and private rented accommodation sectors, and the capacity of local schools, particularly if the level of non-home-based construction workers exceeds the 'central scenario' estimated by EDF Energy, and which is outlined in **Volume 2**, **Chapter 9** of the **Environmental Statement**.

3.3.5 The central scenario is based on a workforce profile at peak construction of 5,600 construction workers on the HPC development site and Bridgwater A and C sites combined, of which 66% would be 'non-home-based' i.e. requiring short-term accommodation. In Bridgwater, taking account of the existing supply of accommodation, the cost of accommodation and the proximity to Hinkley Point to the site, approximately 1,400 non-home-based construction workers are estimated to be accommodated at the peak of construction activity. It is estimated that they would be split between accommodation sectors in the following proportions: around 970 in purpose-built accommodation campuses (assuming a small level of spare capacity due to allow for effective management), 110 in the private rented sector, 110 in owner-occupied accommodation, 65 in tourist accommodation and 135 in latent accommodation (rooms let within existing houses).

3.3.6 In Bridgwater, at a conservative estimate there is currently capacity to accommodate this demand in existing capacity with an estimated 100 vacant tourist bedspaces and at least 130 private rented bedspaces even in the August peak. At other times of the year, vacancy is estimated to be much higher in the tourist sector. If non-home-based construction workers exceed the central scenario (as modelled and assessed in **Volume 2**, **Chapter 9** of the **Environmental Statement**), capacity issues could arise, although the extent of available capacity means that the increase would need to be significant.

3.3.7 The figures demonstrate the benefit of the campus accommodation in meeting the majority of the demand. The nature of the accommodation campuses also means that they would be attractive to workers seeking short-term accommodation, sometimes at short notice, which might otherwise be more difficult to find. Through the managed signposting of workers, the HPC accommodation office would seek to reduce pressure in specific locations or on specific public services. The influx of workers would also provide a boost to the local housing market and to the bed and breakfast sector, as well as providing welcome income for those who choose to let out rooms. It is likely that this would cause some increase in supply and some investment to enhance the quality of local accommodation which would be a benefit which would last beyond the peak period of construction activity.

3.3.8 There is a potential for adverse effects to arise if the demand for accommodation is too great, although the accommodation campuses address the bulk of demand. Nevertheless, the peak period may see a lower availability of accommodation in some sectors. There is already considerable movement within Sedgemoor and Somerset between different towns, particularly amongst private tenants, so in part this would be addressed by the natural flow of people moving to other locations with lower rents and/or higher capacity.

3.3.9 However EDF Energy has also been concerned to prepare for possible adverse impacts locally and to address this potential impact EDF Energy has committed to a Housing Fund of £5 million described in Section 1 of this report. That Fund has the capacity to assist households or to create at least 1,000 bedspaces and, as a result, the overall impacts on the accommodation sector in Bridgwater are assessed to be **negligible**. Any investment from the Housing Fund in permanent housing would result in long-term benefits for Bridgwater.

3.3.10 The campus sites would be provided with 24 hour security and would be pro-actively managed. EDF Energy would put in place a **Worker Code of Conduct** to ensure high standards of worker behaviour. The Code of Conduct is attached as an appendix to the **Community Safety Management Plan.** It has been prepared to set expectations of how workers use accommodation and the way they interact with the local community.

3.3.11 Based on experience at Sizewell and elsewhere, EDF Energy does not expect difficulties to arise in the local community from the temporary presence of construction workers. The Code of Conduct would be rigorously enforced if necessary but, in practice, the workers are expected to contribute positively to local shops and services. Many would be short-term residents, focused on their work at Hinkley. Others would stay longer, some would bring families and there is no reason to expect that they would not make a positive contribution to Bridgwater.

3.3.12 As described in Section 1, EDF Energy has worked closely with the local authorities and with the Emergency Services and has committed to a range of measures that would assist community safety and co-ordination between services to address any issues arising from the introduction of workers into the area. Funding is proposed for Community Safety services and a Community Beat Team. In addition, measures are proposed to ensure that the existing community benefits from the investment at HPC. Bridgwater schools would receive investment to inspire interest in science, technology and energy. Outreach workers and a dedicated Youth worker would work in the community to encourage hard-to-reach groups to engage with the training and employment opportunities available at Hinkley and the procurement team at EDF Energy is already working with local companies to help them become "Hinkley Ready" so that they can compete for contracts at Hinkley. A visitor centre is established at Kings Square in Bridgwater and an employment Brokerage has been established in Bridgwater with Job Centre Plus to provide maximum access locally to Hinkley employment opportunities.

3.3.13 Through these and other measures, the HPC Project has the potential to become integrated into the local community and to contribute positively.

3.3.14 Potential impacts, on public services are addressed in the mitigation package of measures described in Section 1. The **Heads of Terms for the Section 106 Agreement** propose advanced mitigation through early investment in school capacity in Bridgwater and a formula for payment towards increasing education capacity if monitoring identifies further impacts beyond existing capacity. In addition, EDF Energy is investing £3 million in the Energy Centre at Bridgwater College to further enhance its capacity as a leading centre for education in low carbon energy technologies.

3.3.15 The proposed accommodation campuses at Bridgwater A and C would result in the loss of existing sporting facilities. The rugby training pitch at Bridgwater C would be relocated and, as explained in Section 1 of this report, commitments are proposed to contribute towards the construction of the Chilton Trinity swimming pool (£250,000) and to invest £500,000 in new or enhanced sports and leisure facilities in Bridgwater, part of which would mitigate the loss of the Bridgwater Sports and Social Club at the Bridgwater A site. EDF Energy has suggested that this money could be spent on enhancing facilities in east Bridgwater. In addition, public access would be provided to the new sports pitches proposed as part of the Bridgwater A accommodation campus.

b) Transport

3.3.16 Given the location and size of Bridgwater in relation to HPC and main road transport links from the M5 motorway, the general area is likely to experience impacts related to traffic flows, pedestrian amenity and severance, as a result of an increase in HGV and bus traffic, and subsequent community impacts related to air quality, noise and vibration and visual amenity.

3.3.17 The construction of the associated developments (at Bridgwater A and Bridgwater C) could contribute to these impacts, although planning permission already exists for the development of the Bridgwater A site and the HPC proposals would principally bring forward the remediation of that site.

3.3.18 The assessment of transport impacts is based on the build-up of highway use and capacity over the construction phase, at intervals (2013 Quarter 3, in the early construction phase) leading up to the peak of the construction phase (in 2016 Quarter 4).

3.3.19 Building up to peak construction, 2013 represents the early construction phase of the HPC Project before all of the associated developments are operational. In terms of highway improvements, the analysis has been undertaken on the basis of only some site preparation works improvements and with improvements at Huntworth roundabout and M5 motorway, Junction 23 being in place. The Somerfield site at Junction 24 would also be in operation as a park and ride and freight management site.

3.3.20 In 2016 all highway improvement measures outlined in the **Transport Assessment** would be in place. Based on workforce and freight movement profiles, the 2016 Quarter 4 is the period when traffic impacts are likely to be at their greatest.

Additionally, the Bridgwater accommodation campuses would be fully occupied leading to peak bus flow to and from the HPC development site.

3.3.21 Once the construction phase of the HPC Project is complete, HPC would be operational and impacts related to on-going operation of HPC have been identified at 2021 when both reactors would be online and the majority of construction works are complete, with a full operational staff on-site. Compared with the peak of construction activity, impacts would be significantly less.

3.3.22 EDF Energy would, however, seek to implement the entire highway improvement package as soon as possible and, therefore, some additional improvement measures may be in place before the assessment period of Quarter 3 2013. In 2016, the assessment assumes that the remainder of the highway improvements proposed by EDF Energy as part of the application for development consent would be in place.

3.3.23 The transport strategy for the HPC Project is explained in full in the **Transport Assessment.** In order to limit the impact of construction traffic from the M5 motorway, two HGV routes have been identified:

- From Junction 23 of the M5 motorway travelling west to Dunball Roundabout, south via the A38 (Bristol Road) to Bridgwater, onto The Drove and Western Way to join the A39 (Quantock Road) at Quantock Roundabout, then travelling west on the A39 towards Cannington and Hinkley Point; and
- From Junction 24 of the M5 motorway (Huntworth Roundabout) and north via the A38 to Bridgwater (Taunton Road) joining the A38 (Broadway) travelling west, on to Cannington and Hinkley Point.

3.3.24 Monitoring would ensure that HGV traffic would be limited to these routes so that there would not be HGV traffic impacts on other routes. These routes would also be the principal bus routes for construction workers to and from Hinkley. Car traffic is expected to be relatively limited because only very restricted parking is to be provided on the HPC development site and workers would be required to use dedicated buses. Nevertheless, some environmental transport-related impacts would remain in Bridgwater as a result of the HPC Project.

3.3.25 In 2013, The Drove, Western Way and the A39 west of Quantock roundabout would experience significant increases in traffic. The Drove, however, runs through industrial areas with virtually no pedestrian activity or adjacent residential properties. For Western Way, the predicted level of HGVs and buses is 893 (2-way daily movements), an increase in HGVs and buses of 559 vehicles per day from the Reference Case. The increase represents an average of 23 vehicles per hour or one every 3 minutes. On A39 west of Quantock roundabout, the predicted level of HGVs and buses is 1,764 (2-way daily movements), an increase in HGVs and buses of 1,139 vehicles per day from the Reference Case. The increase represents approximately one vehicle every minute.

3.3.26 The impact of these increases in traffic flows is assessed in relation to severance, pedestrian delay, pedestrian amenity, driver delay and accidents and safety. Severance is defined as perceived division that could occur within a community when it becomes separated by a major traffic artery and is therefore particularly relevant the consideration of impact on the community. The increases in traffic flow at the above three links are assessed as of **moderate adverse** significance on severance,

minor adverse on driver delay and **minor adverse** on accidents and safety. Due to the increase in HGV and buses on certain links, the impact on pedestrian amenity has been assessed as **moderate adverse**.

3.3.27 The increase from current level in all vehicle daily traffic flows as a result of the HPC Project on these routes in 2013 are 6.9%, 6.7% and 15.9% for The Drove, Western Way and A39 west of Quantock roundabout respectively.

3.3.28 At present the proportion that HGVs represent of the total flow along Western Way is 1.7% which is a low percentage especially for an “A” road (national average is 7%). Even with the addition of HPC HGVs at peak construction (2016) the proportion would increase to 3.7%, which is still a low figure for this type of road.

3.3.29 In terms of pedestrian amenity, at peak construction in 2016, Way and A39 Broadway would experience a daily flow increase of HGVs and buses of more than 100%, resulting in a **moderate adverse** impact, and potentially greater at peak. However the number of days of peak HGVs would be relatively small and the large majority of time the flows would be less than the peak.

3.3.30 By 2016, project-wide mitigation measures and highway improvements would be in place. Junctions where potential safety improvements have been identified are shown below. In addition to the proposed highway improvements EDF Energy propose to offer potential safety enhancements and pedestrian and cycle improvements within Bridgwater that Somerset County Council are progressing as part of their ongoing programme of improvements.

- The A38 Taunton Road/Wills Road Junction;
- Wylds Road/The Drove;
- A38 Bristol Road/A39 Bath Road/The Clink (Cross Rifles Roundabout);
- A38 Taunton Road/Rhode Lane;
- A39 Broadway/A38 Taunton Road;
- A39 Broadway/A372 St John Street;
- A39 North Street/Albert Street; and
- A39 North Street/West Street.

3.3.31 In 2016, The Drove, Western Way, A39 west of Quantock Roundabout and the A39 Broadway would experience significant increases in HGV and buses arising from the peak of construction employment. There are predicted to be 698, 1,022, 1,740 and 849 HGVs/buses (2-way daily flows) on these four links respectively, with the HPC Project. This is an increase from 296, 312, 595 and 460 HGVs/buses on these four links respectively in the Reference Case. This is equivalent to an increase of approximately 135%, 225%, 190% and 85% respectively of Reference Case HGV and bus flows on these four links.

3.3.32 However total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would see a significantly lower increase on all four routes as a result of the HPC Project. The total increase in daily 2-way vehicle trips on each link is approximately 0%, 15%, 4% and 27% for The Drove, Western Way, A39 west of Quantock Roundabout and A39 Broadway, respectively.

3.3.33 The impact of the increase in HGV and bus flows on The Drove and Western Way is considered to be **moderate adverse** and **substantial adverse** for a short stretch of the A39 west of Quantock Roundabout, in terms of severance. The impact in Bridgwater in terms of pedestrian amenity is considered to be **moderate adverse**. The increases in total traffic flows through Bridgwater as a result of the HPC Project are all less than 30%, although HGV flows increase by greater than 30% in some locations. On this basis, the potential impact on safety is assessed as **minor adverse**.

3.3.34 In terms of the other assessment criteria, with the DCO highway improvements in place, the impact is considered to be **negligible**.

3.3.35 In 2021, the increase in HGVs and buses on the above links as a result of the HPC Project significantly reduce. There are predicted to be 427, 634, 1,171 and 679 HGVs/buses (2-way daily flows) on The Drove, Western Way, A39 west of Quantock Roundabout and the A39 Broadway respectively with the HPC Project. This is an increase from 331,343, 643 and 515 HGVs/buses on these four links respectively from the Reference Case. This is equivalent to an increase of approximately 29%, 85%, 82% and 32% respectively of Reference Case HGV and bus flows on these four links.

3.3.36 The impact of the increase in HGV and bus flows on A39 Broadway is considered to be **minor adverse** and **moderate adverse** for A39 west of Quantock Roundabout and Western Way, in terms of severance. The impact in Bridgwater in terms of pedestrian amenity is considered to be **moderate adverse**. The potential impact on safety is assessed as **minor adverse**.

3.3.37 In terms of the other assessment criteria, the increase in total traffic does not meet the relevant thresholds and therefore the impact is considered to be **negligible**.

3.3.38 As in 2013 and 2016, it is relevant that the total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would result in a significantly lower increase of total vehicles on all four routes as a result of the HPC Project. The total increase in daily 2-way vehicle trips Western Way and A39 west of Quantock Roundabout is approximately 5.6% and 12%, respectively. Total traffic flows for The Drove and A39 Broadway improve as a result of the HPC development with total daily traffic flows reducing by -4.5% and -0.2% respectively, in 2021.

3.3.39 Bridgwater is an urban area; nevertheless, some change in character would be experienced as a result of HPC traffic, as described above. This would however only be temporary, throughout the course of the HPC Project, and would not persist following completion of the construction phase, when there would just be operational staff on the site. It is also relevant that the above figures are worst-case, particularly with regard to anticipated bus numbers. Timetables and routes have been developed for modelling purposes for the **Transport Assessment** to assess the worst-case impact that the provision of such services could have on the highway network. As the development progresses, EDF Energy would refine the bus services, routes and timetables to best serve the actual distribution of workers and this should enable the number of bus trips to be significantly reduced.

3.3.40 Notwithstanding the environmental transport-related impacts for certain links in Bridgwater, as described above, the **Transport Assessment** submitted with the application for development consent shows that the package of transport improvements proposed as part of the HPC Project reduces the impact on the highway network in Bridgwater Bridgwater in terms of journey times, junction performance and total network delay to acceptable levels in 2013 and 2016; and provides some benefit to the highway network in 2021.

c) Noise and Vibration

3.3.41 The construction phase of the HPC Project is likely to result in impacts on the local community in terms of temporary traffic- and construction-related noise, and particular concerns have been raised in relation to residential amenity.

d) Traffic Noise Increase

3.3.42 Areas likely to be affected by road traffic noise are along the A39, notably between Cannington and Bridgwater, and North Street and Broadway in Bridgwater, as well as the Northern Distributor Road (NDR). These routes are affected due to their being on the two HGV (and main bus) routes through Bridgwater.

3.3.43 In Bridgwater noise impacts from daytime HGV movements along the NDR are assessed as being of **moderate adverse** significance in 2016. In 2013 and on the other designated HGV route in 2013 and 2016, these daytime impacts are assessed as no more than **minor adverse**.

3.3.44 Where other **moderate and major adverse** impacts have been assessed in Bridgwater these relate to the shorter periods of time associated with early morning and late evening bus movements which have been modelled on robust worst case assumptions. These impacts are limited to the two designated routes for HPC traffic and are on ‘A’ roads which are recognised as the main corridors for traffic through Bridgwater. The absolute noise levels which would arise from HPC related traffic, in Bridgwater, are not predicted, at any point in the construction programme, to breach any statutory limits in relation to road traffic noise.

3.3.45 The associated development sites form part of an overall mitigation strategy to minimise the number of vehicle movements on the highway network associated with the HPC Project. The associated development sites have been designed to ensure that all site workers (excluding minimal office based staff) would use buses to travel to and from the HPC development site. Noise effects may also arise from the construction of the Bridgwater A site. The highest predicted noise levels during the construction phase would occur at the southern boundary of the proposed development site, closest to existing dwellings on Bath Road (south of the existing Bridgwater Sports and Social Club). The significance of impact reduces as works are undertaken further to the north and for properties east of Bath Road as the separation distance increases.

3.3.46 Typical construction and demolition working routines are unlikely to generate levels of vibration at local receptors above which cosmetic damage would be expected to be sustained. Due to the distance to the nearest sensitive receptor (30m) and the level of vibration likely to be caused an adverse impact on residential properties is possible. Adherence to typical construction working hours, during which existing road traffic noise from the A39 Bath Road dominates, would minimise the potential for disturbance. There would be short-term impacts for the nearest properties, therefore, but Bridgwater A is a brownfield site with planning permission for development and any construction activity there is likely to have similar effects.

3.3.47 The construction of the Bridgwater C site would also generate noise which would be perceptible at dwellings on Fairfax Road and Bath Road and at Bridgwater College but the noise levels would not be unexpected for an urban development site.

e) Air Quality

3.3.48 The construction phase of HPC is likely to result in impacts on the local community in terms of temporary reductions in air quality, and particular concerns have been raised in relation to sensitive receptors in and around traffic routes in Bridgwater.

3.3.49 Short-term particulate matter and NO_2 emissions associated with traffic during the construction of both the HPC development site and the majority of the associated development sites is not considered to cause a significant impact on human receptors in Bridgwater during early years (2013) or at peak construction (2016)[1]. In any case, to avoid potential adverse impacts the **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards.

3.3.50 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particle emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**.

f) Landscape and Visual

3.3.51 No adverse impacts of greater than minor significance have been identified on townscape character areas including Sydenham and Bower and North East Bridgwater, Town Centre and Wylds Road as a result of the HPC development.

3.3.52 The effects of the development on local landscape and visual amenity are related to:

- the construction, operational and post-operational phases of Bridgwater A and Bridgwater C leading to impacts in terms of changes in landscape/townscape character, historical and cultural associations, landcover and vegetation and land use / settlement; and
- adverse impacts on visual amenity of number of selected local daytime views as a result of the associated developments.

3.3.53 During operation of the associated developments, planting would be employed to mitigate any adverse impacts, including a screen on the boundary of the Bridgwater A site, along the line of the main western Taunton to Bristol railway, and along the

[1] The worst-case annual mean NO_2 vehicular contributions in the Bridgwater model for the 2021 'with development' scenario are of no greater than medium magnitude. Maximum worst-case vehicular contributions are observed at '86 Bath Road' for the 2021 'with development' scenario for annual mean NO_2. The worst-case ambient concentration value at '86 Bath Road' for annual mean NO_2 for the 2021 'with development' is just below the EU objective threshold and so is predicted to be **moderate adverse**. However, concentration values at the other 43 human receptors are below the EU objective threshold and so are predicted to be either **slight adverse** or **negligible**.

eastern boundary. Planting is proposed within the road verge, further screening views towards the proposed development site from residential properties along the Bath Road.

g) Recreation and Amenity

3.3.54 The nature of the HPC Project would result in temporary impacts on the amenity of users of local recreation facilities currently used by the local community, including the closure and removal of sport facilities at Bridgwater Sports and Social Club, comprising a playing field, a bowling green, and a single storey clubhouse (as a result of Bridgwater A), and Bridgwater and Albion Rugby Football Club training pitch (as a result of Bridgwater C).

3.3.55 Further to this, the construction and operational phases at Bridgwater C would result in an adverse impact in terms of visual disturbance to users of sports and leisure facilities at Bridgwater and Albion Rugby Football Club.

3.3.56 As explained above and in Section 1 of this report, however, a comprehensive package of mitigation measures is proposed by EDF Energy. The net effect of these is that Bridgwater would experience no net loss of recreation, leisure or amenity facilities during the construction period of HPC and would be left with a legacy of improved facilities as a result of the investment of £750,000 proposed in new or improved leisure facilities in the town.

3.4 Summary of Impacts and Mitigation

3.4.1 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Bridgwater has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

3.4.2 This section of the report has focussed on identifying the impacts which the HPC Project is likely to have on Bridgwater. As it is the largest population centre in the vicinity of Hinkley Point C, Bridgwater is forecast to experience some of the most significant impacts of the HPC Project, although these are principally temporary.

3.4.3 Bridgwater also benefits from some of the more significant mitigation proposals which would address those impacts during the construction phase, and in some cases offer positive future benefits in terms of transport and community infrastructure provision. Mitigation and best practice measures would include:

- A series of local education, training, outreach and recruitment initiatives to maximise the opportunity for local people to gain employment in the construction and operation of HPC.
- A Housing Fund has been proposed as “advance mitigation”, i.e. to be used to put in place measures to assist local households and to bring forward additional local accommodation in case an impact does arise when the peak of the construction workforce arrives in the area. EDF Energy’s research suggests that a housing fund of £5 million would be sufficient to create at least 1,000 additional housing opportunities locally.
- Money is to be spent on public realm heritage improvements in the local area. In particular, funds are to be spent against a detailed programme of activity agreed

with the County Council which would see improvements to public realm heritage assets in both Cannington and Bridgwater.

- Investment in traffic calming and pedestrian improvements and Junction improvements in Bridgwater and on the A39 which would leave a legacy of an enhanced transport network in Bridgwater.
- The relocation of the rugby training pitch at the Bridgwater C campus site.
- £250,000 towards the construction of a new swimming pool in Bridgwater.
- £500,000 to provide new playing fields and social club facilities to off set the loss of such facilities at the former Innovia site.
- Investment of £3 million in the existing Energy Skills Centre at Bridgwater College in order to enhance its capacity.
- A public information centre in Kings Square, Bridgwater, to provide a point of contact for the community and visitors to the area who have an interest in the HPC Project.

3.4.4 Every effort has been made to assess and address the potential impacts which the HPC Project would have on the community of Bridgwater. Overall, based on the assessed impacts and proposed mitigation/best practice including implementation and management strategies, and financial contributions, the residual impacts of the project on Bridgwater have the potential to be beneficial, stimulating improvements in supply chain investment and potentially stimulating further low carbon investment. The HPC Project should leave lasting benefits in terms of the local economy, a skilled and trained workforce and lasting improvements in the accommodation market, leisure facilities and the highway network. Perhaps even more importantly, it would bring large numbers of construction and operational jobs to Bridgwater.

4. CANNINGTON

4.1 Introduction

4.1.1 As one of the closest larger settlements to the HPC development site, and on the current transport route from Bridgwater and the M5 motorway to Hinkley Point, Cannington is anticipated to experience a number of effects from the construction, operational and post-operational phases of the HPC Project.

4.2 Context

a) Local Area and Community Impacts

4.2.1 Cannington is a village to the north-west of Bridgwater, and around 8km to the south-east of HPC. The built-up area comprises the majority of the 2,381 population of Cannington Civil Parish (CP) (Census 2001). The population has experienced a low level of growth in recent years, and has an older and ageing population, generally low levels of deprivation and very low levels of unemployment. Cannington was designated a Conservation Area in 1991 and the designation covers the central area of the village, through which the C182 (Rodway), leading to Hinkley, passes.

4.2.2 At Cannington, the A39 passes to the south of the village, connections can be made to the C182 (Rodway) via either High Street to the west of the village, or Main Road through the centre. The C182 (Rodway) connects to north-west to the HPC main development site.

4.2.3 The elements of the HPC Project anticipated to result in impacts on the community in Cannington are:

- the proximity of the HPC development site, and the location of Cannington on strategic transport links from the M5 motorway to Hinkley Point;
- the proposed park and ride site, just to the south of Cannington, which would include two parking areas for workforce and visitors, a bus waiting area, ancillary development and a new access on to the A39; and
- the proposed Cannington bypass, which would run in a north-south direction to the west of Cannington village, commencing at the existing roundabout on the A39 Cannington southern bypass and terminating at the C182 (Rodway) to the north of Cannington.

4.2.4 As such, community impacts are most likely to arise in Cannington as a result of the construction of associated developments, and from the traffic and employment generation linked to the construction phase of the HPC Project.

4.2.5 Cannington has a number of community assets, including public rights of way (PRoW), areas of landscape character, and facilities such as Bridgwater College and Brymore School, which would be directly affected as a result of the proposals.

4.2.6 Indirectly, there could also be effects on local residents and users of community facilities, where amenity levels are affected by adverse impacts of the HPC Project on traffic, visual amenity, noise levels and recreation.

4.2.7 **Figure 27A.4** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

4.2.8 Even with the HPC transport strategy and freight management strategy there would inevitably be an increase in traffic movements (HGVs; buses and cars) on the local network. After careful consideration and consultation EDF Energy has concluded that a bypass around the west of Cannington should form part of the DCO application proposals. This would mitigate the impact of additional traffic and in particular HGVs and buses through the village, once the bypass has been constructed, and leave a lasting benefit for the amenity of the village.

4.2.9 The nature of the HPC Project is such that associated developments are required to support the construction phase – in this case the bypass around the west of Cannington, and a park and ride facility to the south which would provide a location to bring together construction workers from the local area and visitors and transport them to the HPC development site by bus. The park and ride site would be removed once the power station is constructed but the bypass would be retained permanently.

4.2.10 The **Alternative Sites Assessment** describes the sites credentials compared with other sites, whilst the **Consultation Report** describes how the site were selected.

4.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

4.3.1 The Cannington ward cluster (with a population of 7,000 this includes the village of Cannington but also a wider area) is forecast to accommodate around 120 non-home-based construction workers in 2016, when the construction workforce is at its peak. This is equivalent to around 22% of annual new residents, based on the number of new residents observed in the 2001 Census.

4.3.2 Although this is a relatively low proportion of the population, concerns about impacts of non-home-based construction workers on the supply of accommodation, public safety, community cohesion, the provision of services and the capacity of community facilities have been raised in consultation.

4.3.3 The 120 non-home-based construction workers are anticipated to be split fairly equally between types of accommodation (private rented (c. 25), tourist (c. 30), owner-occupied (c. 35) and latent (c. 30)). Using conservative estimates this is identified as being within existing capacity, taking into account turnover and vacancies.

4.3.4 EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The number of workers attracted to seek accommodation in Cannington should be regulated by the available supply. The accommodation office for the HPC Project, however, would have the ability to direct new applicants away from Cannington if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit Cannington and its residents in the event that hardship is being caused.

4.3.5 Similar issues arise in relation to education. Workers resident in Cannington may seek to place their children in the primary school, although only a small proportion of workers are expected to bring children. In 2010/11 the school had room for 175 pupils and had 164 pupils on roll, so spare capacity of 11. In order to head off any potential shortfall in capacity, EDF Energy's proposals described in Section 1 include investment intended to provide new or enhanced classroom facilities in Cannington (and Bridgwater) and a formula for payment towards increasing education capacity further if monitoring identifies further impacts beyond the enhanced capacity. Such improvements would ultimately need to be agreed between the County Council and individual schools.

4.3.6 The wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to leisure impacts, the overall effects on facilities in Cannington are likely to be very small. However, in discussions with the local planning authorities, Cannington has been identified as a sensible location in which to invest part of the mitigation package proposed by EDF Energy. Accordingly, the **Heads of Terms for the Section 106 Agreement** propose an investment of £500,000 towards new or enhanced leisure facilities in the village, which should provide a significant long-term benefit for Cannington residents and those living nearby.

4.3.7 Cannington would also benefit from the Community Impact Fund described in Section 1. £500,000 of the Fund has been "ring fenced" for projects in Cannington. Those projects are to be suggested by the local community as projects which would add to the local quality of life. Again, this should be a significant benefit for the village.

4.3.8 EDF Energy is also committed to invest in training and education facilities in order that local people can gain the skills and qualifications to work on the HPC Project both in the construction phase and in the completed development. The **Economic Strategy**, and the **Construction Workforce Development Strategy** which is appended to it set out a series of actions and investments which EDF Energy would undertake. This includes investment of £1.5 million in a Construction Skills Centre in partnership with Bridgwater College at Cannington.

b) Transport

4.3.9 Given the location of Cannington in relation to the HPC development site and main road transport links from the M5 motorway and population centres such as Bridgwater and Taunton, the general area is likely to experience impacts related to increased traffic flows, severance, and an increase in HGV and bus frequency, and consequent community impacts related to air quality, noise and vibration and visual amenity. Cannington would experience greater impacts than any other community because of its location on the C182 (Rodway), which provides the principal access north to Hinkley Point.

4.3.10 Two associated developments are proposed in Cannington, including the bypass and around the west of the village and park and ride facility to the south. These would be constructed early in the construction programme to facilitate the construction of HPC. In particular, the bypass would direct construction traffic away from being routed through the centre of Cannington.

4.3.11 The construction of the associated development sites at Cannington park and ride and Cannington bypass, together with the location of the HPC development site nearby would bring impacts of their own but both developments would reduce traffic through Cannington by intercepting car traffic and converting it to buses and by diverting traffic around Cannington. These facilities together would reduce both traffic and associated noise and other impacts that would otherwise affect the High Street and southern part of the C182 (Rodway).

4.3.12 The assessment of transport impacts is based on the build-up of highway use and capacity over the construction phase, with specific assessments made at 2013 Quarter 3, in the early construction phase, and in 2016 Quarter 4 at the peak of the construction activity.

4.3.13 In 2013, construction on the HPC development site would have commenced, but the Cannington bypass would not be completed at this stage. This, therefore, represents the worst-case impacts on Cannington.

4.3.14 In 2016 all highway mitigation measures are assumed to be in place, including the Cannington bypass. Based on workforce and freight movement profiles, 2016 Quarter 4 is the period when general traffic flows are likely to be at their greatest.

4.3.15 HPC would commence operation in 2021 at which pint the main construction works would be complete by 2021. HPC would have an operational life of 60 years.

4.3.16 In Cannington, significant increases in HGV and bus flows on High Street and C182 (Rodway), south of the bypass, are anticipated in 2013. There is also an anticipated impact on the A39 west of Quantock roundabout. More details of the assessment are contained in **Volume 2, Chapter 10** of the **Environmental Statement**.

4.3.17 The impact of these increases in traffic flows is assessed in terms of severance, pedestrian delay, pedestrian amenity, driver delay and accidents and safety. Severance is defined as perceived division that could occur within a community when it becomes separated by a major traffic artery and is therefore particularly relevant the consideration of impact on the community. The most significant impact is the impact on High Street and C182 (Rodway) prior to the opening of the bypass. The **Transport Assessment** estimates that daily vehicle flows would increase by 1,391 vehicles or 64% of the existing flow. A significant proportion of that flow would be buses and HGVs. Limits are proposed to prevent more than 500 HGV movements per day on average over a quarter but with a daily flexibility up to 750 movements within that overall average. There would also be significant movement of buses carrying construction workers - both before the first principal shift which starts at 07:00 and after the last principal shift which finishes at 22:00. C182 (Rodway) and High Street are predicted to experience **major adverse** impacts, in terms of severance.

4.3.18 In terms of pedestrian amenity, the magnitude of impacts is considered substantial; however the proposed improvement scheme in Cannington would improve the pedestrian environment by creating wider footways, and improved crossing facilities and the impact is therefore predicted to be **moderate adverse**. The potential impact on safety is assessed as **minor adverse**, taking into account the proposed pedestrian improvements in the village. In terms of driver delay, the impact in 2013 is predicted to be **minor adverse**. The impact on pedestrian delay is predicted to be **negligible**.

4.3.19 EDF Energy recognise the impact that traffic travelling through Cannington would have and have therefore included provision of the Cannington bypass within the DCO application proposals. However, given the land and other requirements it is not possible to implement the bypass before DCO consent. Therefore the impact of traffic through Cannington would occur for a short period of the HPC development site construction phase. After the construction of the bypass, traffic levels would fall to less than they are currently in Cannington.

4.3.20 Recognising the increases of traffic EDF Energy has proposed traffic management measures within Cannington which would be implemented as part of the Site Preparation Works. These works would control traffic and improve the pedestrian environment, and include (outlined in detail in **Chapter 16** of the **Transport Assessment**):

- a new footway to the northern edge of High Street, opposite Clifford Park;
- provision of skid-resistant surfacing;
- revised parking and waiting restrictions;
- a new puffin crossing at High Street;
- provision of tactile paving and widening of existing uncontrolled crossing at junction of Church Street and High Street;
- new speed restriction signs enforcing existing speed restrictions;
- new zebra crossing on C182 (Rodway) before junction with Toll House Road; and
- tactile paving at junction of C182 (Rodway) and Toll House Road.

4.3.21 Notwithstanding these measures, the net effect on Cannington during the early years period before the bypass is complete would be adverse – with **moderate to major** adverse effects on amenity depending on the location:

4.3.22 In terms of severance, in the A39 to the south and south-east would experience increased HGV and bus flows of over 90% as these links are on HGV/bus routes to HPC. As such, this is considered a **moderate adverse** impact (although for the affected sections of the A39, these areas are rural in nature with virtually no pedestrian activity or residential properties). Additionally, no such vehicles would be permitted on Main Road therefore no increase is anticipated at that location.

4.3.23 On Cannington High Street, re-siting of the existing zebra crossing near the Memorial Junction and its conversion to a pelican crossing, and the addition of a new crossing on the C182 (Rodway) close to Bridgwater college would in fact lead to a **moderate beneficial** impact on pedestrian delay.

4.3.24 In terms of pedestrian amenity, substantial increases in daily flow rates are anticipated on highways in Cannington, although as the proposed improvement scheme in Cannington would improve the pedestrian environment by creating wider footways, and improved crossing facilities the significance of the impact is considered **moderate adverse.**

4.3.25 In recognition of the short-term effect on the village, the **Heads of Terms for the Section 106 Agreement** propose that a sum of up to approximately £200,000 is made available for public realm improvements in Cannington and Bridgwater. Work undertaken with the Somerset County Council and Sedgemoor District council (SDC) has identified heritage assets in the village which could be restored or enhanced in order to offset the adverse impacts of increased traffic flows through the Conservation Area.

4.3.26 Once the bypass is complete, there would be a beneficial impact compared to existing conditions within Cannington. All construction traffic (including park and ride buses and HGVs) would be required to use the bypass, with the exception of some buses which would be routed through Cannington to pick who workers who live in the village, if required, rather than local roads through the village. It is proposed that the Cannington bypass would remain as permanent legacy, so that operational traffic and traffic associated with maintenance outages at HPC would also avoid passing through the village.

4.3.27 At peak construction in 2016, both Main Road and C182 (Rodway) (south of Cannington bypass) would experience reductions in general daily traffic flow of between 30% and 60% as a result of the Cannington bypass. However, the A39 south-east and south of Cannington would still experience **moderate adverse** impacts, in terms of severance, as a result of being direct HGV/bus routes to the site, and **minor adverse** impacts in terms of accidents and safety. **Negligible** impacts are predicted with regard to all other environmental-related transport criteria.

4.3.28 The construction and operation of the bypass itself could create impacts on the operation of Brymore School, particularly changes to its existing access and severance from the community, and loss/severance of agricultural land used by the school (see the **Consultation Report** for details).

4.3.29 Taking into account design features of the proposed development, including a toucan crossing close to the access to Brymore School to enable pedestrians to cross safely and the inclusion of a cattle crossing and the use of acoustic bunds to mitigate noise impacts, the impacts in relation to severance from agricultural land and potential traffic safety impacts on pupils is considered to be mitigated.

c) Noise and Vibration

4.3.30 The construction phase of HPC is likely to result in impacts on the local community in terms of temporary traffic and construction-related noise, and particular concerns have been raised in relation to residential amenity in terms of:

- daily road traffic noise impacts between the A39 and the HPC site at specific sensitive areas;
- noise from construction works related to the Cannington bypass and Cannington park and ride facility at residential properties including Knapp Farm and Withiel Farm, Rothay Cottage, and neighbouring properties; and
- disruption to amenity of users of PRoWs close to the associated development sites and resulting from traffic increases.

4.3.31 In addition, Construction of the Sandford Corner roundabout, a highway improvement scheme that would replace the existing priority junctions, is expected to last a maximum of six months. The closest noise sensitive receptor to this proposed work is a single residential dwelling approximately 25m to the east and southeast, which is anticipated to experience noise level of 73dB $L_{Aeq,12h}$ (excluding ambient noise level). The impact of these short-term activities is predicted to be of **moderate adverse** significance.

4.3.32 In 2013, the daily road traffic noise impacts would be most significant between the A39 and the HPC development site (through Cannington High Street and on the C182 (Rodway) prior to the opening of the proposed Cannington bypass, resulting in a **major adverse** impact.

4.3.33 The proposed Cannington bypass would reduce the predicted noise impacts from HPC construction traffic in Cannington village in 2016. As a result of the proposed bypass, **beneficial** impacts are predicted along the route through Cannington.

4.3.34 In recognition of the adverse noise impacts which have been assessed prior to the opening of the Cannington bypass, the consideration that some of the adverse impacts occur late in the evening and in the early morning and taking account of the existing character of the affected areas, EDF Energy proposes to offer a Noise Insulation Scheme to the most affected residents in Cannington. The Noise Insulation Scheme would offer measures including window glazing, and acoustic ventilation.

4.3.35 The construction of the associated developments would lead to temporary noise and vibration impacts at Knapp Farm and Withiel Farm (**major adverse** impact), Rothay Cottage, and neighbouring properties (**moderate adverse** impact), residential properties close to the C182 (Rodway) (**moderate adverse** impact), and in terms of the amenity of users of public footpaths within 300m of the proposed development (**minor adverse** to **moderate adverse** impacts). In relation to the Cannington park and ride site, these impacts are primarily as a result of the immediate proximity of the site to public rights of way (one is located within the site, although it is not physically affected). Such impacts would be temporary and should be viewed in the context of the transient nature of users of the footpaths. In this case, the impact has also been limited as far as possible through the provision of a 2 metre bund to the west of the site.

4.3.36 The design of the proposed Cannington bypass includes 2 metre high acoustic bunds with vegetated slopes along parts. The construction of these bunds would be undertaken at the earliest possible stage during the earthworks. The bunds would screen the closest residential dwellings to the proposed development from the subsequent phases of construction works.

d) Air Quality

4.3.37 The construction phase of the HPC Project is likely to result in impacts on the local community in terms of temporary reductions in air quality, and particular concerns have been raised in relation to locations in and around Cannington. The key impacts relate to:

- secondary effects of increased traffic in the local area; and
- impacts related to dust and particulate matter generated from construction activities at the associated development sites.

4.3.38 Specifically, properties likely to experience **moderate to major** adverse impacts related to the construction of the Cannington bypass have been identified near to the site boundary and along the affected road network (15 Withiel Drive; 22 Withiel Drive; Brymore Lodge; Brymore Lodge (external buildings); Brymore Secondary Technical School; Hensfield Farm; Chad's Hill; Knapp Farm; Chad's Hill; Pavilion; 58m from (C182) Rodway; Putnell Barn; Rothay; High Street; Withiel Barn; Withiel Drive; Withiel Farm; Withiel Drive), along with users of PRoWs.

4.3.39 The closest homes which could experience **moderate** adverse impacts as a result of the Cannington park and ride facility include those near to the site boundary and along the affected road network (32 Brownings Road).

4.3.40 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate matter emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**. As a result of the implementation of control methods, there are predicted to be **no significant residual impacts** related to the construction, operational and post-operational phases of the associated development sites themselves.

4.3.41 In terms of impacts arising from increased traffic flows, for all assessed pollutants, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on human receptors for the 2013 and 2016 ‘with development’ scenario is local, adverse, direct, likely and medium-term but temporary. The impact on the human receptor locations for all assessed pollutants is determined to be **not significant**.

4.3.42 The purpose of the proposed Cannington bypass is to minimise adverse effects on the local highway network, particularly through the centre of the village, during the HPC construction phase. There will be a benefit with respect to air quality associated with the operation of the Cannington bypass within the village, as HPC development traffic will be routed away from the centre of Cannington. In addition some of the non-HPC traffic that would have previously used the existing roads through Cannington will in preference travel along the bypass. The ‘with development’ concentration values for annual mean NO_2 in the Cannington model are all well below the EU threshold levels and so are predicted to be **minor adverse**. Their impact on the human receptor locations is therefore **not significant** during the ‘worst-case’ scenario (peak construction, 2016).

e) Landscape and Visual

4.3.43 The effects of the development on the landscape and visual amenity are related to:

- a change of land use and break in landscape connectivity as a result of the Cannington bypass, leading to **major adverse** impacts on the visual amenity of users of public rights of way (BW5/20, BW5/8, BW5/17, PRoW BW5/7 and BW7/4) and identified viewpoints; and
- **moderate to major adverse** impacts resulting from the Cannington park and ride facility, which would change the local landscape by adding built elements including roads, small buildings, lighting and CCTV columns and security fencing and additional vehicle movements.

4.3.44 The moderate and major significant impacts at the construction, operational and post-operational (i.e. removal/restoration) phase of Cannington park and ride are confined to a small area close to the site. The site is currently in agricultural use and the temporary change of use to a park and ride site represents a significant change to the landscape character and inevitable landscape impacts. The mitigation provided inherent within the design has aimed to reduce this impact as far as possible and achieve an attractive and appropriate landscape setting to the proposal.

4.3.45 The assessment of the potential impact to the visual amenity of leisure and recreation facilities within the local area during the construction phase of the park and ride facility concludes that there could be a **moderate adverse** impact at Cannington Cemetery and the sports pitch by Shark's Lane.

4.3.46 The design of the proposed bypass includes measures to mitigate the impacts on landscape and visual amenity within the design. These include screen planting, highway boundary planting of hedgerows with trees and ecological mitigation measures. Acoustic bunds would also provide further visual screening of the bypass when it is complete and operational.

f) Recreation and Amenity

4.3.47 The nature of the HPC Project would result in temporary impacts on the amenity of users of recreation features currently in use by the community – this includes the PRoW BW5/8 and local facilities including Cannington Cemetery and the sports pitch by Shark's Lane. Throughout the process, consultation has been undertaken with SCC's Rights of Way Officers, The Ramblers Association, and users of the PRoW network.

4.3.48 The impacts identified are most specifically related to direct impacts of connectivity arising from the severance and obstruction of PRoW BW5/8 that is crossed by the proposed Cannington bypass.

4.3.49 PRoW BW5/8, which connects southern Cannington with other local settlements (Combwich, Otterhampton and villages to the east via joining with other PRoWs) would be bisected by the route of the bypass construction works, which would result in the obstruction of this PRoW.

4.3.50 A diversion route would be provided for users of PRoW BW5/8 to gain access across the route of the bypass during the construction phase. The diversion would either cross the construction site or divert around the area under construction. This would ensure that the right of passage is maintained and that connectivity to the PRoW network to the west from Cannington or west into Cannington would be assured, leading to a **minor adverse** residual impact. After the opening of the bypass the traffic flows on the bypass are predicted to be such that the PRoW can be reopened.

4.3.51 There would also be indirect amenity impacts on users of public rights of way in the immediate vicinity of the Cannington park and ride site, primarily arising from predicted noise and visual impacts identified during the course of construction, operation and post-operation. These should be viewed in the context of the transitory nature of the users of the public rights of way and the relatively limited sections of footpath that are likely to be affected.

4.4 Summary of Impacts and Mitigation

4.4.1 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Cannington has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

4.4.2 This section of the report has focussed on identifying the negative impacts which the HPC Project is likely to have on Cannington. Because of its location on the road network, Cannington is forecast to experience some of the most significant impacts of the project, although these are principally limited to the short-term period up to the opening of the Cannington bypass. Partly as a result, Cannington also benefits from some of the more significant mitigation proposals, including:

- the long-term benefit of a permanent village bypass;
- a Noise Insulation Scheme for properties most affected by short-term traffic noise;
- investment in traffic calming, public realm and pedestrian improvements;
- potential investment in the village primary school;
- £500,000 to be spent on leisure facilities in the village;
- at least £500,000 to be spent on community backed projects to enhance the quality of life of the local community; and
- £1.5 million towards a Construction Skills Centre in Cannington.

4.4.3 As a result the principal impacts that the HPC Project may be likely to have on Cannnigton have been mitigated where practical. The village is well placed for its residents to benefit from the extensive training and employment opportunities that would be available as a result of the HPC Project.

5. OTTERHAMPTON

5.1 Introduction

5.1.1 Otterhampton CP is located to the south-east of Hinkley Point, and comprises the village of Combwich as the main population centre. Although the village is relatively small, Combwich is anticipated to experience a number of effects from the HPC Project, mostly resulting from the proposed Combwich Wharf refurbishment and extension and the construction of a new temporary freight laydown facility which is proposed as one of the associated developments in the HPC Project. Additionally, there would be increased traffic flows on the C182 (Rodway) from Cannington. Combwich is also close to Hinkley Point and so it could become an attractive place for construction workers to seek accommodation.

5.2 Context

a) Local Area and Community Impacts

5.2.1 Otterhampton Parish is largely comprised of rural, agricultural land, with the majority of its 1,335 population located in Combwich, which has around 550 dwellings. The population of the village has an older profile, and has been growing in recent years. The area supports relatively few jobs (around 160), although there is a low level of unemployment among residents, and low levels of deprivation. The village has an attractive, close knit character and it adjoins the River Parrett.

5.2.2 At Combwich, the C182 (Rodway) from Cannington passes to the west of the village and continues on to Hinkley Point. Once operational, the Cannington bypass would join the C182 (Rodway) just south of Stradling's Hill, to the north of Cannington and south of Combwich, and would form a key route to the HPC development site for HGVs and buses.

5.2.3 EDF Energy operates an existing Roll-on Roll-off port facility at Combwich Wharf on the River Parrett. This facility is periodically used by National Grid and EDF Energy for the transport of AILs to the existing Hinkley Point Power Station Complex. EDF Energy owns a private access road which connects Combwich Wharf to the C182 (Rodway), passing to the south of the village (the Combwich Wharf access road).

5.2.4 The community at Combwich are expected to be impacted by the HPC Project as a result of the following:

- the nearby location of the HPC development site;
- the location of Combwich on strategic transport links from the M5 motorway, via Bridgwater and Cannington, to Hinkley Point;
- impacts relating to the construction and operation of the proposed Combwich Wharf refurbishment and extension and the new, temporary freight laydown facility plus the deconstruction of the freight laydown facility and its restoration to agricultural land The proposed development at Combwich Wharf would enable its continued use for the import of AILs and of other bulky construction goods during the construction phase for the HPC Project and thereafter to support its operation. The freight laydown facility would store goods received principally via Combwich

Wharf pending their onward transportation to the HPC development site. Priority would be given to use of the freight laydown facility for the storage of goods arriving via Combwich Wharf but it could also be used to hold general construction goods arriving by road when there is spare capacity and when storage space is not available at the HPC development site. Combwich Wharf would be retained in its refurbished state to support the operation of HPC and would be used at similar levels as currently (up to twice a year). The freight laydown facility would be removed once the construction of HPC has been completed and the land restored to agricultural land; and

- traffic generation associated with the construction, operational and post-operational phases of Combwich Wharf and the freight laydown facility and general traffic associated with the construction of HPC which would use the C182 located a short distance to the west of Combwich village.

5.2.5 Long-term, Combwich has a number of community assets, including the Combwich Motor Boat and Sailing Club (CMBSC). The club's facilities, which are located at Combwich Wharf and which are leased from EDF Energy, include clubhouse buildings, one slipway, pontoon and mooring and berthing points. The area around Combwich Wharf is currently in public usage for the mooring of boats.

5.2.6 Indirectly, there would also be adverse effects on local residents and users of PRoWs that cross and run close to the site, where noise, visual and recreational amenity levels are likely to be affected by adverse impacts resulting from the proposed development.

5.2.7 **Figure 27A.5** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

5.2.8 The refurbishment and extension of the existing Combwich Wharf facility is an important element of the commitment within EDF Energy's transport strategy to maximise the use of the sea to bring construction materials to the HPC site.

5.2.9 The proposals would involve the demolition of redundant features and the creation of new berthing facilities including an Abnormal Loads Quay and a Goods Wharf) in addition to modifications to the berthing bed within the River Parrett. This would be a permanent facility which would continue to be used by the National Grid and EDF Energy during the operation of HPC (see **Volume 7, Chapters 2** to **5** of the **Environmental Statement** for further details). Combwich Wharf has been selected as the location for this facility as it is the closest existing such facility to Hinkley that is available and which can be modified to meet the requirements for AIL deliveries to support the construction of HPC. The temporary jetty at the HPC development site can not be used to receive AIL deliveries as it has not been designed for this purpose and it is too exposed. Combwich Wharf is more sheltered and better suited to receiving AILs (see the **Alternative Site Assessment** appended to the **Planning Statement** for more details).

5.2.10 The proposed development would also include provision of a new, temporary freight laydown facility in an area to the south of Combwich village for the handling and storage of AILs and bulky construction goods before they are transported to the HPC development site (see **Volume 7, Chapters 2** to **5** of the **Environmental Statement** for details).

5.2.11 The new freight laydown facility is proposed to be constructed in an area very close to Combwich Wharf. The origin for many of the AILs means that they need to be transported long distances by sea with sailings booked many months in advance. Sailings may be subject to fluctuation due to adverse weather conditions. In recognition of this, and due to space constraints at the HPC development site, it is proposed to provide a holding area for AILs at Combwich. As there is no laydown area available at Combwich Wharf itself, a laydown facility in close proximity to Combwich Wharf would provide a degree of contingency against any supply disruption before AILs are transported to the HPC development site. At times when the freight laydown facility would not be used for AILs i.e. where limited or no AIL are delivered to Combwich, the available area would be used in the short-term for storing other construction items.

5.2.12 Use of the laydown would be prioritised for water-borne deliveries arriving at Combwich Wharf. Any surplus storage areas would be used to store road borne deliveries where practicable.

5.2.13 The **Alternative Sites Assessment** describes the site's credentials compared with other sites, whilst the **Consultation Report** describes how the site was selected.

5.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

5.3.1 Combwich falls within the wider Cannington ward cluster identified in **Volume 2**, **Chapter 9** of the **Environmental Statement**. The Cannington ward cluster (the population of which is predominantly made up of the Cannington urban area) is expected to accommodate 120 non-home-based construction workers in 2016, when the construction workforce is at its peak. This is equivalent to around 22% of annual new residents, based on the number of new residents observed in the 2001 Census.

5.3.2 In particular, impacts may arise relating to the capacity of tourist and private rented accommodation sectors, and in terms of the capacity of local schools, particularly if the level of non-home-based construction workers exceeds the 'central scenario' outlined in **Volume 2**, **Chapter 9** of the **Environmental Statement**. The central scenario is based on a workforce profile at peak construction of 5,600 construction workers on the HPC development site and associated development sites combined, of which 66% would be 'non-home-based' i.e. requiring short-term accommodation. In the wider Cannington ward cluster, based on functions of existing supply of accommodation, cost of accommodation and distance to the HPC development site, the 120 non-home-based construction workers are anticipated to be split fairly equally between accommodation sectors (private rented (around 25), tourist (around 30), owner-occupied (around 35) and latent (around 30)).

5.3.3 Based on the size of Combwich village, only a small proportion of these 120 non-home-based construction workers would be expected to live in Combwich.

5.3.4 Although this is a relatively low proportion of the population, concerns about impacts of non-home-based construction workers on public safety, community cohesion, the provision of services and the capacity of community facilities have been raised by the local community.

5.3.5 In the Cannington/Combwich area, at a conservative estimate there is capacity to accommodate this demand in existing vacant bedspaces, although if non-home-based construction workers exceed the central scenario (as modelled and assessed in **Volume 2**, **Chapter 9** of the **Environmental Statement**), capacity issues could arise.

5.3.6 Potential impacts would be mitigated through the workforce or accommodation management measures and contributions outlined in Section 1 of this report. The number of workers attracted to seek accommodation in Cannington/Combwich should be regulated by the available supply. The accommodation office for the HPC Project, however, would have the ability to direct new applicants away from the Cannington and Combwich area if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit Cannington/Combwich and its residents in the event that hardship is being caused.

5.3.7 Similar issues arise in relation to education. The few workers resident in Combwich could seek to place their children in the primary school in Combwich (Otterhampton Primary School) or nearby Cannington (Cannington Church of England Primary School), although only a small proportion of workers are expected to bring children. In 2010/11 the Cannington Primary School had room for 175 pupils and had 164 pupils on roll, so spare capacity of 11. Otterhampton Primary School currently has only three surplus places. Local schools currently have spare capacity but, in order to head off any potential shortfall in capacity EDF Energy’s proposals described in Section 1 include investment in new or enhanced classroom facilities in Cannington (and Bridgwater) and a formula for payment towards increasing education capacity further if monitoring identifies further impacts beyond the enhanced capacity.

b) Transport

5.3.8 At Combwich, the C182 (Rodway) from Cannington passes to the west of the village and continues on to Hinkley Point. Once operational, the Cannington bypass would join the C182 (Rodway) just south of Stradling’s Hill, to the north of Cannington and south of Combwich, and would form a key route to the HPC development site for HGVs and buses.

5.3.9 The Combwich Wharf access road provides direct access to the C182 (Rodway) from Combwich Wharf which means that traffic can avoid going through the village. During the HPC construction period, there would be a significant increase in traffic on the C182 (Rodway). Whilst this is unlikely to impact directly on Combwich residents, the C182 (Rodway) is the principal road used for journeys to and from the village. Transport impacts on the C182 (Rodway), to the north of Cannington, are also indicative of the conditions on the C182 (Rodway) to the west of Combwich and are summarised in this report under transport impacts at Storgursey, in Section 2.0, and repeated below.

5.3.10 The scale of the increase in HGVs and buses on the C182 (Rodway), to the north of proposed Cannington bypass, in 2013, during the early construction phase of the HPC power station, is predicted to increase from 206 HGVs/buses (2-way daily flows) in the Reference Case (existing flows, plus committed development plus background growth) scenario to 1,483 HGVs/buses with the HPC Project (including the mitigation package described above). The total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would result in a*n* increase of 25.9% in all vehicles on the C182 (Rodway) to the north of the proposed Cannington bypass.

5.3.11 In 2016, the 2-way daily flows at the same assessment point are predicted to be 1,698 HGVs/buses with the HPC Project, an increase from 246 HGVs/buses in the Reference Case. This is equivalent to an increase of approximately 590% of existing HGV and bus flows on the C182 (Rodway), to the north of the HPC development site. The above figures include existing and future road traffic associated with Combwich Wharf and is considered to be representative of the conditions likely to be experienced at the C182 (Rodway) to the west of Combwich in 2016, when Combwich would be operational and there would be regular HGV movements between the Combwich freight laydown facility and the HPC development site. However total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would result in a much lower increase of 24.1% in all vehicles on the C182 (Rodway) to the north of the proposed Cannington bypass.

5.3.12 In 2021, the 2-way daily flows on the C182 north of the bypass are predicted to decrease to 773 HGVs/buses with the HPC Project, an increase from 218 in the Reference Case. This is equivalent to an increase of approximately 300% of existing HGV and bus flows on the C182 (Rodway), to the north of the HPC Project. Again total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would see a far lower increase of 15.2% on the C182 (Rodway) to the north of the proposed Cannington bypass.

5.3.13 The impact of these increases in traffic flows is assessed in terms of severance, pedestrian delay, pedestrian amenity, driver delay and accidents and safety. Severance is defined as perceived division that could occur within a community when it becomes separated by a major traffic artery and is therefore particularly relevant the consideration of impact on the community. The increases described above with regard to the C182 (Rodway), to the north of proposed Cannington bypass, in 2013, 2016 and 2021, is considered to be **moderate adverse** in terms of severance. In terms of the other assessment criteria, the increase in total traffic does not meet the relevant thresholds and therefore the impact is considered to be **negligible,** with the exception of driver delay, which is considered to be **minor adverse** in 2013.

5.3.14 Nevertheless, the character of the C182 (Rodway) to the west of Combwich would experience a significant change as a result of HGVs and buses associated with the HPC Project. This would however only be temporary, throughout the course of the HPC Project, and would not persist following completion of the construction phase, when there would just be operational staff on the site. It is also relevant that the above figures are worse case, particularly with regard to anticipated bus numbers. Timetables and routes have been developed for modelling purposes for the **Transport Assessment** to assess the worst-case impact that the provision of such services could have on the highway network. As the development progresses, EDF Energy would refine the bus services, routes and timetables to best serve the actual distribution of workers and this should enable the number of bus trips to be significantly reduced.

5.3.15 The principal mitigation proposed is the transport strategy itself, with its commitment to the use of the sea, the limitation of car parking and the management of HGV flows to reduce their number during the peak periods. In addition, to address the predicted effects on the C182 (Rodway) the following measures are proposed:

- Speed restrictions on the C182 (Rodway);
- A horse crossing at Faringdon Hill Lane to ensure the ability to cross the C182 (Rodway) safely at the busiest times for pedestrians and riders.

c) Noise and Vibration

5.3.16 An assessment has been undertaken of the potential noise and vibration impacts that might arise during the construction, operational and post-operational phases of Combwich Wharf and the freight laydown facility at the nearest residential dwellings, as well as from local amenity and recreation facilities. The construction phase for the refurbishment and extension of the wharf is likely to take up to 12 months (Q1 2013 to Q1 2014).

5.3.17 The construction of the freight laydown facility is also likely to take up to 12 months (Q1 2014 to Q1 2015). The normal hours of work for the construction of the proposed development would be Monday-Friday 07:00 to 19:00 and Saturday 07:00 to 13:00. In the operational phase, the freight laydown facility would be in use between 07:00 and 20:00 Monday to Friday and between 08:00 and 18:00 at weekends. Restricted operational hours and good working practices, including the operation of plant and machinery are the subject of proposed planning controls. Unloading of both AILs and general construction goods deliveries would be restricted to 07:30-18:30 seven days per week.

5.3.18 All AIL and general construction goods deliveries to Combwich Wharf would require a minimum 4.5m neap spring tide. Due to the specific tidal requirements, the arrival and departure of vessels to Combwich Wharf would be unrestricted and would occur at any time, 24 hours per day, seven days per week. AIL deliveries, which rely on a low tide for unloading, would need to be appropriately timed such that the low tide would fall within the specified unloading hours. In circumstances where arrivals occur outside of the specified unloading hours, the contractor would not be permitted to commence unloading until 07:30 the next day. During the operational phase, the freight laydown facility would be in use between 07:00 and 20:00 Monday to Friday and between 08:00 and 18:00 at weekends, Bank and Public Holidays.

5.3.19 The highest predicted noise levels at nearby residential dwellings would occur during the Combwich Wharf refurbishment and extension works. Using a conservative assessment, with all plant assumed to be working at the closest point, the impact of these short-term activities is predicted to have a **moderate adverse** impact on the closest residential receptors at ‘No 24 Riverside’ and ‘No 62 Estuary Park’.

5.3.20 A significant noise impact is predicted at CMBSC during the Combwich Wharf refurbishment and extension. This is associated primarily with the demolition works and is assessed as being of **moderate adverse** significance.

5.3.21 The predicted operational impacts can be separated between the two main proposed uses. The key activities during the operational phase that may cause noise impacts are:

- Refurbished and extended Combwich Wharf facility, comprising;

  - movement and berthing of ships or barges; and
  - un-loading of heavy plant and equipment.
- Freight laydown facility, comprising;
  - loading and unloading operations; and
  - HGV movements on the site.

5.3.22 At the nearest properties on Riverside and Estuary Park, high magnitude noise levels are predicted during AIL and construction goods vessel arrivals and departures, daytime AIL unloading operations and unloading of other construction goods cargo at Combwich Wharf, and their transfer to the freight laydown facility. The impact of these operations is assessed as being of **major adverse** significance.

5.3.23 In recognition of the adverse noise impacts which have been assessed, the fact that some of the adverse impacts would occur at night and in the early morning due to tidal requirements, and taking account of the relatively rural character of the affected areas, EDF Energy propose to offer a Noise Insulation Scheme to the most affected residents closest to Combwich Wharf.

5.3.24 The proposed development includes proposals which are designed to reduce the impacts of noise upon sensitive receptors. These proposals include the construction of a noise bund on the north-west boundary of the proposed freight laydown facility and the erection of an acoustic fence to the west of the Wharf.

5.3.25 Restricted construction and operational hours and adopting best working practices as set out in the **Environmental Management and Monitoring Plan** and **Noise and Vibration Management Plan** would also ensure that adverse imapcts are minimised wherever possible.

d) Landscape and Visual

5.3.26 The activities which are anticipated to have an impact at the construction phase would primarily be associated with the construction of the laydown facility to establish the platform level, attenuation ponds and noise and flood bunds involving the movement of large vehicles. This phase of work is assessed as **moderate adverse**. A **major adverse** impact would also be anticipated at Combwich harbour during the construction phase of the wharf works. During the operational phase the impact would primarily be associated with the arrival of shipping and the associated movement of vehicles transporting goods and the general off-loading activities, and this would result in a **major adverse** impact.

5.3.27 The proposed development site is located about half way along the Parrett Riverscape local character area, and close to Combwich Village and Harbour local character area. The elevated levee, part of the Parrett Riverscape, that runs along the north-east boundary of the freight laydown facility, gives clear views over this part of the site. The impact on the Parrett Riverscape character area as a whole is assessed as of **moderate adverse** significance, although proposed increases in activity on the River Parrett would not be out of character with the current use of the river. A **major adverse** impact would also be anticipated at Combwich Village and Harbour during the operational phase.

5.3.28 The proposed development would have an impact on the River Parrett Trail where it adjoins the freight laydown facility and the footpath along the levee on the opposite bank of the River Parrett. During the construction phase this would be associated with the refurbishment and extension of Combwich Wharf and the establishment of the platform for the freight laydown facility. These operations would involve the movement of large vehicles and machinery. The impact is assessed to be **moderate adverse**. During the operational phase the impact at the Wharf would be associated with the arrival and the unloading of the AILS and vessels and the associated movement of vehicles along the access road. At the freight laydown facility the impact would be associated with the presence of the site itself in a previously agricultural location with associated fencing, lighting infrastructure and stored material and large vehicles the impact is assessed as being of **moderate adverse** significance.

5.3.29 The proposed development would have the greatest impact on the visual receptors at the harbour and immediately surrounding roads, paths and residential properties. There would also be views from the levee, immediately opposite the Combwich Wharf on the opposite bank of the River Parrett, but little visual impact beyond this, as the levee screens most ground level views.

5.3.30 EDF Energy carefully considered the design of the freight laydown facility in order to minimise its impacts on the countryside and on Combwich. The design of the proposed Combwich development has been refined with the benefit of feedback from consultees and through an understanding of the character and visual structure of the landscape as well as the functional and operational requirements of the proposed development.

5.3.31 The proposals aim to create a strong landscape setting which is in character with the surrounding landscape and which can be removed at the end of the operational phase of the freight laydown facility. The landscape strategy for the wharf and the laydown area seeks to respond to the character of the area and to complement the ecological objectives of the project. Through the use of appropriate planting, the landscape strategy aims to screen ground level activities as much as possible from key views to the north from the village and nearby Public Rights of Way (PRoW). This includes:

- visual screen planting in the form of mixed native planting of species around the laydown area to screen views from the River Parrett Trail PRoW and long views from the south-west;
- the height of the containers on the laydown area have been limited to two containers high only at the laydown site;
- a 4m high noise attenuation bund at the northern boundary of the laydown platform is proposed and would provide some visual screening. It would be formed from topspoil arising from the site at 1:3 slopes and planted on the northern side facing Combwich village and Combwich Ponds. The side of the bund facing the laydown area would be grassed; and
- an acoustic fence is to be provided along the edge of the abnormal loads access route, which would include planting which is intended to screen the fence. The fence and planting would assist to screen activities on the wharf.

e) Air Quality

5.3.32 The impacts identified as of moderate significance in terms of air quality are related to fugitive dust and particulate matter generation causing potential nuisance to local receptors.

5.3.33 The construction and post-operational phases of the proposed development would result in **moderate adverse** impacts (prior to mitigation) on local residential receptors at 71 Estuary Park and 24 Riverside (within 50m of the proposed development site).

5.3.34 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site. These are presented within the **Air Quality Management Plan**. With controls in place no significant impacts are anticipated, although there may be some dust during the construction of the facilities.

f) Amenity and Recreation

5.3.35 The River Parrett Trail Public Right of Way (PRoW) (BW25/31) runs along the north-east boundary of the freight laydown facility and crosses the Combwich Wharf access road at the entrance to Combwich Wharf. In terms of other recreationa and amenity receptors, CMBSC is located at Combwich Wharf.

5.3.36 During the construction phase at Combwich Wharf and the freight laydown facility including works to construct the new flood defence bund, part of the construction for the Goods Wharf access road would take place where the River Parrett Trail PRoW BW25/31 crosses the existing Combwich Wharf access road. These works would temporarily obstruct and prevent access to and along the River Parrett Trail. The obstruction would be for a short duration but due to the sensitivity of the River Parrett Trail to obstruction (given the long distance from any other existing route) a high magnitude effect would arise. Consequently, given the high importance of this PRoW, a short-term and temporary **major adverse impact** is predicted. A diversion route would be provided for users of the River Parrett Trail to maintain access at all times during the construction phase including where required, around the area where the new flood defence bund would be constructed (and during the post-operational phase when the flood bund would be removed).

5.3.37 The construction works at the Wharf would result in an obstruction to the vehicular and pedestrian access to and from the CMBSC. This potential obstruction would extend for the 18 month duration of the construction phase and, without mitigation, would effectively prevent the Club from operating, unless mitigating measures are put in place. In addition, the presence of the Goods Wharf access road would result in the loss of an area of boat storage (around 300m^2) currently used by the Club.

5.3.38 Access to the CMBSC will not be obstructed at any time during the construction phase at Combwich Wharf. A temporary access road would be provided until the new Goods Wharf access road is constructed and access made available to the CMBSC. In addition, there will be no net loss of hardstanding area for the storage of boats as result of the proposed development. The extension to Combwich Wharf would result in the need to replace an existing pontoon currently located to the west of the Abnormal Load Quay. EDF Energy is committing to provide a replacement pontoon.

The timing for delivery of the replacement pontoon and its new location and design will be agreed at a later date in consultation with the CMBSC.

5.4 Summary of Impacts and Mitigation

5.4.1 This section of the report has focussed on identifying the negative impacts which the HPC Project is likely to have on Combwich. Because of its location at the mouth of the River Parrett, and its proximity to Hinkley Point plus the fact that Combwich is the location for one of the HPC Project off-site associated developments, Combwich is forecast to experience changes as a result of the project, particularly through the construction phase of the HPC development site. The principal effects are the landscape and visual impact of the new laydown area and the noise associated with unloading barges at the wharf – which may be necessary at anti-social hours in order to catch the tides. A series of measures are proposed to mitigate potential impacts, including landscape screening and a Noise Insulation Scheme, although impacts would remain. The laydown area would be removed and the land restored to countryside at the end of the HPC development site construction period. The existing wharf access road ensures that the village is not directly affected by the traffic generated by the use of the wharf or the laydown area.

5.4.2 Combwich is well placed for its residents to benefit from the extensive training and employment opportunities that would be available as a result of the HPC Project. Income for the village should also be generated by the demand from workers for accommodation during the construction period. Like other communities locally, Combwich is also eligible to apply for funds from the Community Impact Fund to support schemes that would enhance the quality of life in the village.

5.4.3 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Otterhampton has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

6. WILLITON

6.1 Introduction

6.1.1 As one of the closest settlements to the west of the HPC development site, and on the current transport route from Minehead and other settlements in West Somerset to Hinkley Point, Williton is anticipated to experience a number of effects from the construction, operational and post-operational phase of HPC.

6.2 Context

a) Local Area and Community Impacts

6.2.1 Williton is the main settlement in Williton CP, which also includes smaller villages including Doniford, to the north-east. Williton, the administrative centre for West Somerset Council, is at the junction of the A39, A358 and B3191 and roughly equidistant between Minehead, Taunton and Bridgwater, around 12 km from Hinkley Point. Williton has a population of around 2,750 people, with an older age profile than the national average. Existing levels of deprivation in Williton are relatively high (the east of Williton is within the 20% most deprived areas in England).

6.2.2 The elements of the HPC Project anticipated to result in impacts on the community in Williton are:

- the relative proximity of Williton to the HPC development site, and the location of Williton on transport links from the west to Hinkley Point; and
- the proposed park and ride site, to the west of Williton. The Williton facility principally proposes a park and ride facility for 160 parking spaces and a bus waiting area to facilitate the transfer of workforce to the HPC development site.

6.2.3 The transport strategy for the HPC Project has limited impacts on Williton through locating any associated development outside of the main settlement (the park and ride site is approximately 1.3km to the west of Williton). This was primarily in response to concerns raised through EDF Energy's consultation and the availability of a brownfield site outside of the village which met EDF Energy's requirements and provided a genuine alternative to providing a site in Williton itself. Nevertheless, because of Williton's location on the route to the HPC development site from the west, community impacts are most likely to arise in Williton as a result of the construction of the park and ride facility, and from the traffic generation linked to the construction phase of HPC. Impacts may also arise from workers who choose to live in Williton.

6.2.4 **Figure 27A.6** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

6.2.5 The nature of the HPC Project is such that associated developments are required to support the construction phase – in this case a park and ride facility is proposed to the west of Williton, south of Watchet, which would transport construction workers to the HPC development site. Without the park and ride site, construction workers from the west of Hinkley Point would be likely to drive to the site or along the A39 to Cannington. The park and ride site would cease to be needed once the power station is constructed and the site would revert to its previous condition and lawful use, which is as a lorry park**,** depot and storage area.

6.2.6 The proposal responds to a need to limit car movements through the rural area to the south-west of Hinkley and the site is considered to be well located to collect traffic from the rural area and allow its transfer to buses. Williton is the principal settlement in the area and proximity to it should assist in reducing the overall length of car journeys. The site at Williton was chosen because it has good access to the A39, its use would reduce the need for traffic to pass through Williton, it is previously-developed land and it is well screened by existing mature vegetation. Previously, EDF Energy proposed a site closer to Williton on greenfield land, which proved to be unpopular locally, as explained in the **Consultation Report.**

6.2.7 The **Alternative Sites Assessment** describes the site's credentials compared with other sites, whilst the **Consultation Report** describes how the site was selected.

6.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

6.3.1 The Williton ward cluster used as the basis for spatial analysis of population distribution in the socio-economic assessment (**Volume 2, Chapter 9** of the **Environmental Statement**) covers a wider area than Williton, also incorporating the settlement of Watchet and Old Cleeve, Crowcombe and Stogumber. This spatial area has a population of 11,000, while Williton has around 2,700 residents.

6.3.2 The number of non-home-based construction workers at peak forecast to be seeking accommodation in the area (150) is equivalent to around 20% of average annual new residents in the ward cluster, based on the number of new residents observed in the 2001 Census.

6.3.3 Although this is a relatively low proportion of the population, concerns about impacts of non-home-based construction workers on the supply of accommodation, public safety, community cohesion, the provision of services and the capacity of community facilities have been raised in consultation.

6.3.4 The ward cluster is anticipated to accommodate around 150 non-home-based residents, of which around 40 might be expected to stay in Williton village. Tourist accommodation is likely to account for around 60 of these construction workers, with around 40 in latent accommodation, around 25 in the private rented sectors and 25 in the owner-occupied sector. Using conservative estimates this is identified as being well within existing capacity (an estimated 120 tourist sector bedspaces are available even at August peak and 30 private rented sector bedspaces), taking into account turnover and vacancies.

6.3.5 EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The number of workers attracted to seek accommodation in Williton should be regulated by the available supply. The Accommodation Office for the HPC Project, however, would have the ability to direct new applicants away from Williton if there is evidence that the demand is excessive.

6.3.6 Workers resident in Williton may seek to place their children in the local primary school, although only a small proportion of workers are expected to bring children. There are two primary schools in the area: St Peter's Church of England First School, which has 33 surplus places, and Knights Templar Community School, to the north of Williton, with 40 surplus places. The local secondary school, Danesfield Community Middle School only takes pupils between the ages of 9 and 13 and has 56 surplus places. To a limited extent, demand from workers' children may help to support the schools.

6.3.7 Wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to leisure impacts, the overall effects on facilities in Williton are likely to be very small.

6.3.8 EDF Energy is also committed to invest in training and education facilities in order that local people can gain the skills and qualifications to work on the HPC Project both in the construction phase and in the completed development. The **Economic Strategy**, and the **Construction Workforce Development Strategy** which is appended to it set out a series of actions and investments which EDF Energy would undertake. These include investment in training facilities at Cannington and at Minehead, which should be accessible to Williton residents.

6.3.9 The project-wide mitigation package explained in Section 1 includes £250,000 for new or improved leisure facilities in West Somerset and Williton and WSC may decide that Williton is an appropriate location for that investment. Similarly, £2 million of the Community Impact Fund is ring-fenced for West Somerset (in addition to the money committed at Stogursey) and Williton would be well placed to bid for that money and for further awards from the wider Fund.

b) Transport

6.3.10 Given the location of Williton in relation to HPC and main transport links from Minehead and the rest of West Somerset, the general area could experience impacts related to traffic flows, severance and an increase in bus (and potentially limited HGV) frequency, and consequent community impacts related to air quality, noise and vibration and visual amenity.

6.3.11 The construction of the associated development site at Williton park and ride facility, together with the location of the HPC development nearby, would affect these impacts. The proposed park and ride facility at Williton would be located on an existing lorry park site on the B3190 to the west of Williton.

6.3.12 The main part of the transport mitigation comprises the transport strategy and the highway improvements. In addition, the effects of the construction of the HPC Project would be monitored throughout and if any unforeseen impacts are identified then EDF Energy would work with the authorities to mitigate their impact. Specifically in the context of Williton, the Washford Cross roundabout is proposed for improvement with a new, 4-arm roundabout at the existing junction of the B3190 and A39, approximately 1.5km to the west of Williton. These proposals would address an existing local safety problem with the junction and would comprise:

- realignment of existing carriageway and creation of new, four-arm roundabout;
- new full-depth carriageway constructed off the line of the existing road;

- existing carriageway to be broken out and area grassed or landscaped at eastern approach;
- existing carriageway at northern and southern approaches to be resurfaced;
- clearance of existing vegetation and removal of hedgerows;
- extension of field access to new boundary at northern approach;
- provision of new signage and road markings; and
- provision of new street lighting to meet standards to be agreed withSCC.

6.3.13 An assessment of the significance of the predicted increases in traffic as a result of the HPC Project is provided within **Volume 2, Chapter 10** of the **Environmental Statement** and the **Transport Assessment**, which is appended to the **Environmental Statement**.

6.3.14 As Williton is not located on the construction route for the HPC Project, the main increase would be as a result of an increase in the number of buses transporting workers to the HPC site. The scale of the increase in HGVs and buses through Williton, in 2013 and 2016, is predicted to increase from 308 HGVs/buses (2-way daily flows) in the Reference Case (existing flows, plus committed development plus background growth) scenario to 460 HGVs/buses with the HPC Project (including the mitigation package described above). This is equivalent to an increase of approximately 50% of existing HGV and bus flows through Williton. It is relevant however that the total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) would result in a significantly lower increase of 0.6% in all vehicles through Williton.

6.3.15 In 2021, the 2-way daily flows at the same assessment point are predicted to significantly decrease to 326 HGVs/buses with the HPC Project, an increase from 308 in the Reference Case. This is equivalent to an increase of approximately 5.8% of existing HGV and bus flows through Williton. The total daily traffic flows (2-way) as a result of the HPC Project (including mitigation) through Williton would be 0% in 2021.

6.3.16 The impact of these increases in traffic flows is assessed in terms of severance, pedestrian delay, pedestrian amenity, driver delay and accidents and safety. Severance is defined as perceived division that could occur within a community when it becomes separated by a major traffic artery and is therefore particularly relevant the consideration of impact on the community. The increases described above through Williton, in 2013 and 2016 is considered to be **moderate adverse** in terms of severance. In terms of the other assessment criteria, the increase in total traffic does not meet the relevant thresholds and therefore the impact is considered to be **negligible**. In 2021, all transport-related impacts through Williton would be reduced to **negligible**.

6.3.17 The character of the A39 through Williton would therefore experience some change as a result of HGVs and buses associated with the HPC Project, although it is relevant that there would only be a marginal increase in total traffic (less than 1%). This would however only be temporary, and would not persist following completion of the construction phase, when there would just be operational staff on the site. It is also relevant that the above figures are worst-case, particularly with regard to anticipated bus numbers. Timetables and routes have been developed for modelling purposes for the **Transport Assessment** to assess the worst-case impact that the provision of such services could have on the highway network. As the development progresses, EDF Energy would refine the bus services, routes and timetables to best serve the actual distribution of workers and this should enable the number of bus trips to be significantly reduced.

c) Noise and Vibration

6.3.18 The construction phase of HPC could result in impacts on the local community in terms of temporary traffic- and construction-related noise, and particular concerns have been raised in relation to residential amenity in terms of:

- daily road traffic noise impacts on the A39 in Williton at specific sensitive areas in the village;
- noise from construction works related to the Williton park and ride facility at residential properties including Smithyard Cottages; and
- disruption to amenity of users of PRoWs close to the associated development sites and resulting from traffic increases.

6.3.19 Without mitigation, significant adverse effects are projected to occur in 2016 (peak construction workforce) along the A39, at Williton and along the main route connecting the Williton park and ride site with the HPC development site (through Stringston and Stogursey). A medium magnitude of change is also predicted for some of the assessed night-time hours (before the start and after the completion of the principal shifts) on roads through Williton. This represents an impact of **moderate adverse** significance.

6.3.20 In terms of the impact of the construction phase of the park and ride facility, with all plant working at the closest approach, the impact of the construction works is predicted to be of **moderate adverse** significance at the closest residential properties (Smithyard Cottage). The highest predicted noise levels would occur during the earthworks and site preparation.

6.3.21 Specific mitigation that is required to reduce the predicted impact from site preparation and construction activities during works at the closest approach to the neighbouring residential property would include sites/compounds being provided with industry standard 2.4m hoardings within 100m of existing properties, or other barriers, where appropriate, and continuous noisy plant to be housed in acoustic enclosures.

d) Air Quality

6.3.22 The construction phase of HPC could result in impacts on the local community in terms of temporary reductions in air quality, and particular concerns have been raised in relation to locations in and around Williton relating to the construction and post-operational phases of the proposed development of the Williton park and ride facility, which would result in **moderate** impacts (prior to mitigation) on local human receptors at Smithyard Cottage.

6.3.23 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate matter emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**. As a result of the implementation of control methods, there are **no significant residual impacts**.

6.3.24 Ambient NO_2 pollutant concentrations at properties close to the main highway are currently relatively high in Williton owing to relatively high traffic flows, reduced speed (congestion) and narrowing of the A39.

6.3.25 The worst-case annual mean NO_2 vehicular contributions in the Williton model for the 2013, 2016 and 2021 'with development' scenarios are of no greater than small magnitude. Maximum worst-case vehicular contributions are observed at 'Williton County Stores' for the 2013, 2016 and 2021 'with development' scenarios for annual mean NO_2. The worst-case ambient concentration values for annual mean NO_2 for the 2013, 2016 and 2021 'with development' scenarios are all above the EU threshold limit. However, worst-case ambient concentration values for annual mean NO_2 for the 2013, 2016 and 2021 'without development' scenarios are all also above this threshold. This indicates that the annual mean NO_2 threshold would be exceeded without HPC Project traffic, and so would thus not be caused by either the construction or operation of the combined HPC Project.

6.3.26 The increase in traffic volume when comparing the 2013 'without development' and 'with development' scenarios represents only construction traffic for the Williton park and ride site, hence the extremely small NO_2 concentration increase associated with the HPC development in this assessment year. When comparing 2016 and 2021 'without development' and 'with development' scenarios, the increase in traffic volume represents only operational traffic associated with the Williton park and ride site, which is entirely composed of LDVs, hence the small NO_2 concentration increase. Therefore the impacts of 'with development' NO_2 ambient concentration values are predicted to be **minor adverse**. The worst-case potential impact on the human receptor locations is therefore **not significant**.

6.3.27 As such, for all assessed pollutants, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on human receptors for the 2013, 2016 and 2021 'with development' scenario is local, adverse, direct and likely. Potential impacts will be medium-term and temporary during the 2013 scenario, long-term and temporary during the 2016 scenario, and long-term during the 2021 scenario. The impact on the human receptor locations for all assessed pollutants is determined to be **not significant**.

6.3.28 Nonetheless, The **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards in order to mitigate for any potential adverse impacts relating to traffic flow increases in the area.

e) Landscape and Visual

6.3.29 The effects of the development on the landscape and visual amenity are related to:

- **Moderate adverse** impacts resulting from the construction phase of the Williton park and ride facility. Although the proposed development site itself would not be visible from the PRoW beside Cleeve Abbey, construction traffic would be visible moving across the landscape from Washford Cross along the B3190. During construction it is anticipated that there would be approximately 300 (two-way) HGV movements along the B3190.

- Moderate adverse impacts resulting from lighting within the proposed development on users of the PRoW beside Cleeve Abbey. Impacts or lighting during the operational phase are assessed as of **moderate adverse** significance at Viewpoint 4 (B3190 Footway) and Viewpoint 7 (National Trail near Orchard Wyndham).

6.3.30 Hours of working would be restricted to 08:00 to 18:00 Monday to Friday and 08:00 to 13:00 on Saturdays. Construction lighting would be shielded where possible and restricted to an hour either side of working hours to enable workers to arrive and leave safely, so potentially lit between 07:00 and 19:00.

6.3.31 The proposed development site is visible to drivers, pedestrians and users of the PRoW at Five Bells, however, in the Summer months, activities within the proposed development site would be strongly screened by existing, retained, vegetation along the bund to the north of the proposed HPC development site.

f) Recreation and Amenity

6.3.32 There are currently no PRoWs within or immediately adjacent to the Williton park and ride site. Consequently, there would be **no impact** on PRoW arising from obstruction during construction. However, impacts of **moderate adverse** significance may potentially arise as a result of visual and noise disturbance to users of PRoWs WL28/13, WL28/14, WL28/16, and WL28/18 during the construction phase of the Williton park and ride site, and during the operational phase at PRoW WL28/16 and WL28/18 due to the movement and activities of personnel and vehicles, and the presence of park and ride structures, which could result in an adverse impact on the amenity value of the PRoW in the study area.

6.4 Summary of Impacts and Mitigation

6.4.1 This section of the report has focussed on identifying the negative impacts which the HPC Project is likely to have on Williton. Because of its location on the road network, and being the only park and ride to the west of HPC, Williton is forecast to experience a certain degree of impacts, although these are limited due to the anticipated limited number of non-home-based workers in this area. However, Williton is likely to receive benefits from the wider scheme, including good access to the training and employment opportunities at HPC.

6.4.2 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Williton has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

6.4.3 In addition, Williton would be likely to benefit from the project-wide mitigation strategies explained in Section 1, including the Housing Fund, the investment in new or enhanced leisure facilities in West Somerset and a share of the Community Impact Fund.

7. PURITON

7.1 Introduction

7.1.1 Puriton CP is located to the north of Bridgwater, on the east of the River Parrett and includes the village of Puriton directly to the east of Junction 23 of the M5 motorway, and the smaller villages of Downend and Dunball to the west. Located around Junction 23 of the M5 motorway and the Dunball roundabout (A39 (Bristol Road)), this area is likely to experience impacts arising from the construction, operational phase and post-operational phase of the HPC Project.

7.2 Context

a) Local Area and Community Impacts

7.2.1 Puriton is a village to the north of Bridgwater, around 12 kmto the south-east of Hinkley Point. The population of the parish, which is mainly centred in Puriton but also in Downend and Dunball, is just over 2,000, with a slightly older than average age profile. There are around 900 homes in the area, although significant development is underway in the area to the south of Junction 23 of the M5 motorway, known as the North East Bridgwater development. The area does not suffer from high levels of deprivation and has low unemployment rates. A significant proportion of the jobs in the area are in distribution and manufacturing sectors.

7.2.2 Puriton lies directly to the east of Junction 23 of the M5 motorway, and Dunball roundabout on the A39. These junctions form part of one of the two main HGV routes from the motorway to HPC, which then run through Bridgwater and via Cannington to the HPC development site.

7.2.3 The elements of the HPC Project anticipated to result in impacts on the community in Puriton are:

- the nearby location of the village to strategic transport links from the M5 motorway to Hinkley Point; and
- the proposed Junction 23 site between the River Parrett and A38, which would include a park and ride facility, freight management facility, consolidation facility for postal/courier deliveries and an induction centre.

7.2.4 As such, community impacts are most likely to arise in Puriton as a result of the construction, operational and post-operational phases of facilities at Junction 23 to support the construction phase of HPC, and from subsequent traffic generation.

7.2.5 Indirectly, there could also be effects on local residents and users of community facilities, where amenity levels are affected by adverse impacts of the development on traffic, visual amenity, noise levels and recreation.

7.2.6 **Figure 27A.7** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

7.2.7 The nature of the HPC Project is such that associated developments are required to support the construction phase – in this case the park and ride facility, freight management facility, postal/courier consolidation facility and induction centre, to the west of Junction 23 of the M5 motorway.

7.2.8 The site is located directly to the west of the A38 Dunball roundabout and is currently used for agricultural purposes, comprising improved grassland fields and a large area of ruderal vegetation. It lies adjacent to commercial development to the north and to the south-east.

7.2.9 It is proposed to develop a hardstanding marked out for 1,300 vehicle parking spaces for use as a park and ride facility, 85 HGV spaces for a freight management facility, a consolidation facility for postal/courier deliveries and an induction centre on the site. A proportion of the vehicle parking spaces would be kept available for use in exceptional events such as unexpected peaks in demand or the temporary unavailability of other sites.

7.2.10 The site is considered suitable for this development as it is well located in proximity to Junction 23 of the M5 motorway and the A38 which leads to the HPC development site. It is ideally situated to intercept supply chain and construction worker traffic from the north before it enters Bridgwater. The site is large enough to accommodate the proposed development and is not in active use. It is reasonably enclosed by existing development and by vegetation and it can be developed without substantial intrusion into open countryside.

7.2.11 The proposals at Junction 23 would not be needed after the end of the HPC construction programme. Their future use would be controlled through the **Post-Operation Strategy** which would allow the local authority to determine the extent to which the built facilities whould be removed and the site restored.

7.2.12 The **Alternative Sites Assessment** describes the site's credentials compared with other sites, whilst the **Consultation Report** describes how the site was selected.

7.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

7.3.1 Puriton CP falls within the Burnham and Highbridge ward cluster used as the basis for spatial analysis of population distribution in the socio-economic assessment (**Volume 2, Chapter 9** of the **Environmental Statement**), although it is just on the edge of the Bridgwater ward cluster to the south. The Burnham and Highbridge cluster has a total population of over 41,000 people, although the Puriton area only accounts for around 2,000. As such, the Burnham and Highbridge area is anticipated to accommodate around 380 non-home-based construction workers at peak construction, but only around 10 are likely to be accommodated in Puriton.

7.3.2 This is a relatively low proportion of the local population and the scale of impact is unlikely to be such as to warrant concerns for the very local housing market or for wider issues such as community cohesion.

7.3.3 EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The number of workers attracted to seek accommodation in Puriton should be regulated by the available supply. The accommodation office for the HPC Project, however, would have the ability to direct new applicants away from Puriton if there is evidence that the demand is excessive.

7.3.4 Workers resident in Puriton may seek to place their children in the local primary school, although only a small proportion of workers are expected to bring children. Puriton Primary School is the only local school, and currently has 47 surplus places. The nearest secondary schools are in Bridgwater.

7.3.5 Wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to these impacts, the overall effects on facilities in Puriton are likely to be very small.

b) Transport

7.3.6 Given the location of Puriton in relation to HPC and main transport links from the M5 motorway, the general area could experience impacts related to traffic flows, severance and an increase in bus and HGV frequency.

7.3.7 As a result of the construction and operational phases of HPC, traffic flows on the M5 motorway Junction 23 southbound off-slip and northbound on slip roads are anticipated to increase from the present situation to 2016, as do flows on the A38 south of Dunball.

7.3.8 The main part of the transport mitigation comprises the transport strategy and the highway improvements. In addition, the effects of the construction of the HPC Project would be monitored throughout and if any unforeseen impacts are identified then EDF Energy would work with the authorities to mitigate their impact. Specifically in the context of Puriton, highway improvement proposals relate to minor physical works required to facilitate partial signalisation of Junction 23 of the M5 motorway. The proposals would be entirely within the existing carriageway and would comprise:

- minor carriageway widening;
- installation of traffic signals including signal control loops in approach carriageways;
- application of anti-skid coatings, road markings and additional signage; and
- provision of new street lighting to meet standards to be agreed with Somerset County Council (SCC).

7.3.9 Works also comprise minor improvements to the lane markings at Dunball roundabout which would improve links to Junction 23 of the M5 motorway, although these do not comprise physical works and therefore are not included as part of the Development Consent Order application. They have however been assumed to be part of the package of highway improvements for the purposes of the **Transport Assessment**.

c) Noise and Vibration

7.3.10 As a worst-case assessment, it is predicted that a maximum of 50 HGV movements per hour (including park and ride buses) would be generated on the A38 Bristol Road in 2016 between 05:00-06:00. Given the nature of the A39 in Puriton, there are very few residential properties that front the road, therefore the significance of increased traffic noise as a result of the operation of the Junction 23 site and construction phase of the HPC development site is **minor adverse**. Moreover, this assessment does not take account of potential screening by the proposed induction centre and postal/courier consolidation buildings on the site which are likely to significantly reduce potential impacts.

7.3.11 Additionally, potential noise and vibration impacts arising from the construction phase of the Junction 23 site on the closest residential property (The Woodlands) and PRoWs are considered to be of **minor adverse** significance given their distance from the site.

d) Air Quality

7.3.12 The construction phase of HPC could result in impacts on the local community in terms of temporary reductions in air quality, and particular concerns have been raised in relation to locations in and around Puriton relating to the construction and post-operational phases of the proposed development of the Junction 23 site. The closest residential properties to the proposed development site at are Junction 23 are '10 Bristol Road, located 144m from the site, and '2 Walpole Cottage' which is located 177m from the proposed site.

7.3.13 The significance of fugitive dust and particulate matter impacts at these receptors are predicted to be **negligible**, however best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate matter emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**.

e) Landscape and Visual

7.3.14 Potential impacts have been identified in relation to the construction phase of HPC in terms of community effects on visual amenity:

- Impacts associated with the construction phase when the movement of materials and the noise of construction of the Junction 23 site would disturb the peace of the Level and Moors landscape and Parrett riverscape character areas. This has been assessed as of **moderate to major adverse** significance;
- Also during the construction phase, views would be available of construction activities on the Junction 23 site including movement of materials, heavy machinery and HGVs. Impacts for the construction phase have been assessed as **moderate to major adverse** significance for certain viewpoints on the banks of the River Parrett;
- During operation disturbance would still be present with the daily movement of freight and other vehicles, along with users of the proposed induction centre. Impacts on the Levels and Moors and Parrett riverscape character areas have been assessed as of **minor to moderate adverse** significance; and

- During the operational phase the Junction 23 site lighting would be required 20 hours a day and from certain viewpoints on-site activities could be visible. Impacts have been assessed as of **moderate to major adverse** significance for certain viewpoints on the banks of the River Parrett and from Puriton Hill.

7.3.15 There are no specific measures being proposed as further mitigation for landscape and visual impacts during operation and post-operation. However, a number of design measures are included in the proposals which include:

- maintaining and reinforcing the landscape features of hedgerow, trees and ditches;
- Providing visual screen planting in the form of a 20m wide, 2m high bund and native screen planting of both young and semi mature plants (between 2m and 4m initial height) on the southern boundary to screen views from the River Parrett footpath; and
- providing additional planting along existing hedgerows to reinforce their value for screening.

7.3.16 Hours of construction working would be restricted to 07:00 to 19:00 Monday to Friday and 07:00 to 13:00 on Saturdays. Construction lighting would be shielded where possible and restricted to an hour either side of working hours to enable workers to arrive and leave safely, so potentially could be lit between the hours of 06:00 and 20:00 Monday to Friday and 06:00 to 14:00 on Saturdays. As described above, operational lighting would be required 24 hours a day at the Junction 23 site.

7.3.17 Close to the most southern boundary, where the Junction 23 site is closest to the River Parrett, a grassed bund with semi-mature trees planted along its crest and thick planting of smaller trees along the slopes, is proposed up to a maximum of 2m high to screen views from the river and from the PRoW which runs along both the eastern and western bank.

f) Amenity and Recreation

7.3.18 The main construction and operation area of the Junction 23 site does not contain any PRoW and, therefore, would not result in any obstruction. However, during the construction phase, the construction of flood defence works would result in a temporary (approximately eight weeks) obstruction to PRoW BW28/10, which runs along the east side of the River Parrett to the south and west of the development site (a strategic link between Bridgwater, Pawlett and Burnham and Highbridge). Consequently, prior to mitigation, a short-term reversible **moderate adverse impact** is predicted. However, a diversion route would be provided for users of PRoW BW28/10 to gain access around the construction area for the flood defence works. This diversion would add less than 50m to the existing route and would ensure that the right of passage is maintained, and that connectivity with the settlements of Bridgwater, Pawlett, Burnham and Highbridge would be maintained.

7.3.19 The assessment of visual and noise and vibration disturbance has identified **minor to moderate adverse** impacts on PRoW in the area, depending on the distance to the site. However, walkers using the PRoW usually would be transient and are, therefore, unlikely to be subject to more than short-term impacts. Hence, whilst the predicted noise and vibration and landscape and visual impacts might result in short-term disturbance as walkers pass near to the site, the impact on a person's enjoyment of the amenity is likely to be less significant than has been assessed.

7.3.20 Monitoring of access along the PRoW diversion would be undertaken on a weekly basis or in response to any concerns raised by users of the PRoW (or any member of the public) to the site office or site contact. The monitoring would ensure that access is not obstructed by growing vegetation or any other obstructions, and would lead to maintenance measures being carried out immediately (as necessary) to ensure that access is maintained. Furthermore, an appropriate mechanism for reporting, logging and investigating PRoW diversion complaints would also be employed and monitored during the construction programme, accompanied by an action plan to ensure that routes are not obstructed where issues arise.

7.4 Summary of Impacts and Mitigation

7.4.1 This section of the report has focussed on identifying the negative impacts which the HPC Project is likely to have on Puriton. Because of its location on the road network, and being a suitable location for a park and ride facility, freight management facility, consolidation facility for postal/courier deliveries and induction centre, the Puriton area is forecast to experience a certain degree of impacts. The principal impacts are transport related, with limited impact on residential amenity. A limited number of non-home-based workers are expected to seek accommodation in the area and this is not expected to generate adverse effects. As with other locations, Puriton is likely to benefit from access to the training and employment opportunities available at HPC.

7.4.2 A summary of the cumulative impacts of the elements of the HPC project on community receptors in Puriton has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

8. NORTH PETHERTON

8.1 Introduction

8.1.1 North Petherton, directly to the south of Bridgwater, is anticipated to experience impacts as a result of the HPC Project as a result of its location close to Bridgwater, the main urban centre in the area, and to Junction 24 of the M5 motorway. The A38 Taunton Road also runs directly through the parish and village, which is a strategic link between Taunton and Bridgwater running alongside (and linked to at Junction 24) the M5 motorway. A site close to Junction 24 of the M5 motorway would also be the location of an associated development for HPC, incorporating a park and ride facility, freight management facility, temporary consolidation facility for postal/courier deliveries and a temporary worker induction centre.

8.2 Context

Local Area and Community Impacts

8.2.1 North Petherton CP covers a wide area both sides of the M5 motorway south of Bridgwater, although the main population centre is in the North Petherton village on the A38 directly to the west of the M5 motorway. However, significant developments at Willstock Village and Stockmoor Village (also known as 'South Bridgwater'), adjacent to the Huntworth roundabout to the west of the M5 motorway between Bridgwater and North Petherton also fall within the area.

8.2.2 The population of North Petherton is approximately 6,000 people, and has experienced a fast increase since 2001, with an above average proportion of older people resident. In 2001, there were 2,200 dwellings in the area. Ward level data indicates that the dwelling stock increased by around 10% between 2001 and 2009. The area is not significantly deprived, with a strong employment base built on a significant proportion of warehouse and distribution jobs. Unemployment is generally low.

8.2.3 North Petherton has a number of outdoor grass pitches for cricket and rugby. There are facilities for gymnastics, cricket and athletics at North Petherton Community Junior School. There are additional accessible indoor leisure facilities in Bridgwater (see above and see **Volume 2, Chapter 9, Appendix 9E** of the **Environmental Statement**).

8.2.4 The elements of the HPC Project anticipated to result in impacts on the community in North Petherton are:

- the proximity of the HPC development site, and the location of North Petherton on strategic transport links from the M5 motorway to Hinkley Point; and
- the proposed associated development site, just to the north-west of Junction 24 of the M5 motorway, which would include a park and ride facility, freight management facility, temporary consolidation facility for postal/courier deliveries and temporary worker induction centre.

8.2.5 Community impacts are most likely to arise during the HPC Project in North Petherton as a result of the traffic generation linked to the construction phase of HPC and construction activities at Junction 24 affecting residential amenity.

8.2.6 Indirectly, there could also be adverse effects on local residents and users of community facilities, where amenity levels are affected by adverse impacts of the development on air quality, noise levels and recreation.

8.2.7 **Figure 27A.8** shows a plan of the parish, including elements of the HPC project in the local area.

b) Associated Developments

8.2.8 The nature of the HPC Project is such that associated developments are required to support the construction phase – in this case a park and ride facility, freight management facility, temporary consolidation facility for postal/courier deliveries and temporary worker induction centre. Junction 24 is a key location at which to intercept freight and worker journeys to Hinkley Point.

8.2.9 EDF Energy originally proposed the use of a greenfield site known as 'Bridgwater Gateway' for the location of the associated development at Junction 24. More recently, however, the former Somerfield storage/distribution facility came onto the market and, following consultation, EDF Energy has now adopted that site as its proposed location for the Junction 24 associated development facilities.

8.2.10 The Somerfield site was preferred by many because of its brownfield location. It also offers the important opportunity, given the existing infrastructure already available on the proposed development site, of being available and ready for use almost as soon as the DCO consent is granted, thereby providing a platform to manage and reduce transport impacts in the early years of the project.

8.2.11 The park and ride facility and freight management facility would be temporary facilities, but would be used for the entire construction phase of the HPC Project. After the construction of HPC, the site would be made available for alternative employment development.

8.2.12 The **Alternative Sites Assessment** describes the site's credentials compared with other sites, whilst the **Consultation Report** describes how the site was selected in preference to an alternative greenfield site, which had been proposed in earlier consultation.

8.3 Local Community Impacts and Mitigation

a) Population and Socio-economics

8.3.1 North Petherton falls within the wider Bridgwater ward cluster identified in **Volume 2**, **Chapter 9** of the **Environmental Statement**. However, on a ward level, the local area is anticipated to accommodate around 120 construction workers at peak construction in 2016 (around 9% of the non-home-based construction workers anticipated to live in the Bridgwater area).

8.3.2 Although this is a relatively low proportion of the population, concerns about impacts of non-home-based construction workers on public safety, community cohesion, the provision of services and the capacity of community facilities are relevant impacts that may be experienced by the local community.

8.3.3 In particular, impacts may arise relating to the capacity of tourist and private rented accommodation sectors, and in terms of the capacity of local schools, if the level of non-home-based construction workers exceeds the 'central scenario' outlined in **Volume 2**, **Chapter 9** of the **Environmental Statement**. The central scenario is based on a workforce profile at peak construction of 5,600 construction workers on the HPC development site and AD sites combined, of which 66% would be non-home-based i.e. requiring short-term accommodation. Modelling of anticipated distribution of construction workers estimates that there would be very low demand placed on the tourist and private rented sectors in this local area, with around 20 and 10 anticipated bedspaces required in each sector respectively, and around 75 in latent sectors (based on supply observed locally).

8.3.4 At a conservative estimate there is capacity to accommodate this demand in existing vacant bedspaces, although if non-home-based construction workers exceed the central scenario (as modelled and assessed in **Volume 2**, **Chapter 9** of the **Environmental Statement**), capacity issues could arise.

8.3.5 Potential impacts would be mitigated through workforce or accommodation management and contributions to policing and the public services described above. This includes a project-wide Housing Fund, and Community Fund, and an **Accommodation Strategy** that outlines measures that would be undertaken by EDF Energy to direct non-home-based construction workers to suitable accommodation to relieve capacity issues. In some cases such as leisure, local facilities would be enhanced and there would also be benefit from job and business opportunities, as identified through the **Economic Strategy**.

8.3.6 The demand for owner-occupied accommodation in the local area is also projected to be relatively low, and this would result in a low impact on demand for places in local schools. The **Heads of Terms for the Section 106 Agreement** propose advanced mitigation through early investment in primary school capacity in the wider Bridgwater area and a formula for payment towards increasing education capacity if monitoring identifies further impacts beyond existing capacity.

8.3.7 However, it is recognised that a concentration of worker population could have an impact on the quality of life of some residents. Therefore EDF Energy is proposing a Community Fund to spend on local initiatives which enhance the quality of life in local settlements. In addition, a **Worker Code of Conduct** would be implemented to pre-mitigate any adverse effects on public safety in the local area.

8.3.8 EDF Energy would also work with public service providers to identify potential impacts and ensure that measures are in place to mitigate them and, in some cases, provide local enhancements. These measures include contributions to emergency service and health providers based upon the numbers of workers assumed for their area. For education it includes contributions towards additional school places should these be required; and for leisure, EDF Energy also plans to make contributions to enhance the local recreational facilities.

b) Transport

8.3.9 Given the location of North Petherton in relation to HPC and main road transport links from the M5 motorway and population centres such as Bridgwater and Taunton, the general area has the potential to experience impacts related to traffic flows, severance, and an increase in HGV and bus frequency, and subsequent community impacts related to air quality, noise and vibration and visual amenity.

8.3.10 Impacts may also arise as a result of traffic flows related to the short-term construction activities at the Junction 24 site.

8.3.11 EDF Energy is promoting potential safety improvements at the A38/M5 motorway Junction 24 Huntworth Roundabout to improve the access to/egress from the Huntworth Business Park. This includes provision of a footway along the service road access to the Huntworth Business Park and an improved pedestrian crossing island across the service road access. These improvement works are anticipated to be in place by 2013.

8.3.12 In addition to proposed highway improvements EDF Energy proposes to contribute to potential safety enhancements and pedestrian and cycle improvements within Bridgwater that SCC are progressing as part of their ongoing programme of improvements.

8.3.13 In addition, the effects of the construction of the HPC Project would be monitored throughout and if any unforeseen impacts are identified then EDF Energy would work with the authorities to mitigate their impact.

c) Noise and Vibration

8.3.14 An assessment of construction activities at the Junction 24 site was undertaken with regard to potential noise and vibration impacts at the nearest noise-sensitive receptors (residential dwellings on the A38 and the new Stockmoor Village housing development). In addition, The Brainwave Centre to the north of the Junction 24 site was included as a receptor of high sensitivity.

8.3.15 The noise impacts of Junction 24 construction works are predicted to be of **minor adverse** significance in the short-term on all local residential properties assessed and The Brainwave Centre. With regard to vibration from construction activities on the Junction 24 site, due to the distance to the nearest sensitive residential property (over 70m from the site) the significance of the impact is predicted to be **minor adverse**.

8.3.16 During the operational phase, the principal noise sources associated with the operation of the proposed development include vehicle movements (HGVs, cars and buses) and plant operation on-site. Existing noise sources include the dominant road traffic noise from the nearby A38 and M5 motorway. The noise impacts of operation of the Junction 24 development is predicted to be of **minor adverse** significance. Due to the typically low vibration levels that are likely to be generated during the operation of the site (primarily by on-site vehicle movements), it is expected that operational activities would not result in perceptible vibration impacts on any of the identified receptors.

8.3.17 Best practice measures would be undertaken and are considered to form part of the proposed development. They would be based on the principles set out in the **Environmental Management and Monitoring Plan** (**EMMP)** with further information provided within the Subject Specific Management Plan: **Noise and Vibration (SSMP)**.

d) Air Quality

8.3.18 The construction phase of HPC could result in adverse impacts on the local community in terms of temporary reductions in air quality, and particular concerns have been raised in relation to sensitive receptors in and around North Petherton.

8.3.19 The key impacts of the construction of the Junction 24 site relate to fugitive dust and particulate matter generation causing potential nuisance to the closest human and residential receptors at '1 Dawes Farm Cottages', 'Moto Hospitality Services' and the 'Dwelling at Corner of Marsh Lane'. These receptors, located within 100m of the site are affected by predominantly easterly, north-easterly and southerly winds respectively, with meteorological conditions that may lead to fugitive dust and particulates at these locations occurring up to 4.7% of the time. The impact from dust at these receptors would be local, direct, **moderate adverse**, possible and temporary, lasting at most for the six month duration of the proposed construction activities at the Junction 24 site.

8.3.20 Best practice guidance control methods would be implemented to manage fugitive nuisance dust and particulate matter emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **Air Quality Management Plan**. As a result of the implementation of control methods, there are no significant residual impacts.

8.4 Summary of Impacts and Mitigation

8.4.1 This section of the report has focussed on identifying the negative impacts which the HPC Project is likely to have on North Petherton, and nearby receptors at Willstock and Stockmoor Village.

8.4.2 A summary of the cumulative impacts of the elements of the HPC project on community receptors in North Petherton has been undertaken as part of the Environmental Statement (**Chapters 5** and **6**, **Volume 11**).

8.4.3 Because of its location close to the M5 motorway and A38 on the strategic road network from Taunton to Hinkley Point via Bridgwater, the local area is forecast to experience impacts from the Project, principally related to construction traffic, and the construction and operation of the associated development at Junction 24 of the M5 motorway.

8.4.4 In terms of traffic flows, M5 motorway Junction 24 southbound off slip is the only link to have an impact of between 60% and 90% during the post-operational phase (2021), as the park and ride facility would remain operational at this point (in 2021). This is a moderate magnitude of impact but the slip road is a minor sensitivity receptor. Therefore the significance of the impact is **minor adverse**. During the early years, the Junction 24 site would be operational and highway improvements in place at the Huntworth roundabout, and no significant increase in flow is anticipated at this stage of peak construction in 2016.

8.4.5 Due to the Junction 24 site's current brownfield use, and history of operation as a freight handling site (and consequent short-term construction phase), the significance of impacts is lower than for other localities.

[This page is intentionally left blank]

9. DISTRIBUTION OF NON-HOME-BASED CONSTRUCTION WORKERS

9.1 Introduction

9.1.1 A model has been developed as part of this project to estimate the likely spatial distribution of non-home-based workers in areas within 60 minutes[2] of the HPC site, at peak construction in 2016.

9.1.2 The Gravity Model applies to a peak workforce of 5,600 construction employees of whom approximately 66% (3,696) would be non-home-based. As referred to above, it is anticipated that the purpose-built accommodation campuses would account for around 500 of these construction workers at the on-site accommodation campus, and around 1,000 in Bridgwater, although actual numbers in campuses at any one time will be slightly lower due to turnover of workers. The remaining non-home-based construction workers would be split between private rented, tourist, owner occupied and latent accommodation.

9.1.3 This section outlines the community impacts for those areas (ward clusters) slightly further afield where the assessments suggest that there may be a concentration of more than 100 non-home based workers drawn to the area to work on the HPC Project during its construction, and therefore where there may be community impacts in terms of capacity of public services and community facilities.

9.2 Minehead

9.2.1 The Minehead area includes the coastal town of Minehead and smaller surrounding villages including Dunster, Carhampton and Withycombe, as well as Porlock further to the west. The total population is around 17,000 people, of whom around 10,000 live in Minehead town.

9.2.2 As a result of the peak construction phase at HPC, it is anticipated that around 120 non-home-based workers would live in this area. This is equivalent to around 8% of average annual new residents, and a very small proportion of the current existing population.

9.2.3 Given the relatively high proportion of tourist accommodation in the area, around 50 of these construction workers are likely to take up accommodation in the tourist sector, with around 30 in private rented sector and 15 in owner occupied homes. The remaining 25 would be anticipated to take up spaces in latent accommodation (where local residents have expressed an interest in renting spaces, often spare rooms in houses).

9.2.4 Based on calculated supply, there are currently around 230 vacant bedspaces in tourist accommodation at the August peak, and around 60 bedspaces in the private rented sector. Using conservative estimates, therefore, the take up by Hinkley

[2] This includes drive time to the closest park & ride, transfer, and bus journey to site.

workers is identified as being within existing capacity, taking into account turnover and vacancies.

9.2.5 Nonetheless, EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The accommodation office for the HPC Project would have the ability to direct new applicants away from Minehead if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit Minehead and its residents in the event that hardship is being caused.

9.2.6 Of the non-home-based construction workers anticipated a peak construction around 15 would be likely to move their families into the area, resulting in an estimated six primary and four secondary school aged children moving to the area. Primary schools in the Minehead area currently operate at only 64% capacity, with around 370 surplus places, anticipated to be more than enough capacity to support any construction workers' children. There is also significant capacity at secondary level (15% surplus capacity, or around 290 surplus places).

9.2.7 EDF Energy is committed to investment in training and education facilities in order that local people can gain the skills and qualifications to work on the HPC Project. As such, Minehead would benefit from investment at West Somerset Community College including the Hinkley Ready skills project and an Enterprise Project in order to enable local people to gain the necessary skills to provide services to the construction and operational workforce.

9.2.8 Wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to leisure impacts, the overall effects on facilities in Minehead are likely to be very small.

9.3 Weston-super-Mare

9.3.1 The Weston-super-Mare area includes the large coastal town of Weston-super-Mare and Clevedon to the north, as well as local villages including Hutton, Locking, Winscombe and Churchill, in the unitary district of North Somerset. The total population of the area is around 124,000 people, of whom around 72,000 live in the wider Weston-super-Mare area.

9.3.2 As a result of the peak construction phase at HPC, it is anticipated that around 450 non-home-based workers would live in this area. This is equivalent to around 8% of average annual new residents, and a very small proportion of the current existing population.

9.3.3 Given the relatively high proportion of tourist and private rented accommodation in the area, around 70 of these construction workers are likely to take up accommodation in the tourist sector, with around 290 in the private rented sector and 100 in owner occupied homes. Due to the low level of interest expressed locally in renting spare rooms, latent accommodation is likely to constitute a negligible portion of supply.

9.3.4 Based on calculated supply, there are currently around 360 vacant bedspaces in tourist accommodation at the August peak, and around 780 bedspaces in the private rented sector. Using conservative estimates the likely Hinkley take up is identified as being well within existing capacity, taking into account turnover and vacancies.

9.3.5 Nonetheless, EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The accommodation office for the HPC Project would have the ability to direct new applicants away from Weston-super-Mare if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit Weston-super-Mare and its residents in the event that hardship is being caused.

9.3.6 Of the non-home-based construction workers anticipated a peak construction around 100 would be likely to move their families into the area, resulting in an estimated 35 primary and 25 secondary school aged children moving to the area. Primary Schools in the area currently operate at 85% capacity, with around 1,400 surplus places, anticipated to be more than enough capacity to support construction workers' children. There is also significant capacity at secondary level (13% surplus capacity, or around 800 surplus places).

9.4 Burnham and Highbridge

9.4.1 The Burnham and Highbridge area includes the area either side of the M5 motorway north of Bridgwater from Junction 23 to the River Axe, including the coastal town of Burnham-on-Sea and Highbridge, and smaller surrounding villages including Woolavington and Puriton to the south, and Wedmore to the east. The total population is around 41,000 people, of whom around 20,000 live in the Burnham-on-sea and Highbridge urban area.

9.4.2 As a result of the peak construction phase at HPC, it is anticipated that around 380 non-home-based workers would live in this area. This is equivalent to around 14% of average annual new residents, and a very small proportion of the current existing population.

9.4.3 Given the relatively high proportion of tourist accommodation in the area, around 200 of these construction workers are likely to take up accommodation in the tourist sector, with around 65 in private rented sector and 75 in owner occupied homes. The remaining 40 would be anticipated to take up spaces in latent accommodation (where local residents have expressed an interest in renting spaces, often spare rooms in houses).

9.4.4 Based on calculated supply, there are currently around 590 vacant bedspaces in tourist accommodation at the August peak, and around 90 bedspaces in the private rented sector. Using conservative estimates this is identified as being within existing capacity, taking into account turnover and vacancies.

9.4.5 Nonetheless, EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The accommodation office for the HPC Project would have the ability to direct new applicants away from the Burnham and Highbridge area if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit the Burnham and Highbridge area and its residents in the event that hardship is being caused.

9.4.6 Of the non-home-based construction workers anticipated a peak construction around 75 would be likely to move their families into the area, resulting in an estimated 25 primary and 20 secondary school aged children moving to the area. Primary Schools in the area currently operate with around 6% capacity, with around 175 surplus places. This is anticipated to be more than enough capacity to support construction workers' children.

9.4.7 In order to head off any potential shortfall in capacity, EDF Energy's proposals described in Section 1 include a formula for payment towards increasing education capacity further if monitoring identifies further impacts beyond the enhanced capacity. Such improvements would ultimately need to be agreed between the County Council and individual schools.

9.4.8 Wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to leisure impacts, the overall effects on facilities in Minehead are likely to be very small.

9.5 Taunton

9.5.1 The Taunton area includes the built-up area of Taunton, along with nearby Staplegrove, North Fitzwarren and Trull. It also contains villages to the north and west including Kingston St Mary and Bishops Lydeard. The total population is around 74,000 people, of whom around 61,000 live in the Taunton urban area. Taunton is the county town (and largest town) of Somerset.

9.5.2 As a result of the peak construction phase at HPC, it is anticipated that around 360 non-home-based workers would live in this area. This is equivalent to around 7% of average annual new residents, and a very small proportion of the current existing population.

9.5.3 Given the relatively high proportion of private rented accommodation in the area, around 135 of these construction workers are likely to take up accommodation in the private rented sector, with around 85 in the owner-occupied sector and 30 in the tourist sector. Given the high level of interest registered by local residents in providing accommodation, the remaining 120 would be anticipated to take up spaces in latent accommodation (where local residents have expressed an interest in renting spaces, often spare rooms in houses).

9.5.4 Based on calculated supply, there are currently around 170 vacant bedspaces in tourist accommodation at the August peak, and around 240 bedspaces in the private rented sector. Using conservative estimates this is identified as being within existing capacity, taking into account turnover and vacancies.

9.5.5 Nonetheless, EDF Energy would seek to avoid any workforce concentrations in excess of local capacity through workforce or accommodation management measures and contributions outlined in Section 1 of this report. The accommodation office for the HPC Project would have the ability to direct new applicants away from the Taunton area if there is evidence that the demand is excessive. Similarly, the wider Housing Fund would be available to benefit the Taunton area and its residents in the event that hardship is being caused.

9.5.6 Of the non-home-based construction workers anticipated a peak construction around 85 would be likely to move their families into the area, resulting in an estimated 30 primary and 20 secondary school aged children moving to the area. Primary Schools in the area currently operate with around 7% capacity, however this is equivalent to around 370 surplus places. This is anticipated to be more than enough capacity to support construction workers' children. Secondary Schools are currently operating close to capacity, with around 30 surplus places.

9.5.7 In order to head off any potential shortfall in capacity, EDF Energy's proposals described in Section 1 include a formula for payment towards increasing education capacity further if monitoring identifies further impacts beyond the enhanced capacity. Such improvements would ultimately need to be agreed between the County Council and individual schools.

9.5.8 Wider mitigation strategies outlined in Section 1 address other impacts on health and public services. In relation to leisure impacts, the overall effects on facilities in Taunton are likely to be very small.

9.5.9 As a result of the above analysis, and with the proposed project-wide mitigation strategies in place, adverse impacts are not anticipated to arise in the areas beyond the local settlements.

APPENDIX A: CONTEXT OF HPC PROJECT (SECTION 3 OF THE PLANNING STATEMENT)

[This page is intentionally left blank]

CONTENTS

TABLES

[This page is intentionally left blank]

A. CONTEXT OF HPC PROJECT (SECTION 3 OF THE PLANNING STATEMENT)

A.1 Introduction

The principal events in the main site's planning history are as follows:

- The 1988-1989 Hinkley Point C planning inquiry;
- Site nomination in National Policy Statement EN-6; and
- The site preparation planning application submitted on behalf of EDF Energy to West Somerset Council in 2010.

A.1.1 There has been at least one nuclear power station at Hinkley Point since 1965 when Hinkley Point A was commissioned. Whilst the A station is no longer operating and is the subject of a programme of decommissioning, Hinkley Point B was commissioned in 1976 and will continue to operate at least until 2016. The suitability of the general location for the development of a C station has been established in principle through the extensive studies which support up to date policy set out in the National Policy Statement on nuclear power (EN-6 *National Policy Statement for Nuclear Power Generation, June 2011)* (NPS EN-6) and through the site's own planning history.

A.2 The 1988-1989 Hinkley Point C Planning Inquiry

A.2.2 A previous proposal for a nuclear power station in approximately the same location as the current proposal was considered at a planning inquiry spanning 1988-89. Permission was granted but never implemented. The Inspector's report and Secretary of State's decision letters provide some helpful context for the consideration of the current HPC project, although a number of matters have moved on significantly since that time.

A.2.3 In 1987 the Central Electricity Generating Board (CEGB) applied to the Secretary of State for Energy for deemed planning permission for an additional generating station at Hinkley, to be known as Hinkley Point C. A separate application was made in September 1987 to realign overhead transmission lines at Hinkley and in June 1988 the CEGB applied for the confirmation of a compulsory purchase order in respect of land required in connection with the development.

A.2.4 Three public inquiries were held jointly between October 1988 and December 1989. The Inspector's report into the principal application and the CPO was published on 4th June 1990 recommending approval of the deemed planning application. The Inspector recommended that the "*benefits substantially outweigh the disadvantages*". In letters dated 6th September 1990, the

Secretary of State for Energy accepted the Inspector's recommendations, granted deemed planning permission for the power station but refused to confirm the CPO because of uncertainty about the implementation of the development.

A.2.5 A substantial amount of the inquiry was taken up with issues relating to energy policy, need etc as the project did not benefit from a clear statement of national policy, as is currently provided by the designated National Policy Statements. There were a number of site specific considerations, however, which may contain some lessons for the current project. Many of the issues relevant at that time are also relevant today, as is amplified in the following paragraphs.

a) Ecology

A.2.6 The Inspector recognised that the construction and operation of a PWR at Hinkley Point was certain to have some adverse effects on the ecology of the site and the surrounding area: for example, the effect on grass land on the cliff top, the disturbance of nightingale habitats on the construction site and the possible need for dredging in the River Parrett. However, the Inspector also concluded that there was "*no obvious or special ecological importance in the area"* which would be immediately affected by the proposed development (Inspector's report paragraph 58.42). In particular:-

- the bird breeding community of the area appeared to be typical of lowland England;
- there was no evidence that the process would have lasting adverse effects on fisheries or fish life or other marine life;
- there was no hard evidence that the A and B stations have had a major adverse effect;
- the presence of a regionally uncommon bee orchid on ground used during the construction of Hinkley A demonstrated that the species could survive in the area restored after construction;
- nightingales have survived the disturbance of construction of the A and B stations and now nest close to the main gate;
- the Inspector did not accept that up to 80 vessels coming to Combwich Wharf over 2 years would have great effect on the ecology of the river or the estuary; and
- the Nature Conservancy Council (now Natural England) raised no objection to the development or its effect on the SSSI and were satisfied with the proposed Ramsar land exchange, which would be a net benefit to the Ramsar (58.46).

A.2.7 The exchange land was known as the Island Saltings on the east of the River Parrett, which was offered in exchange for that part of the foreshore affected at Hinkley Point (58.8). The Inspector concluded that the adverse ecological effects would not be of a major or serious nature.

b) Visual Impact

A.2.8 The Inspector identified that Hinkley Point lies close to the transition zone between the upland areas to the west and the low lying area to the east (55.5). The Inspector concluded that claims for the attractiveness of the area around Hinkley Point were justified. Whilst it was not a grand landscape, it had a restrained beauty of its own which grows on the visitor. One of its main characteristics was its variety, ie the variety of different landscapes which appear within a small area (55.41).

A.2.9 The Inspector considered that the present A and B stations do have a substantial visual impact on the area – an impact which is greatest on the coast to the west and on the low lying area to the east. He considered that there was a noticeable but lesser impact on views from the Quantocks because of the "largeness" of the views available (55.43). When viewed from the Quantocks and from the moors, Hinkley C would have doubled the apparent length of the existing power station site. From the coast, however, the C station would either help to hide or would be partly hidden by the A and B stations. In the Inspector's opinion, the effect of a C station would be less than the gross and unacceptable additional visual intrusion which some people alleged particularly because:-

- it is a very different thing to propose the extension of an existing site than to propose its initial establishment. If new nuclear power stations are to be built on the coast they should, where possible, be built alongside existing stations – this is a powerful argument when it comes to questions of visual impact;
- the Inspector did not find the appearance of a PWR as unattractive as many industrial installations. There would be none of the smoke, grime or noise associated with heavy industry and the cold, scientific, some what futuristic aura of a PWR would be much less out of place in a coastal setting than many other forms of development;
- the visual improvement in the appearance of a C station over the existing stations would be more than the slight improvement alleged by some witnesses;
- some of the concern expressed by objectors appeared to relate to their deep dislike of anything nuclear, rather than visual impact; and
- *"the views from the Quantocks are of great importance, but here I believe the additional length of the Hinkley Point site would be muted in its effect by the very extent of the panoramic views available." (55.45)*

A.2.10 The Inspector found that the greatest impact of a C station would be on views from the coast to the west and from the low lying moors to the east and south-east. It was here that landscaping proposals would be of most importance and could do much to obscure the clutter of lower buildings on the site. The Inspector considered that the adverse effects of the existing stations are least damaging when seen from the west because of the undulating landscape which reduces their visual clutter (56.76). Nevertheless, the Inspector identified that all that can reasonably and properly be done to restrict adverse effects should be done.

A.2.11 The Inspector did conclude that the C station would have an adverse visual effect on a local area which has a substantial and varied visual beauty (55.46). Nevertheless, he did not regard the visual impact "*as being so gross and serious*" that the project became unacceptable in principle, although landscaping would be important.

A.2.12 However, the Inspector was not content with the CEGB's proposed landscaping approach. In particular, the Inspector expressed concern about the loss of nearly 0.5km of cliff and nearly 3 ha of foreshore which CEGB had failed to properly justify. The evidence showed that a shorter sea wall could protect the station just as effectively (56.72).

A.2.13 The Inspector considered that the aim of landscaping was to mask and improve the visual impact of the proposed development, including its construction (56.94) in particular. There was genuine merit in hiding the clutter at the lower levels of the development and this was more important than being able to visually establish the base of the dome.

A.2.14 The Inspector concluded, however, that the CEGB proposals could be materially improved in 7 ways including reduced impact on the sea wall, planting of the northern ridge, raising the crest of the southern ridge, improving planting on the western screen ridge, providing a temporary mound to the west of the contractors' area and increased efforts in relation to off-site landscaping (56.100). Accordingly, the Inspector concluded that a condition should be proposed requiring the submission of a revised landscaping proposal before the commencement of the development.

c) Accommodation and Housing Issues

A.2.15 The evidence indicated a construction workers' peak of 3,500 in year 4 and an estimate that the number of in-migrants seeking accommodation in the area would be around 1,700 (61.4). The Inspector concluded that the districts of Sedgemoor, West Somerset and Taunton Deane were a reasonable area for assessment when considering accommodation impact. An on-site hostel containing 400 spaces, which could be increased to 700 spaces was proposed. By way of background it was explained that:-

- in March 1989 WSC had refused planning consent for a mobile home site near Watchet;

- during the construction of the A and B stations, caravan sites were established near Stogursey but were not properly managed and caused considerable disturbance; and
- it was agreed that a site to accommodate 80 caravans should be provided by CEGB, although a specific site was not identified – it would need to be established in good time.

A.2.16 There was dispute over the best location for the hostel. WSC considered that, if there were to be a hostel, it should be on site. Local residents, however, favoured a location well away from the site because of fears of disturbance from workers.

A.2.17 The Inspector did not find the issue easy to decide. He had no doubt that a hostel was desirable and there were obvious common sense advantages in it being located adjacent to the construction site. It would be considerably more convenient for the occupants and the site operator and would reduce traffic on roads. Local concerns could not be lightly dismissed but, to some extent, this concern was a legacy of the previous experience and a balanced judgement had to be struck. The Inspector concluded that the obvious advantages of an on-site hostel, combined with the fact that some of the causes of the disturbance in earlier years could be removed through better management, tipped the balance in favour of the hostel being on the site.

A.2.18 Concern was also expressed about pressure on the local housing market and the increased burden that would fall on WSC as the local housing authority. WSC sought a commitment from CEGB that they would be reimbursed any additional expenditure on housing services but the Inspector did not consider this to be reasonable (61.41). The Inspector did not think that the additional burden would be significant and reminded the authority of their statutory duties.

d) Transport

A.2.19 The construction of Hinkley Point C was anticipated to involve the transport to the site of about 1.5 million tonnes of material and plant, with a peak labour force estimated at 3,500 workers, on top of about 330 operational staff who would also be present in the peak construction year. Long term operational staff would number approximately 470. Use was to be made of Combwich Wharf for abnormal loads but the Inspector agreed that access by rail was not feasible and that access by sea could not be achieved because the construction of a new harbour or dock would have adverse environmental effects. All traffic, therefore was expected to drive direct to the site, which offered 1,400 on-site parking spaces. HGVs and lighter commercial vehicles were likely to generate over 1,000 movements per day in the peak construction year.

A.2.20 CEGB's case was that all traffic generated, with the exception of a few abnormal loads which would use the wharf at Combwich, would be carried entirely by road and that the existing road network would be adequate to carry the additional traffic. The coalition of local authorities (COLA) disagreed and their case was that the extent of additional traffic warranted the construction of bypasses for Bridgwater and Cannington.

A.2.21 An agreement was reached between CEGB and COLA in relation to the bypass. In July 1988, CEGB offered to contribute £10 million towards the construction of the bypasses and other minor road works, conditional on the County Council withdrawing objections to the construction of Hinkley Point C on transport grounds. As a result, no detailed transport evidence was heard at the inquiry and, in the light of the commitment given by CEGB towards the bypass, the Inspector did not think it reasonable to impose a condition requested by SDC that the bypass should be in place before construction could commence (62.13).

A.2.22 The proposed bypass would run from the A38 near Dunball, crossing the River Parrett by an opening bridge and proceed for 3.37 miles to join the A39 to the south-east of Cannington. It would continue around the south of Cannington to rejoin the A39 near Brymore School and connect from there around the north west of Cannington to join the C182 at Rodway.

A.2.23 CEGB had obtained planning permission to construct a new road to the south of Combwich to bypass the village when using the wharf (62.54). This road has since been constructed, as has the southern section of the Cannington Bypass.

A.2.24 Because the Inspector had no detailed transportation evidence, he concluded that, in the event that the Secretary of State failed to confirm the necessary orders for the Bridgwater and Cannington Bypasses, the inquiry would need to be re-opened (62.68).

A.2.25 The Secretary of State for Transport subsequently confirmed the Side Road Orders and Bridge scheme necessary for the construction of the proposed Cannington and Bridgwater bypasses.

e) Overall Conclusions

A.2.26 The Inspector's overall conclusions contain substantial discussion about need and policy. In these respects the Inspector concluded that there was a likely capacity need, that there were benefits in adding a degree of diversity to sources of generation supply and to provide security against volatile movement in the price of fossil fuels, as well as security against long term uncertainties. The Inspector also identified that the grant of consent would mean that

> *"a plant could be constructed which would have major environmental benefits compared to some other forms of generating plant….It is too early to reach a general conclusion on the scale or the imminence of the threat which may be posed by global warming, but there appears*

> *to be an increasing likelihood that international action, perhaps on a drastic scale, will be needed to meet the threat. It seems to me that there is a major benefit in granting consent for a large electricity generating plant which will in its normal operation create no pollution of the types just mentioned or indeed no significant atmospheric or environmental pollution." (para 15).*

A.2.27 Against this finding of significant benefit, the Inspector identified disadvantages, including the costly generation of electricity and the creation of any risk to safety or health. In relation to environmental effects, the Inspector concluded the following:-

> *"22. Thirdly, the effect of the proposed plant in the local area would in my opinion be generally be disadvantageous. The main adverse impact would be visual since the plant would be set in an attractive coastal and rural area. There would be local benefits such as the provision of employment and a contribution to road improvements and the development in visual terms must be seen in the physical context of the existing site with its two power stations, but the overall effect would be clearly disadvantageous. I can state this element of disadvantage briefly but it is one in my judgment that would figure substantially in any overall weighing.....the adverse local effects thus weigh heavily in my mind when considering the disadvantages side of the balance."*

A.2.28 The Inspector identified adverse effects of the development on the locality as disadvantages to which he would attach particular weight (para 27). However, when considering the benefits of granting consent, the Inspector was "*clear that the benefits substantially outweigh the disadvantages".*

A.2.29 The Secretary of State's decision letter identified as a principal issue "*whether there are any local or environmental considerations which prevent the grant of this consent*". Under that heading, the Secretary of State:-

- accepted the Inspector's conclusion that, although the visual and other disadvantages outweigh the local benefits, they were not such as to prevent the grant of consent, although they do need to be considered in the final balance of benefits and disadvantages;
- accepted the Inspector's outline conclusions for the shortening and realigning of the sea wall which would have preserved more of the existing cliff line and allow for further improvements to CEGB's landscaping proposal;
- agreed that the land sought to be acquired by compulsory purchase would not be excessive except that part which would not be needed if the sea wall were shortened;
- accepted that a temporary hostel should be provided on site for construction workers; and

- accepted that the construction of a rail link would not be practical.

A.2.30 Accordingly, the Secretary of State agreed that the local impact was on balance negative but had to be considered in the context of an existing site with two nuclear stations which are unlikely to be dismantled for many years. The Secretary of State concluded that strong importance should be attached to greater diversity of fuel supply and in particular – for global environmental reasons – greater diversification away from fossil fuels.

A.2.31 Accordingly, on 6th September 1990, the Secretary of State granted consent for HPC and its temporary workers hostel.

A.2.32 In relation to the compulsory purchase, however, the Secretary of State noted the uncertainty of Hinkley Point C proceeding having regard to viability and other issues. In the light of that uncertainty, the Secretary of State decided not to confirm the CPO (page 15).

A.2.33 There are, of course, many differences between the nature of the previous Hinkley Point C proposals and the current project and also between the policy and other circumstances which prevail then and now. However, the following conclusions remain relevant to the current proposals:-

- in principle, land which forms part of the main development site was found suitable for the development of a nuclear power station;
- if new nuclear power stations are to be constructed, it makes sense for them to be located in remote coastal locations but, particularly, for them to be located adjacent to existing nuclear power stations rather than generating fresh impacts;
- the development of Hinkley Point C provides the opportunity to improve the screening and visual appearance of the existing power stations. Landscaping is important, however, and a careful and comprehensive approach is required which respects the natural features of the site and screens, particularly, the 'clutter' of lower level development and activity;
- views of the development from the Quantocks are important but are not, in principle, unacceptable because of the scale of panorama available from the Quantocks and the presence of the existing power stations; and
- there is benefit in providing accommodation for construction workers on site, as long as it is properly managed.

A.3 Site Nomination and Selection

a) Policy Background

A.3.34 In the period 2005-2008, the Government undertook a comprehensive review of national energy policy, within the context of its policies for climate change. As part of that review, a series of consultation documents and subsequent policy statements were published relating to the UK's energy needs and the strategy for meeting those needs. These included the following:

- '*The Energy Challenge'* Energy Review Report, July 2006 (Ref.4.28);
- '*Meeting the Energy Challenge'*: A White Paper on Energy, May 2007 (Ref.4.29);
- Consultation paper 'The Future of Nuclear Power: The Role of Nuclear Power in a Low Carbon Economy', May 2007 (Ref.4.30);
- '*Meeting the Energy Challenge'*: A White Paper on Nuclear Power, January 2008 (Ref. 4.31);

A.3.35 The Energy White Paper, May 2007 and the Nuclear Power White Paper, January 2008 established that new nuclear power stations should have a role to play in this country's future energy mix, alongside other low-carbon sources. In particular, the White Paper on Nuclear Power included a foreword from the then Prime Minister which advised:

> *"More than ever before, nuclear power has a key role to play as part of the UK's energy mix. I am confident that nuclear power can and will make a real contribution to meeting our commitments to damaging climate change."*

A.3.36 And the separate foreword from the then Energy Minister advised:

> *"Against the challenges of climate change and security of supply, I believe that the evidence in support of nuclear power is compelling and that we should positively embrace the opportunity of delivering this important part of our energy policy."*

A.3.37 The White Paper itself established what the Government will do to implement its policy, ie:-

> *"3.1 The Government has reached the conclusion that new nuclear power stations can help the UK to meet its objectives on climate change and energy security. We conclude, therefore, that it would be in the public interest to allow energy companies the option to invest in new nuclear power stations. The Government will take a number of facilitative actions to reduce regulatory and planning risks associated with investing in new nuclear power stations and to ensure that owners and operators of new nuclear power stations set aside funds over the operating life of the power stations to cover the full costs of decommissioning and their full share of long-term waste management and disposal costs. These facilitative steps…..will reduce uncertainties in the pre-construction period through improvements in the regulatory and planning processes."*

A.3.38 In relation to planning, the White Paper referred directly to reforms promoted in the then Planning Bill for a fundamental reform of the planning system for nationally significant major infrastructure projects. These included proposals to establish the Infrastructure Planning Commission (the IPC) to determine applications for major infrastructure proposals within the context of new National Policy Statements (NPS). The Nuclear White Paper then explained:-

> *"3.4 The Government's intention is that the inquiry phase of any application for a new nuclear power station should examine the proposals in the context of the national strategic or regulatory material considerations, which will already have been established through our facilitative action. It should examine the local benefits of the development and how local impacts of the construction and operation of the plant can be minimised. The purpose of our facilitative action is, therefore, to handle these national strategic and regulatory material considerations and enable the consideration of the proposal to progress effectively and efficiently."*

A.3.39 For nuclear power stations at least, this new approach to planning for infrastructure was to involve the identification of specific sites.

A.3.40 The White Paper, therefore, put in train a series of actions for this purpose. Those steps taken in accordance with the White Paper have included the following:-

- consultation on draft criteria for a Strategic Siting Assessment (SSA) of potential sites for new nuclear power stations;
- undertaking a Strategic Environmental Assessment (SEA) as part of the SSA process and a Habitat Regulations Screening Report;
- inviting nominations for potential sites to be considered in the SSA and consulting on a draft list of nominated sites, followed by the assessment of appropriate nominated sites against the SSA criteria and a further public consultation exercise inviting views on those nominated sites judged by the Government to meet the criteria;
- undertaking an Alternative Sites Study (a Government – commissioned strategic level screening exercise to identify whether there are any other sites in England and Wales that are potentially suitable for the deployment of new nuclear power stations before the end of 2025 and which had not been nominated);
- preparing an Appraisal of Sustainability and a Habitat Regulation Assessment conducted at a strategic level for each site and for an emerging National Policy Statement on nuclear power;
- consultation on draft National Policy Statements (NPS);
- taking advice from specialists such as the Nuclear Regulators, including the assessment of sites against specific criteria;

- parliamentary scrutiny of the NPS; and
- designation of the NPS listing potential suitable sites for new nuclear development.

b) Site Selection

A.3.41 The sites listed in the NPS, therefore, have been assessed by the Government by way of a Strategic Siting Assessment (SSA) and an Appraisal of Sustainability (AoS), which has assessed the sustainability of the NPS on nuclear power generation, taking account of potential alternative strategies and the potential impacts of nominated sites.

A.3.42 The SSA criteria for site assessment were based upon selected exclusionary and discretionary criteria. Exclusionary criteria were those which, if breached, would categorically exclude all or part of a site from further consideration (for example demographic risk or proximity to certain military activities). Discretionary criteria were those criteria that the Government considered, for various reasons, could, either singly or in combination, make all or part of a site unsuitable for a new nuclear power station but which needed to be carefully considered in order to come to a conclusion as to the site's strategic suitability (for example, flood risk and proximity to hazardous facilities).

A.3.43 The outcome of the AoS was published in November 2009 *(Appraisal of Sustainability of the draft nuclear National Policy Statement: Main Report).* The AoS concluded that the preferred approach should be the preparation of a Nuclear NPS, based on the case for nuclear in relation to other alternatives (para. S.8.7). The AoS reviewed the sustainability characteristics of the potentially suitable new nuclear sites then proposed to be identified in the draft NPS and identified key issues that were recommended to be identified for the IPC to consider when determining individual applications for nuclear power stations. For Hinkley Point C, its findings were consistent with those of the SSA. Of particular relevance to Hinkley, the AoS identified (para. S.12.7):

- that there is some potential for adverse effects on the settings of four national and internationally protected sites, on water quality and on fish/shellfish populations;
- potential adverse effects on views from the Quantocks AoNB, which would be difficult to mitigate; and
- likely positive long term economic and employment effects in the region.

Annex C to NPS EN-6 contains the outcomes of the individual site assessments referred to above. The Annex provides the results of the assessment of the nominated Hinkley Point C proposal against the SSA criteria which reflects advice from specialists and the regulators [1].

Table A.1: Strategic Siting Assessment

SSA Criteria	Summary of Assessment
Deployment by end of 2025	Passes
Demographics – "semi-urban" criteria	Passes. Support from HSE.
Proximity to military activities	Passes. Notes possible effects on Bridgwater Bay Firing Area.
Flooding, storm surge and tsunami	Passes. Low risk of flooding, including allowances for climate change, storm surge, and tsunami.
Coastal processes	Passes
Proximity to hazardous facilities	Passes
Proximity to civil aircraft movements	Passes
Internationally designated sites of ecological importance	Passes – noting possible effects on Severn Estuary SAC, SPA, Ramsar, and to a lesser extent the River Wye SAC and the River Usk SAC
Nationally designated sites of ecological importance	Passes – noting possible effects on Bridgwater Bay NNR, Bridgwater Bay SSSI, Seven Estuary SSSI, and to a lesser extent the River Wye SSSI, River Usk SSSI
Areas of amenity, cultural heritage and landscape value	Passes – noting possible effects on Quantock Hills AONB and public footpaths on and around HPC Development Site
Size of site to accommodate operation	Passes
Access to suitable sources of cooling	Passes
Health impacts	Passes
Meteorological conditions	Passes
Cumulative Effects (with Oldbury)	Passes – subject to detailed cumulative assessment of proposals that elsewhere emerge.

Source: Summarised from NPS EN-6, June 2011, Annex C

A.3.44 The SSA process involved a strategic level review of the suitability of the Hinkley Point C site against a number of criteria. Fundamentally the process was influential in confirming the potential suitability of the Hinkley Point C site in principle for the development of a new nuclear power station.

A.3.45 The process also produced useful information which can be used in the spatial development of the project. Lessons learned from the SSA which help inform the project's development and acceptability include:

[1] Health and Safety Executive including the Nuclear Installations Inspectorate and Office for Civil Nuclear Security, Environment Agency, Civil Aviation Authority, Ministry of Defence, Department of Transport, Atkins Ltd, MWH Enfusion

- A Flood Risk Assessment (FRA), of course, will be necessary to support any application. In principle, the AoS established that mitigation against flooding may be possible through appropriate design and construction of defences and suitable management (C.5.22), whilst the Environment Agency advised that any new flood mitigation measures are unlikely to have a detrimental effect on the flood risk to the surrounding area (C.5.29). Nevertheless, as part of any site licensing conditions, the licensee must review their safety case at regular intervals (typically on a 10 yearly basis) taking account of the most recent climate change projections and allow any necessary modifications to flood defences and operating arrangements to be undertaken (C.5.26).
- The effects of coastal erosion should be mitigated through appropriate design and construction of defences, taking into account the potential effects of ‘coastal squeeze’ (paragraph C.5.35).
- The Habitats Regulations Assessment concluded that, at a strategic level, it could not rule out the potential for adverse effects on the integrity of European Sites. The HRA proposed a suite of avoidance and mitigation measures to be considered as part of any project level HRA (C.5.49). Similar conclusions are identified in relation to nationally designated sites of ecological importance (C.5.57).
- The Appraisal of Sustainability identified potential adverse effects on the surrounding elevated local landscape and associated distant views with potentially lasting adverse effects on the setting and views from the Quantock Area of Outstanding Beauty to the West (C.5.60). Whilst some mitigation may be put in place, the Appraisal of Sustainability considered that the main form of mitigation potential may be the clustering of new and proposed reactor buildings to avoid broadening the potential visual impact – even so, the Appraisal of Sustainability noted that a new nuclear power station at Hinkley Point C is likely to lead to perceptible deterioration in some of these views (C.5.62).
- Potential effects on local rights of way and, particularly, the coastal path were identified along with possible mitigation measures which may include siting certain elements of the development away from public footpaths, as well as the provision of realignments to existing or planned rights of way (C.5.63).
- Any nuclear reactor must not be sited east of longitude grid reference 32128 as the area is of inadequate size to provide defence-in-depth for a reactor and its associated turbine hall, spent fuel and intermediate level waste stores (paragraph C.5.70).
- Cumulative impacts, if the proposed site at Oldbury is developed for nuclear power generation, should be assessed, particularly with regard to effects on European Sites (paragraph C.5.83).
- Development at Hinkley Point was appraised as having positive effects of regional economic significance on employment and community viability and

indirect positive health effects associated with enhanced prosperity and long term employment opportunities, although this will only be significant for local communities if employment is secured for local people (C.5.85).

A.3.46 As a result of these and other assessments, NPS EN-6 confirms:-

> *"2.3.2 The Strategic Siting Assessment was designed to identify sites in England and Wales that are potentially suitable for deployment of new nuclear power stations by the end of 2025.*
>
> *2.3.2 Having considered all of the sites nominated as well as those identified by the Alternative Site Study, the Government believes that only those sites listed in part 4 of this NPS are potentially suitable for the deployment of new nuclear power stations in England and Wales by the end of 2025.*
>
> *2.4.3 As a result of the SSA and the Alternative Site Study, the Government does not believe that there are any alternatives to the listed sites…"*

A.3.47 Accordingly, Hinkley Point is listed as one of 8 "potentially suitable sites" in Part 4 of NPS EN-6. The NPS explains (page 9) that the SSA could only conclude that sites are "potentially" suitable as it is a strategic level assessment based on the information available to the Government at the time. In accordance with the Planning Act 2008, the IPC will assess the details of each application for new nuclear development in accordance with NPS EN-1, EN-6 and any other matters which it considers relevant and important, in order to determine whether or not to grant development consent at any of the listed sites.

A.3.48 Not all sites nominated were accepted into the NPS. As a result of the SSA and AoS exercises, sites at Braystones, Kirksanton and Dungeness were not found to be potentially suitable and were not considered to be feasible alternatives.

A.3.49 It is significant that national policy has identified the potential suitability of Hinkley Point C for new nuclear development notwithstanding the SSA findings that its development could generate some significant adverse effects. Of these, perhaps the most significant is a recognition that the development of a new nuclear power station at Hinkley (and indeed at the other 7 potentially suitable sites) could have adverse effects on European designated sites. Paragraph 1.8.2 of NPS EN-6 explains that, as a result, the Government has considered potential alternatives that would better respect the integrity of European protected sites but concluded that there are none. Accordingly, the Government has presented a case for Imperative Reasons of Overriding Public Interest (IROPI) which sets out why the NPS should proceed. This is set out at Annex A of the NPS, which confirms that:

> *"A.3.7 There are IROPI in providing new nuclear generating capacity in order to provide our future energy security in a way which minimises carbon emissions, thus securing public safety, public health and combating climate change, which is a beneficial consequence of primary importance to the environment."*

A.4 The Site Preparation Application

A.4.50 The planning history of the main site is also important as a result of recent applications. In particular, planning permission has been granted for initial enabling works, including the removal of a soil mound and the relocation of a helipad in order to facilitate the construction of Hinkley Point C. More significantly, two substantial **preliminary works applications** have been submitted :-

- an application for the necessary consents and powers to construct and operate a Temporary Jetty and associated works (the Jetty applications) which have been made to the Marine Management Organisation (MMO) and the Department of Energy and Climate Change (DECC); and
- a planning application submitted to West Somerset Council (WSC) on 26th November 2010 for **site preparation works** (application reference 3/32/10/037).

A.4.51 **The jetty applications** are to be the subject of a public inquiry in November 2011 and, if approved, would permit its early construction and operation. The jetty would be used to bring at least 80% of aggregates for concrete to the site and has the facility to bring additional construction material, thereby saving approximately 250,000 lorry movements on local roads.

A.4.52 Whilst the jetty is the subject of these separate applications, at the time of submitting the draft DCO application, the outcome of that process is not known. Accordingly, EDF Energy is also seeking consent for a temporary jetty and associated conveyor and pipeline as part of the DCO, with the offshore works included in Part 2 of the draft Order. In the event that EDF Energy's HEO and TWAO jetty applications are granted and safe from legal challenge, EDF Energy will withdraw its request for the IPC to grant Part 2 of the draft DCO. EDF Energy will, however, continue to seek the power to close the temporary jetty via the DCO if this power is not granted in the HEO.

A.4.53 The purpose of the **site preparation works** is to clear the application site and undertake the earthworks necessary to create the development platforms required for the subsequent construction of Hinkley Point C power station. In addition, works would commence on the deeper excavations for building foundations. The site preparation works also involve substantial drainage works, including culverting Holford stream, which runs through the centre of the site, and the construction of a network of spine drains for the collection of surface water and ground water In addition to the earthworks and site drainage, the application includes a number of supplementary packages of work including:-

- demolition of existing barns;
- vegetation clearance;
- erection of boundary and construction fencing;
- construction of a temporary retaining wall along a low point in the cliff fronting the application site (to enable land raising of the site during platform development);
- construction of two new access points on the C182, each with its own roundabout, and internal site haulage routes;
- construction of two concrete batching plants;
- installation of services infrastructure, including a temporary 11kV sub station;
- local switch rooms and other utilities; and
- mobilisation of the civil works contractor, ie the contractor that would undertake the civil works upon grant of the DCO for Hinkley Point C.

A.4.54 In other words, the application seeks permission for those aspects of site clearance and preparation that can reasonably be undertaken before development consent is obtained for the construction of the nuclear power station itself.

A.4.55 In principle, the early approval of preparatory works for nuclear power stations was endorsed in a letter issued jointly by DECC and DCLG dated 16 July 2009. That letter encouraged local authorities to have confidence in considering such applications on their merits but recognised that authorities may decide that consent for such development should potentially be granted on the basis that any preliminary works carried out will be removed if the subsequent application to the IPC is turned down or not pursued for other reasons. That is the basis on which the site preparation works application was made to West Somerset Council, ie that the land would be reinstated in accordance with a Landscape Mitigation and Reinstatement Strategy in the event that development consent for the construction and operation of a nuclear power station at Hinkley Point is not granted within 5 years of the date of the site preparation planning permission.

A.4.56 The site preparation application was considered by the Planning Committee of WSC on 28 July 2011 when Members resolved to approve the application in accordance with the officer's report subject to a series of conditions and Section 106 obligations. At the time of drafting this Planning Statement, the Section 106 agreement had not yet been signed.

A.4.57 The officer's report on the application recognised that:-

- the national imperative of timely delivery of new nuclear power stations (page 327) and that a significant material consideration in the determination of the application is the identified need for new nuclear generating capacity to be operating as quickly as possible (page 348);
- there will be a loss of best and most versatile land but it is considered that other material considerations would outweigh the effects of this loss (page 173);
- local footpaths, which are an important part of the local recreation resource, will be adversely affected by the proposals but, through the provision of mitigation and financial contributions secured by Section 106 obligations and conditions, the proposals can be considered to be generally compliant with development plan policy (page 195);
- in relation to landscape and visual impacts, the approach taken by the applicant will assist in managing and minimising some of the individual and cumulative visual impacts associated with the site preparation works, although great reliance is placed on the ability of a tree screen and shrub planting to provide an effective visual screen across an extensive area and to mitigate lighting intrusion. Nevertheless, given the major changes to the landscape, not all the effects can be satisfactorily mitigated through design, siting or through visual screening of the site. For instance, the Council concurs with the views of the Quantock Hills AONB Service that the visual impacts on the elevated areas of the AONBs cannot be sufficiently mitigated through screening and design and with the views of the Fairfield Estate that the impacts on the Area of Outstanding Scenic Interest cannot be fully mitigated. Therefore, it is necessary to secure contributions to off site landscape improvements and enhancements as set out in the recommended Heads of Terms for the Section 106. On this basis, the proposal could be regarded as complying with some development plan landscape and visual policies but where conflicts exist, the Council has concluded that there are other material considerations including national policy which outweigh the conflict (page 241); and
- in relation to heritage issues, irreversible harm will be caused to buried archaeological remains in conflict with national and local policy and there may be impacts on the sensitive historic environment of the area. Planning conditions and mitigation will assist to some extent in compensating for the loss of heritage assets. Nevertheless, it will be difficult to mitigate against all of the harm on the historic environment and there will be residual impacts that could result in conflict with development plan policies. Where these conflicts exist, the Council has concluded that there are other material considerations which outweigh the conflict (page 241).

A.4.58 Other conclusions were reached on specific topics and the overall conclusion was to recommend approval subject to detailed conditions and Section 106 obligations.

A.4.59 In addition, through negotiation, EDF Energy and the Local Planning Authorities took the opportunity to include within the Section 106 agreement a number of matters which could be usefully put in place early to help the local area accommodate more easily the development of Hinkley Point C itself. More detail is provided in Section 9 of this Statement but, in principle, implementation of the site preparation planning consent would put in place obligations on EDF Energy to provide:

- advance highway improvement works;
- advance investment in new education and training facilities;
- the establishment of a Housing Fund to provide advance mitigation from any adverse effects on the local housing market from the rapid influx of construction workers in the early years of construction;
- investment in leisure facilities to anticipate the impacts and demands of the main DCO proposals;
- off site landscape and ecological enhancements to mitigation the visual and nature conservation impact of both the site preparation and main power station works; and
- a series of economic development initiatives to help prepare local companies and the local workforce for business and employment opportunities at Hinkley Point C.

A.4.60 There are at least three important consequences of the site preparation application which can be identified now that it has been supported by WSC ie:-

- up to date local endorsement that the principle of the development of the main site is acceptable in planning terms because of the national importance of Hinkley Point C;
- site preparation provides the ability to accelerate the development of Hinkley Point C; and
- the site preparation Section 106 agreement would put in place measures which, if implemented, would reduce the impact of the main DCO proposals.

A.5 Conclusions

A.5.61 Whilst all impacts and effects of the DCO proposals fall to be considered on their merits against relevant policy tests, the planning history includes relevant considerations which support the principle of the current proposals. In particular, not only has the principle of a nuclear power station at Hinkley Point C been endorsed in a previous planning decision, a more recent and up to date planning resolution has endorsed the in-principle acceptability of the development of the site for preparatory works, in view of the national imperative to deliver the nuclear power station.

A.5.62 The effect of the resolution to approve site preparation works is also to establish the acceptability of the principal land based impacts of the development, including impacts on archaeology, ecology, agricultural land, public rights of way and, if permission is granted, to allow EDF Energy to put in place relevant mitigation to address those impacts and to prepare for the power station development itself.

A.5.63 Even more significantly, the potential suitability of the site for the development of a new nuclear power station has been endorsed in Government policy as a result of a systematic assessment process.

A.5.64 None of this background predetermines the acceptability of the DCO application. Government policy has, however, established the potential suitability of the site for a new nuclear power station, in full recognition of the likelihood that its development may generate some adverse impacts. The site preparation planning application and the support for that application from the local authority reinforces that in-principle suitability and also demonstrates that the impacts at least of the site preparation works are acceptable, subject to the provision of appropriate mitigation.

A.5.65 This background provides a strong foundation against which to consider the DCO proposals themselves.

B. SUMMARY OF THE PRINCIPAL MITIGATION OBLIGATIONS PROPOSED AS PART OF THE DCO APPLICATION (SECTIONS 7-9 OF PLANNING STATEMENT)

B.1 Planning Analysis: Project-Wide Considerations

B.1.1 NPS EN-1 and EN-6 identify "*Generic Impacts*" and "*flags for local consideration*". Whilst these are not exhaustive, they provide a helpful guide to the principal issues which the IPC is expected to take into account when determining the acceptability of a DCO application for a nuclear NSIP. The majority of the impact headings relate to site-specific considerations – such as landscape and visual impact, heritage impact etc but others are related to project-wide effects and are considered in this section of the Planning Statement. Section 8 considers site specific environmental and other effects and reviews the planning issues raised by the individual sites which collectively make up the HPC project.

B.1.2 In particular, the NPSs identify the need to consider impacts relating to the following:

- socio-economic effects;
- human health and well-being;
- traffic and transport.

B.1.3 Each of these topics is the subject of its own detailed assessment. The purpose of this Planning Statement, therefore, is to draw from those assessments and to put their conclusions into the context of the policy tests set by the NPSs. In each case, it is important to identify whether there are adverse impacts which it is relevant to take into account when considering the overall planning balance. In other words, whether there is a combination of adverse effects which is sufficient to overcome the strong presumption in favour of granting consent set out in NPS EN-1 (para. 4.1.2).

a) Socio-Economic Effects

B.1.4 The HPC DCO application meets the requirement of NPS EN-1 (para. 5.12.2) that the applicant should undertake and include in their application an assessment of socio-economic effects. Chapter 9 of each volume of the **Environmental Statement** addresses the socio-economic effects of the development in comprehensive terms – and, particularly, in the main development site volume. In addition, the application is supported by a number of relevant strategies and by an **Economic Strategy,** which are all relevant under this heading.

B.1.5 NPS EN-1 and EN-6 advise that the socio-economic topic should consider issues relating to:

- the creation of jobs and training opportunities;

- the provision of additional local services and improvements to local infrastructure;
- effects on tourism;
- the impact of a changing influx of workers during the different construction, operation and decommissioning phases on the demand for services and facilities in nearby settlements, including effects on social cohesion;
- economic benefits; and
- cumulative effects.

B.1.6 These matters are addressed in detail in the Social Economic Chapters of the **Environmental Statement**, based on a thorough evidence base. Sound evidence is important for these purposes because NPS EN-1 advises:

> *"5.12.7 The IPC may conclude that limited weight is to be given to assertions of socio-economic impacts that are not supported by evidence….."*

B.1.7 The Site Assessment contained at Annex C of NPS EN-6 identifies that development at Hinkley Point C has been appraised in the preparation of the NPS as having positive effects of regional economic significance on employment and community viability (para.C.5.85). Nevertheless, consultees including the local planning authorities have expressed concerns about some of the potential effects of the HPC project including, for instance, its impact on local housing, community cohesion and tourism.

B.1.8 EDF Energy has taken comprehensive steps to understand and assess these issues. In particular, a formal Socio-Economic Working Group was established in October 2010, incorporating representatives from SDC, WSC, SCC and EDF Energy. The Working Group has met on multiple occasions to commission and share data. A series of six detailed technical notes have been prepared by EDF Energy for consideration by the Working Group and are appended to the Socio-Economic chapter of the **Environmental Statement.** They are as follows:

- Technical Note 1: Workforce Profile;
- Technical Note 2: Demographic Benchmarks;
- Technical Note 3: Spatial Distribution;
- Technical Note 4: Accommodation Datasets;
- Technical Note 5: Leisure Audit and Estimated Demand;
- Technical Note 6: Community Cohesion.

i. Employment and Economic Effects

B.1.9 The socio-economic assessment considers the potential effects of the project at a number of geographic scales including:

B.1.10 Construction Daily Commuter Zone (CDCZ) – a 90 minute commute time within which home-based workers would be drawn to employment at Hinkley Point C without moving house;

B.1.11 60-minute travel time – the estimated extent of daily travel time to HPC by non-home based workers who may move into the area to work on the project.

B.1.12 In addition, a study area is formed from the administrative areas of West Somerset, Sedgemoor and Taunton Deane, whilst other effects are considered at a more local level.

B.1.13 The baseline demonstrates that recent years up to 2008 saw a relatively strong growth in employment in Somerset and in Sedgemoor in particular but with significant local variation, including less strong growth in West Somerset and a decline in Bridgwater. The County Council's Local Economic Assessment notes that Somerset performs poorly in terms of employment in knowledge intensive industries and has an over-dependency on sectors that are at risk of decline, including sectors such as food and drink, tourism, manufacturing and sectors that are based on public spending. Forecast declines in agriculture and fishing will have an impact on rural areas in Somerset, whilst the forecast decline in manufacturing is likely to impact larger centres such Yeovil and also Bridgwater.

B.1.14 A major issue threatening the economy, especially in the short to medium term is the effect of public sector expenditure cuts. Sedgemoor and Taunton Deane have a significant reliance on the public sector, with 31.1% and 29.8% of all residents employed in public sector positions. Independent reports by the South West Observatory[1] and by Experian[2] both identify concerns for the resilience of the local economy.

B.1.15 One of the strengths of the regional economy has been its contribution to the UK's nuclear work force, with the south west hosting approximately 35% of the country's employees in the sector. However, the decommissioning of Oldbury and of Hinkley B will result in a 45% reduction in work force employed in the sector in the south west by 2025. Against this background, it is unsurprising that local strategies recognise the importance of the Hinkley Point C inward investment. Endorsement for the importance of the investment has come from a range of sources including the following:

B.1.16 the recently formed Heart of the South West Local Enterprise Partnership published a Partnership Prospectus in March 2011 which identified a number of key priorities, including encouraging investment in potential growth sectors such as low carbon energy generation that can create and sustain new private sector jobs, rebalancing the economy away from an over-reliance on the public sector (Socio-Economic Assessment para 9.1.80);

B.1.17 the non-statutory Somerset County Plan – (2010-13) sets out the County Council's priorities. On *prosperity* the plan notes that Somerset has historically under performed economically, so it aims to help existing businesses grow and to attract

---

[2] http://www.bbc.co.uk/news/business-11233799

new ones. It identifies the development of HPC as a "*huge opportunity*" (Socio-Economic Assessment para 9.1.91);

B.1.18 SDC's recently updated Economic Development Strategy 2011 – 2026 confirms that:

> *"the proposed multi-billion pound investment by EDF Energy in a new nuclear power station at Hinkley Point C represents a substantial potential benefit on the local economy and area. This provides the local authority and public sector with the opportunity to work with the local community and businesses to mitigate any adverse impacts during construction and to capitalise upon the investment to embed lasting economic benefits in Sedgemoor." (Socio-Economic Chapter para 9.1.02).*

B.1.19 Against this background, it is unsurprising that the Socio-Economic Assessment identifies a number of beneficial impacts of Hinkley Point C – both during construction and operation. The headline impacts include the following:

- **During Construction** – 25,000 person years work, which is expected to result in 20,000-25,000 different individual posts in the main 108 month construction period, with a peak headcount of 5,600.
- Opportunities for the local supply chain are expected to be at least £45m per annum, wages and multipliers are estimated at £85m per annum or just under £800m over the construction period (Economic Strategy para 4.1.4).
- **Operation –** 700 direct EDF employees and up to 200 contract staff – totalling 900. The contractor support will also increase significantly to over 1,000 for two months periods during each unit's refuelling outage (every 18 months). (Socio-Economic Assessment para 9.1.226).
- Long-term wages of £30m per annum and additional supply chain benefits of £40m per annum (Economic Strategy para 4.1.4).

B.1.20 The scale of these benefits represents a major opportunity to support local communities and stimulate the local economy. It also offers real opportunities to tackle worklessness which has increased in recent years to the point where there are more than 19,000 unemployed or economically inactive residents in Somerset, of whom 7,000 live in Sedgemoor (Economic Strategy Table 5).

B.1.21 EDF Energy's Vision for the HPC project includes a determination to ensure that the inherent benefits of its investment in Hinkley Point C are captured in a way which maximises its practical contributions to the local and regional economy. Accordingly, EDF Energy is committed to a number of strategies to ensure that maximum local benefit is gained from its investment at Hinkley Point. In particular, EDF Energy has committed to a **Construction Workforce Development Strategy** (CWDS) which comprises seven key projects:

- **Employment Brokerage**: The project has been developed with JobCentre Plus and will match vacancies with contractors to residents. This will include people who already have appropriate skills, and also identify and address skills needs and barriers to work for target groups including the unemployed and young people not in education, employment or training (NEETs). Partners will seek to lever in external funding to support customised training to address identified needs. EDF

Energy and Jobcentre Plus are committed to providing staffing resources for this project.

- **Employment Outreach**: Employment outreach projects will engage with local communities, particularly hard to reach groups, so that they are aware of opportunities at HPC and supported in gaining the necessary motivation and skills to access jobs. EDF Energy is funding community outreach workers in Sedgemoor and West Somerset who will liaise with their own outreach co-ordinator. They will identify specific interventions relating to clients' needs and will link with the brokerage service.
- **Construction Skills Centre**: EDF Energy has been working in partnership with Bridgwater College to enable local, demand led training to be delivered at a Construction Skills Centre in Cannington. The centre will be able offer courses ranging from basic health and safety and card schemes through to advanced training in specific skills. This will include a dedicated Civil Engineering site designed to accommodate state of the art training in all types of plant being used at HPC, OSAT NVQs, Building Services/Utilities, Formwork, Steel Fixing, Steel Erecting, New Roads and Street Works.
- **Constructionarium**: This is a hands-on construction experience for students following civil engineering and built environment courses. It allows the students to learn practically from industry - their future employers. It is designed to be part of a 21st Century engineering education which links academic theory with contractors and consultants from the construction industry. It will be established in partnership with education providers and based at the Construction Skills Centre.
- **Hinkley Skills Ready Project**: This will enable residents of West Somerset to get the skills they need to work at HPC. It has been developed in partnership with West Somerset Community College, and will combine physical investment in buildings at the college with a curriculum designed to meet the needs of HPC contractors.
- **Apprenticeships**: EDF Energy aims to at least meet the national benchmark for construction apprenticeships. EDF Energy will produce a specific Apprenticeship Strategy and work with its supply chain and other agencies to maximise apprenticeships for local residents.
- **The Enterprise Centre Project**: EDF Energy is working with West Somerset Community College and West Somerset Council on a feasibility study for an enterprise centre project, to support Somerset residents and businesses in providing services to the incoming workforce and prepare for other new markets (eg. visitors and tourists) that may arise as a result of the HPC development.

B.1.22 The commitment is defined in the **Heads of Terms for the Section 106 Agreement** which is discussed in Chapter 9 of this Planning Statement. The implementation of the strategy is being overseen by a governance structure that includes key partners. It includes Key Performance Indicators that will be regularly monitored, so that the effectiveness of projects can be assessed and reviewed over the lifetime of the development.

B.1.23 The potential to secure benefits locally is also enhanced by the HPC **Local Business Engagement Strategy**, which is annexed to the **Economic Strategy**. The Strategy confirms that EDF Energy has been working with the Somerset

Chamber to Commerce for some time now in order to ensure that not only the UK supply chain but also the local supply chain benefit from involvement in the project. The strategy includes:

- building a database of Somerset suppliers, certificated as meeting the necessary quality standards for engagement on the project;
- undertaking a series of visits to local suppliers in order to explain the project requirements and ensure that they are "Hinkley ready";
- hosting a series of "meet the buyer" events, introducing local suppliers to potential principal contractors;
- engaging with local business organisations to raise the profile and the opportunities generated by the Hinkley Point C project; and
- adopting Key Performance Indicators aimed at maximising benefits for local companies.

B.1.24 These comprehensive measures secure EDF Energy's Vision to maximise the inherent benefits of the project locally. The potential benefit of the project, however, is even greater because of its capacity to act as a catalyst for change. Chapter 5 of the **Economic Strategy** explains how the Government has identified new nuclear investment as an opportunity to bring about structural change in the national, regional and local economies.

B.1.25 The particular additional benefit which the HPC project may be able to facilitate is the potential to establish a Low Carbon Business Cluster in Somerset. As early as June 2009, the South West Regional Development Agency (SWRDA) identified the potential for Hinkley to become *"a source of international expertise and create a strong high value business cluster in Somerset*"(ES **Volume 2, Chapter 9 Socio-Economic Assessment** para 9.1.79). This ambition is now a central objective of Somerset's Local Economic Assessment (p.5) and of Sedgemoor's Economic Development Strategy (Section 5.5 and **Table 7**). SDC is bringing forward employment land which could benefit from the opportunity and EDF Energy is working with the Councils, funding research to support the Somerset Low Carbon Economic Delivery Plan. In addition, EDF Energy has committed itself to a £3m investment in the new Energy Skills Centre at Bridgwater College which could become a regional or even national centre for excellence for the teaching of sustainable energy techniques and alternative energy innovations.

B.1.26 Against this background, the potential adverse economic and employment effects are extremely limited. In fact, the only potential adverse effects which have been raised through consultation areas follows:

- displacement effects, ie the loss of labour from existing local companies to Hinkley Point C;
- congestion impacts on the agricultural and logistics sectors; and
- adverse effects on the tourism economy.

B.1.27 These issues are addressed in detail in the **Socio Economic Assessment** and potential transport effects are addressed in the **Transport Assessment**; no adverse impacts on these issues are identified. Experience at Sizewell B was that around

30% of employees recruited in the peak recruitment year had come from other local employers but a survey of 160 local companies found that less than 10% of those companies thought that the power station project had made it more difficult to retain or recruit staff (para 9.1.386). If similar proportions arose at Hinkley this would account for 3% of the construction workforce in Somerset and 1% in the CDCZ, which would be negligible in the context of the overall "churn" within the construction and the overall labour market in the area.

B.1.28 There is no evidence that the construction and operation of a nuclear power station has adverse impacts on tourism. During the construction period, the incoming construction workforce is expected to make a major contribution to the tourist accommodation sector, particularly by taking up substantial spare capacity available in the off peak seasons. Expenditure in tourist accommodation over the lifetime of the project is estimated at around £15m.

B.1.29 A new Public Information Centre is proposed as part of the HPC project. It is the intention of EDF Energy that this will be open to the public with a mix of local, tourist and educational visitors. The centre would provide information not only on the HPC project but also wider Somerset attractions. EDF Energy intend to have an initial cap of around 250,000 annual visits per year with capacity for up to 1,000 a day in the August peak. The centre would provide an important additional indoor attraction for the area. If it is as successful as expected, it would be the most popular visitor attraction in Somerset and would have a major beneficial effect at a local and county level.

B.1.30 In reality, the investment in Hinkley Point C provides an important opportunity to rebalance the local economy and to tie the sub-regional economy into two of the few genuine growth sectors – infrastructure construction and low carbon energy. The investment and activity planned in construction workforce and local procurement initiatives would ensure that these opportunities are captured locally.

B.1.31 EDF Energy's assessments confirm the expectation in the NPS that the development of Hinkley Point C would have positive employment and economic effects of regional economic significance.

ii. Education

B.1.32 Education issues arise in two ways: EDF Energy has an education strategy which seeks to maximise the opportunities for young people created by the HPC project. In addition, however, it is also important to ensure that there is no adverse effect on local education facilities from the influx of HPC workers.

Education Strategy

B.1.33 The *Inspire* Education Strategy forms an appendix to the **Economic Strategy**. It sets out a comprehensive commitment to work in and with schools in Somerset to engage and inspire young people to follow a pathway in Science, Technology, Engineering and Mathematics, with a primary aim of raising aspiration and attracting school leavers into careers in construction or engineering. The *Inspire* strategy is fully funded through the **Section 106 Heads of Terms** and EDF Energy has recruited a specialist team to implement it. Activities will include the production of information packs, curriculum and teacher support, site visits, classroom support, careers events, an online environmental education tool, specific training and support, expert visits to schools and virtual work experience. The strategy can be seen as the first part of a comprehensive education and training programme aimed at maximising local opportunity and it complements the activities explained above in the **Construction Workforce Development Strategy**. Over a fifteen year period, the HPC project is expected to generate 700 apprentice and 150 graduate opportunities per annum and it holds the potential to transform the lives of hundreds of young people in the local area.

Education Impacts

B.1.34 In order to ensure that there are no adverse impacts on education capacity in the local area, the socio-economic assessment considers in detail the potential scale of demand from Hinkley Point C construction worker's children relative to capacity in local schools (**Socio-Economic Assessment** para 9.1.484 onwards). The **Heads of Terms for the Section 106 Agreement** propose advanced mitigation through early investment funded by EDF Energy in primary school capacity in Bridgwater and Cannington and a formula for payment towards increasing education capacity if monitoring identifies further impacts beyond existing capacity. The proposals would more than mitigate the assessed minor impact which has been assessed from the central assumptions set out in the Socio-Economic Assessment.

iii. Accommodation

B.1.35 Whilst NPS EN-1 and EN-6 do not specifically flag the need for the IPC to consider potential effects on the local housing market, effects relating to the influx of workers during the construction and operational phases are identified as relevant. In addition, the local authorities have continued to express concern about the potential impact of Hinkley Point construction workers on the local housing market. In particular, concerns have been expressed that the demand for workers could adversely affect the tourism accommodation sector and that the influx could raise prices and rents, which could in turn make access to accommodation more difficult for those on the lowest incomes. Accordingly, these considerations have been the subject of extensive engagement with the local authorities.

B.1.36 Again, a detailed evidence base is available, which is reported in the Socio-Economic Chapters of the **Environmental Statement**. As listed in paragraph 7.2.4, Technical Notes 1 and 2 (appended to the Socio-economic assessment Volume 2 Chapter 9 of the ES) relating to workforce profile and demographics have been prepared by EDF Energy and have been agreed by the Local Authorities. This provides a helpful basis against which to consider the potential for adverse effects.

B.1.37 The Technical Notes explain the agreed assumptions that the construction workforce will peak at 5,600 workers and that the best central estimate is that 34% of these would be home based workers, with 66% or 3,700 workers coming to the area and requiring accommodation (non home based workers or NHB) at peak. Those workers are expected to seek accommodation within a 60 minute drive time. Detailed research has been undertaken to estimate the capacity of accommodation within that 60 minute drive time.

B.1.38 The evidence also demonstrates that the area has a relatively mobile population. On average, 7% of households move home each year and the figure rises to 20% within the private rented sector (PRS). This may be partly due to the nature of the local economy, which relies in part on traditionally seasonal sectors such as tourism and agriculture.

B.1.39 In relation to tourism, it is estimated that the area has approximately 35,000 tourist bed spaces excluding accommodation in holiday villages which is unlikely to be available to HPC workers. EDF Energy's estimates of available capacity have been cautiously made in order to ensure no adverse effect on the tourist sector. In particular vacancy rates have been examined. August is the peak month and vacancy rates show only 6,500 vacancies. At other times of the year, capacity is much greater with typically 24,500 vacant bed spaces in March (see the **Accommodation Strategy Table 4.3**). EDF Energy's capacity estimates are further reduced to discount accommodation which may not be affordable to workers, leaving an estimate of 2,070 spare bed spaces in the peak month of August in the 60 minute drive time.

B.1.40 This is the extent of tourist accommodation which EDF Energy believes can be available for take up by HPC workers without any risk of adverse impacts.

B.1.41 Similar estimates have been made of the private rental sector. Within the 60 minute study area, there are 22,000 PRS units. Many of these have capacity for more than one bed space, so that the PRS sector is expected to have a capacity of 51,000 bed spaces in the 60 minute travel time. Based on an analysis of vacancy rates, it is estimated that at least 1,270 bed spaces are surplus within the study area. This is a particularly conservative estimate which relies only on spare capacity above normal vacancy rates. (see the **Accommodation Strategy Table 4.6**).

B.1.42 Other sources of accommodation are the owner occupied sector and latent accommodation. These have the following characteristics:

- The demand for owner occupied accommodation is expected to be limited, principally to managerial and professional grades who move to longer term construction jobs at Hinkley, a number of whom may be expected to bring their families. The **Socio-Economic Assessment** estimates that these would account for approximately 500 workers with families. No issue appears to be alleged in relation to the impact of those workers on the owner occupied market. Their impact on the market would equate to a maximum of 3% of all property sales, benchmarked against sales in 2009, which was a relatively low year for house sales. This demand may provide a small stimulus for the market but is not alleged or expected to have adverse impacts.
- The latent sector represents potential capacity that is not being currently or previously rented. This comprises rooms which local homeowners are willing to rent out to Hinkley construction workers. To test the market, EDF Energy has placed adverts locally seeking interest from homeowners and received a strong response. The most recent advert resulted in 750 responses of which over 400 were genuinely "additional" to existing supply. Interest has continued to grow and the HPC Accommodation Office database accounted for 1,500 properties at September 2011 of which 400 are rooms within peoples houses.

B.1.43 In addition to this supply, EDF Energy proposes the construction of 1,510 bed spaces in three workers accommodation campuses – at the HPC development site, at Bridgwater A and at Bridgwater C. Any planning issues related to the campuses themselves are discussed further in Section 8 of this Planning Statement but, taken together with the estimates of supply in the existing accommodation market, the availability of the campus accommodation brings the potential supply of accommodation available to workers to at least 5,740 spaces. Comparing this to the likely take up of different accommodation types, the **Accommodation Strategy** estimates the relative supply and demand of accommodation to be broadly as follows:

Table B.1: Hinkley Point C Accommodation Capacity and Expected Take-Up

Type	%	Number	Capacity
Campus	39%	1,450	1,500
Tourist Accommodation	16%	600	2,070
Private Rented	20%	750	1,270
Owner Occupied	14%	500	500+
Latent Accommodation	11%	400	400+
TOTAL NHB		3,700	5,740

B.1.44 The take up of campus, owner occupied and latent accommodation would have no adverse impacts on the housing market, although the overall demand is expected to stimulate the market and, for instance, generate investment in new building, bed and breakfast and latent accommodation.

B.1.45 Concerns for potential impacts, therefore, should be limited to tourist accommodation and the PRS.

Tourist Accommodation

B.1.46 The available information, however, suggests that there are no likely adverse impacts in the tourism sector for the following principal reasons:-

- the estimated take up of tourist accommodation (600 bed spaces) compares to a very cautious estimate of capacity of 2,070 spaces. It should be remembered that this estimate is a sub-set of a total vacancy of more than 6,500 bed spaces and that this is the vacancy rate in the peak summer month of August. In the lower seasons, available accommodation peaks at over 20,000 bed spaces;
- the take up estimate represents the peak of the HPC construction workforce. Figure 2.2 in the **Accommodation Strategy** shows that the number of non-home based workers exceeds 3,000 for only an 18 month period and that the peak itself is short-lived; and
- there is no evidence, therefore, that there would be any adverse effect even in the Summer peak on tourist accommodation. Instead, a more realistic assessment would be that HPC construction workers would bring significant benefit to the tourist accommodation sector by providing year round demand in an industry which is subject to extreme seasonal variation.

Private Rental Sector

B.1.47 Similar conclusions can be draw for PRS accommodation, for the following reasons:

- an estimated demand of 750 bed spaces is unlikely to have any significant impact on an overall market of more than 50,000 bed spaces;
- the scale of demand falls well below the estimate of available capacity, even when that estimate is drawn from a series of conservative assumptions; and
- the demand on the PRS sector in the peak construction year of 750 bed spaces can be seen as small compared to the annual "churn" of approximately 10,000 bed spaces (20% of 50,000). In other words, this is a dynamic sector which sees seasonal and other workers entering, moving and leaving the sector on a regular, short-term basis in response to seasonal employment and other factors.

B.1.48 The evidence suggests, therefore, that it is unlikely that the influx of NHB workers, which would build up to a peak over a 4 or 5 year period, would have adverse impacts on the supply of either tourist or PRS accommodation within the local area.

B.1.49 In any event, EDF Energy has proposed a number of measures to ensure the absence of adverse impacts and to mitigate any impacts that do arise. These measures are detailed in the **Accommodation Strategy** but may be summarised as follows:

- the establishment of an Accommodation Office which would provide a service both to local accommodation providers but also to incoming HPC workers, matching their respective requirements;
- monitoring the home location of HPC workers and providing liaison and other facilities through the Accommodation Office to identify any adverse impacts that may arise;
- a flexible bus strategy which will allow routes to be varied and additional buses that run directly to the site to be provided. This could be used to make areas that have spare accommodation more attractive to workers. This would then reduce pressure on areas that have attracted large numbers of workers and where there may be pressure on accommodation capacity;
- applying an Accommodation Management Strategy to direct incoming HPC workers away from any areas of identified housing stress;
- a commitment to a Housing Fund of £5 million to be spent on a range of specified measures, each of which would stimulate supply in the private rented stock or provide financial assistance to local households seeking PRS accommodation; and
- committing to additional mitigation in the event that monitoring identified clustering of incoming workers beyond the capacity of local settlements.

B.1.50 Details of these mitigation measures are set out in the **Accommodation Strategy** and are discussed further in Section 9 of this Planning Statement, which considers necessary Section 106 obligations and requirements. As a package of measures, however, the **Accommodation Strategy** would, if implemented, ensure that there would be no adverse impact on the housing sector, whilst the accommodation proposals overall provide significant benefit for the owner occupied, tourist and latent accommodation sectors, as well as stimulating supply in the private rented, tourist and owner-occupied sectors and providing financial assistance for local households suffering hardship.

B.1.51 The proposals to construct three workers campuses also raise site specific planning issues but these are discussed in relation to specific sites in Section 8 of this Planning Statement.

B.1.52 Based on the above analysis, and the more detailed analysis set out in the Socio-Economic chapters of the Environmental Statement and the **Accommodation Strategy**, it can be confidently concluded that the HPC project would not generate adverse impacts on the local housing market.

iv. Leisure and Recreation

B.1.53 The influx of new workers into the area could generate additional demand for leisure facilities. In addition, the construction and operations of the associated development sites will impact on some existing facilities. In particular:

- The Bridgwater C campus would displace a rugby club training pitch;
- The development of Bridgwater A would result in the loss of the former Innovia playing field and social club;
- Enhanced wharf facilities at Combwich would disrupt facilities used by the local sailing club.

B.1.54 It is necessary to assess and to mitigate these impacts. Before assessing the details, however, it is relevant to note two important considerations, as follows:

- the DCO application proposals include leisure facilities. In particular, the description of the associated development proposals at Section 4.6 of this Planning Statement records the inclusion of sports pitches and changing facilities at Bridgwater A, similar facilities at the HPC development site accommodation campus and a sports pitch at Bridgwater C. Whilst these facilities are also to be made available to the public, they will make a significant contribution to meeting the leisure needs of construction workers; and
- the majority of indoor leisure facilities in West Somerset and Sedgemoor charge for entry, so that demand from HPC workers will help contribute to the viability and running of those facilities.

B.1.55 The potential for adverse impacts is directly addressed in the Socio-Economic Chapters of the **Environmental Statement**. The approach is founded upon a clear evidence base and Technical Note 5; “Leisure Audit and Estimated Demand” sets out the existing provision of sports facilities in Sedgemoor, West Somerset and Taunton and estimates the incremental demand that would be generated by HPC workers. The Technical Note uses the “Sport England Facilities Calculator” to identify the likely demand for provision. The assessment demonstrates that demand for sports facilities is very modest and is likely to be able to be met from existing provision and the campus proposals. The exception to this is where there is already a significant deficiency in sports provision, for example swimming pools, although the increased demand for these facilities is assessed to be small. Taking account of the facilities directly provided at the associated development sites, the assessment concludes that the level of non-home based workforce would need to more than double to generate a net impact on provision greater than that already being provided through the campus facilities. Impacts on other sports provision are likely to remain negligible in any plausible scenario (**Socio-Economic Assessment** para 9.1.506).

B.1.56 Consideration has, however, been given to the impact of the associated developments on existing leisure facilities. EDF Energy will be obliged to replace the rugby training ground as part of its land agreement for the Bridgwater C campus, so that the principal physical impacts of the associated developments relate to the loss of the facilities at Bridgwater A and to any disturbance to the activities of the sailing club at Combwich. Section 8 of this Planning Statement considers site specific impacts directly with the benefit of Appendices 7-14 which review each site in more detail. That analysis shows, for instance, that full provision is being made in the design of the Combwich Wharf facilities to replace and enhance the facilities available to the sailing club.

B.1.57 At Bridgwater A, as Appendix 7 explains, planning permission has been granted which accepts the principle of the loss of the social club and playing field at the former Innovia site, as part of the North East Bridgwater Masterplan consent. Nevertheless, as part of the work undertaken in the preparation of the Site Preparation Section 106 Agreement, estimates were made based on the SDC Infrastructure Delivery Strategy of the cost of reproviding in full the sports pitch and the social club. The estimated cost of reprovision was £435,000. Estimates were also made of the total cost of meeting the leisure needs of the HPC construction workforce and mitigating in advance all of the leisure impacts of the HPC project. Through the Site Preparation Section 106, therefore, a substantial commitment is proposed to safeguard against the risk of impact, with the following characteristics:-

- £250,000 towards the provision of new or improved sports and leisure facilities within West Somerset;
- £500,000 towards providing new or improved sports and leisure facilities within the parish of Stogursey;
- £250,000 as a contribution towards the new swimming pool under construction at Chilton Trinity Technical College in Bridgwater;
- £500,000 to provide new or improved sports and leisure facilities within Bridgwater; and
- £500,000 to provide new or improved sports and leisure facilities within Cannington.

B.1.58 The purpose of this commitment was to provide advanced mitigation for the impacts of the DCO project. Based on the analysis set out in the **Socio-Economic Assessment**, it is apparent that these contributions fully mitigate impacts that might arise from the construction workforce, even at the peak of construction activity.

B.1.59 The commitment to provide £500,000 towards sports facilities in Bridgwater meets the calculated cost of reproviding the sports club and playing field that would be lost as a consequence of the Bridgwater A accommodation campus development. This commitment was deliberately made as part of the Site Preparation Section 106 Agreement in order to put in place early mitigation so that the development of the campus could proceed as soon as the DCO is granted. EDF Energy has been working with Somerset Leisure and SDC to target the most effective use of the commitment and the current expectation is that the funds would be applied to enhance and extend leisure facilities in East Bridgwater.

B.1.60 Potential recreation and amenity impacts are also addressed in detail in the Environmental Statement. In particular, the assessment identifies the commitment made as part of the Site Preparation Section 106 Agreement to fund substantial enhancements to the network of Public Rights of Way in the vicinity of the main development site and the coastal areas, principally to the west. These plans have been developed and agreed with Somerset County Council. As part of the Heads of Terms for the Section 106 Agreement for the DCO (see Section 9), EDF Energy intends to extend these commitments to include further enhancements, particularly to the Parrett Trail and to the coastal footpath network to the east of Hinkley Point. The net effect of these commitments would be an enhancement of the rights of way network. The commitments made through the Section 106 Agreements will leave a legacy of enhanced facilities.

v. Public Services and Community Cohesion

B.1.61 EDF Energy has been consulting with key public service providers through a formally established group, the Emergency Services and Local Authorities Group, since September 2010 in order to increase its depth of understanding of the current roles of the providers and potential community safety issues arising from the construction and subsequent operation of Hinkley Point C. Meetings have been held on a monthly basis and attended by the local authorities (SCC, WSC and SDC), Avon and Somerset Constabulary, Devon and Somerset Fire and Rescue Service, South Western Ambulance Service Trust and Her Majesty's Coast Guard.

B.1.62 In addition to monthly meetings attended by all stakeholders, regular bilateral meetings have been held in order to progress points of detail. Service relationship protocols have been discussed with providers and workshops have been held with the Group at key stages in order to establish potential impacts, to review construction proposals, to assess the approach to traffic incident management and to establish governance arrangements for the group through the construction period.

B.1.63 The output for the purposes of the DCO application is a **Community Safety Management Plan** appended to which are:

- a worker code of conduct; and
- the Outline Contingency Response Arrangements (OCRA).

B.1.64 In addition, the principles of a **Traffic Incident Management Plan** have been agreed and these are reported in the **Transport Assessment**.

B.1.65 It is proposed that the group will continue to meet in order to work together to deliver key objectives of the above strategies, to monitor impacts on community safety arising as a consequence of the HPC project and to make recommendations for action. The **Heads of Terms for the Section 106 Agreement** set out a framework of funding in order to facilitate the ongoing working of the Group. Through this constructive, comprehensive engagement, EDF Energy has worked successfully with the service providers in order to ensure that the impacts arising from the HPC project on key local services can be fully addressed.

B.1.66 In this respect, EDF Energy recognises that the influx of non home based workers, along with the scale of activity which the HPC project will generate will result in change in the local economy and local communities. The measures described above and other commitments described below (and set out in **the Heads of Terms for the Section 106 Agreement**) combine to ensure that any adverse impacts on community cohesion will be appropriately addressed. In particular:

- community safety issues have been comprehensively addressed through the measures outlined above, including the funding of a Community Safety Beat Team within the police service, as well as additional funding for community safety resources in the three local authorities;
- incident management and contingent response arrangements are in place to address unexpected events;
- investment by EDF Energy in comprehensive education, training and local recruitment initiatives in order to maximise the opportunity for local people to achieve employment and training and to become part of the HPC project;
- EDF Energy has worked hard to ensure that the project does not marginalise sectors of the local communities – in particular, investment is proposed in community outreach and youth worker programmes to ensure that traditionally "hard to reach" groups can be given every opportunity to benefit from the project;
- the worker Code of Conduct will be rigorously enforced if necessary and EDF Energy will have additional oversight of worker behaviour through its **Accommodation Management Strategy** and through the provision and management of accommodation campuses; and
- worker induction will include extensive information about local services in order to enable workers to engage with the local community.

B.1.67 The HPC project, therefore, is fully mitigating its potential impacts on sectors of the local community including housing, leisure, recreation and other services. In fact, through the extensive investment in local services and facilities, together particularly with the education, employment and training initiatives set out above, the HPC project is expected to provide a major boost to the local economy and a major opportunity for local communities.

vi. Health Effects

B.1.68 NPS EN-1 and EN-6 provide clear guidance to the IPC on the approach that is appropriate to the potential health impacts of an NSIP. In particular, NPS EN-1 is careful to ensure that those matters which are subject to separate regulation are appropriately considered through those other regimes (see earlier paragraph 6.2.8 and Appendix 6). This includes issues to do with nuclear safety, as well as Health & Safety, so that para 4.13.5 advises:

> *"… so that it is unlikely that health concerns will either constitute a reason to refuse consents or require specific mitigation under the Planning Act 2008."*

B.1.69 The same paragraph goes on to explain that the IPC will want to take account of health concerns when setting requirements relating to a range of impacts, such as noise. Health does not appear, however, in Section 5 of NPS EN-1 which sets out the Generic Impacts for the IPC to consider, although that list is not exhaustive.

B.1.70 NPS EN-6 is consistent with this approach. In relation to radioactive waste management, for instance, paragraph 2.11.6 states that the IPC should act on the basis that the relevant licensing and permitting regimes will be properly applied and enforced.

B.1.71 Human health and well-being, however, is a heading in Part 3 of NPS EN-6, ie matters for the IPC to consider when assessing potential impacts and siting considerations of new nuclear power stations. Human health and well-being, therefore, is a "Flag for Local Consideration". The guidance provided, however, puts that issue into context in the following way:

- the operation of a new nuclear power station is unlikely to be associated with significant noise, vibration or air quality impacts (although there may be local impacts from transport and associated activities during construction). With appropriate mitigation, the subsequent effect of these potential impacts on human health is unlikely to be significant (para 3.12.3);
- the process of construction, operation and decommissioning, however, could affect healthcare provision (para 3.12.5); and
- the Nuclear AoS identified that there could be positive effects for health and well-being resulting from the positive socio-economic benefits of new nuclear power stations (para 3.12.6) and the IPC is asked to consider the positive effect of employment and other socio-economic impacts on human health and well-being (para 3.12.8).

B.1.72 The NPS, therefore, identifies the potential need for mitigation, particularly during construction and the need to consider the possible effect on healthcare provision. Other matters particularly the risk of adverse effects resulting from exposure to radiation are not matters for the IPC, who are asked to act on the basis that such risks will be adequately mitigated through other regimes (para 3.12.11).

B.1.73 Further context for Hinkley Point C is provided by the Site Assessment set out at Annex C of NPS EN-6, which confirms that the development at Hinkley Point is appraised as having positive economic effects, including positive effects on community viability (para C.5.85). The Assessment is aware that the presence of a nuclear power station may lead to increased stress levels in certain individuals but advises:

> *"C.5.99….Overall, the Appraisal of Sustainability finds that likely enhancement in employment, community wealth, housing stock and other associated neighbourhood infrastructure should improve community well-being and health generally."*

B.1.74 Against that background, EDF Energy has sought to engage with the community and relevant stakeholders and it has taken a number of measures which are brought together in the **Health Impact Assessment** (the HIA). The HIA explains its own objective as follows:

> *"1.3.1 The primary aim of the HIA is to build on and complement the outputs of the Environmental Statement to further integrate health and well-being within the HPC project, identify and assess potential health outcomes*

and put forward recommendations to maximise health gains whilst minimising potential negative impacts".

B.1.75 It would not be appropriate in this Planning Statement to review in detail the terms of the HIA or of its associated **Health Action Plan** (HAP). Nevertheless, those documents demonstrate that EDF Energy has adopted a comprehensive approach to all relevant health related matters, including community well-being.

B.1.76 As with other topic areas, there has been extensive engagement with relevant stakeholders. This is related in Section 4 of the HIA, whilst Section 7 also identifies that a Health Task and Finish Group (HTFG) was formed in November 2010 to support the development and refinement of the HAP and to monitor its delivery. The HTFG includes representation from the local authorities but also from the principal health service providers, including the PCT and the South West Ambulance Trust. EDF Energy has funded the operation of that group and the Site Preparation Section 106 Agreement proposes a payment of £60,000 to the group to enable it to undertake its own studies to ensure readiness for the HPC project.

B.1.77 To address the health and well-being of its own workforce, EDF Energy is committed to a number of initiatives including:

B.1.78 the engagement of Duradiamond Healthcare as the provider of occupational healthcare services to the workforce during construction. Duradiamond provide extensive healthcare services to workers including:

- screening and preventative healthcare;
- regular health reviews;
- a programme of health promotion;
- the application of a Drug and Alcohol Policy (which includes testing but also confidential advice);
- on-site treatment for accidents or illness; and
- emergency response.

B.1.79 Not only does this provide a high level of healthcare service to HPC workers, it also significantly reduces pressure on local healthcare services;

- close working with the Ambulance Trust and an agreed funding formula to pay for any necessary ambulance and health services when workers have health issues which exceed the expertise of capacity of the on-site facilities; and
- funding to cover the NHS costs of referrals for both construction workers and their families and dependents.

B.1.80 This combination of measures fully addresses the NPS requirement to have regard to the impact of the workforce on local health services.

B.1.81 Potential health impacts on the community are more difficult to identify and address. As the HIA makes clear, EDF Energy's principal approach has been to design the HPC Project in order to limit its potential effects and then to comprehensively mitigate any residual effects which may, for instance, give rise to significant health or well-being impacts. Drawing on the **Environmental Statement**, this Planning Statement identifies in Section 7, 8 and 9 how strategies are in place to avoid, reduce or mitigate significant effects arising from transport, noise, air quality, visual impacts, community safety and other environmental effects..

B.1.82 If these overall strategies are successful, impacts will have been reduced as far as practical and outstanding health impacts may relate to less easily addressed matters such as the stress and anxiety that can be caused by an intervention in local community life on the scale of a project like Hinkley Point C. The HIA seeks to address these issues as far as practical, informed by extensive engagement and, for instance, by a Community Well-Being Survey undertaken in smaller settlements local to the main development site at Hinkley. To address those concerns it identifies a range of proposals including:

- **Communication and Openness:** is important in reducing unwarranted fears and in helping to integrate the project into the community. The HAP sets out proposals for newsletters, local forums and for the ready availability of monitoring information to be provided to the community.
- **Main Site Neighbourhood Support Scheme:** EDF Energy has consulted upon and published a neighbourhood support scheme that would apply in the hamlets close to the main development site, ie Burton, Shurton, Wick and Stolford. The scheme is conditional only on implementation of the HPC project and it would provide assistance with noise insulation for properties and a Property Price Support Scheme which would underwrite any loss in value of property which might arise from the HPC project. The scheme is a voluntary scheme and it has been received well by the local communities. It is not strictly a planning scheme because the anticipated noise measurements do not generate a necessity for mitigation and because property value is not strictly a planning consideration. Nevertheless, this initiative should be helpful in addressing some elements of local community concern.
- **Noise Insulation:** a scheme is proposed to provide noise insulation from construction traffic in Cannington and from activities at the wharf at Combwich as part of the **Heads of Terms for the Section 106 Agreement** for the DCO (see Section 9).
- **Maximising Local benefits:** consistently with EDF Energy's Vision for the HPC project, this Planning Statement has already identified a series of measures aimed directly at maximising local opportunity and benefit for residents and communities – particularly in relation to education, training, employment, housing and leisure facilities. The ability for local people to gain employment at Hinkley Point C or to benefit from training associated with the project will not only aid integration of the project into the community but also directly enhance the quality of life for local residents.

B.1.83 In addition, EDF Energy has proposed a Community Impact Fund. The fund is explained in more detail in Section 9 but its principal purpose is to mitigate residual impacts on the quality of life caused by the HPC project. EDF Energy's vision for the Fund is that it would be spent in the community by the community on projects which the community considers would maintain and enhance the quality of life locally.

B.1.84 In combination with the full range of requirements and obligations proposed as part of the DCO application, in addition to those agreed as part of the Site Preparation

Section 106 Agreement, these measures responsibly address those health impacts that have been identified as arising from the HPC project.

b) Transport

B.1.85 The transport effects of the HPC project during its construction (including the noise effects of traffic) are amongst the more significant and contentious effects of the project as a whole. They are the subject of detailed consideration in the **Transport Assessment** and in the Transport and Noise chapters of the **Environmental Statement**. It is not intended to review them in detail in the Planning Statement.

B.1.86 Nevertheless, it is important to identify the scale of adverse effects in order that these can be weighed in the overall planning balance within the context of national policy.

B.1.87 NPS EN-1 and EN-6 provide short but helpful guidance on the approach to be taken to the transport effects of a NSIP. NPS EN-1 explains at para 5.1.2 that it is for the NPSs to define the level of weight that should be given to any impacts of a relevant project.

B.1.88 The most significant elements of the NPS EN-1 guidance are as follows:

- a recognition that a new energy NSIP may give rise to substantial impacts on the surrounding transport infrastructure including during the construction phase of the development (para 5.13.6);
- mitigation is expected to "*reduce the impact on the transport infrastructure to acceptable levels*" (para 5.13.6); and
- provided that the applicant is willing to enter into planning obligations or requirements to mitigate transport impacts (to acceptable levels), development consent should not be withheld and "*appropriately limited weight should be applied to residual effects on the surrounding transport infrastructure*." (para 5.13.7).

B.1.89 It follows that there is no obligation to mitigate all transport effects and that it is always likely that there will be some residual transport effects arising from large infrastructure projects. The relevant question, therefore, is to address how transport effects might be reduced to "*acceptable levels*" and what those acceptable levels might be.

B.1.90 Specifically in relation to nuclear power generation, NPS EN-6 provides as a Flag for local consideration the question of "*impact on significant infrastructure and resources*" (para 3.15). Those resources are identified as including motorways and major highways and paragraph 3.15.2 requires that applications should demonstrate that the proposed development would not have an unacceptable adverse impact on such infrastructure. The following paragraph (3.15.3) confirms that the Nuclear AoS identified that there may be adverse effects during the construction and decommissioning phases on regional transport networks which may already be under stress, particularly where there are clusters of potential sites for new nuclear power stations. This Flag provides some helpful context in determining the scale of what adverse effects may need to be in order to carry significant weight in IPC decision making on an application for a nuclear power station.

B.1.91 Whilst some residual impacts, therefore, may be acceptable, particularly on the local highway network, the NPSs are clear that promoters should prepare a Transport Assessment and a Travel Plan and that transport strategies should seek to reduce and mitigate impact. In particular, the following suggestions are relevant:

- where mitigation is needed, possible demand management measures must be considered if feasible and operationally reasonable before considering requirements for the provision of new inland transport infrastructure (para 5.13.8);
- the IPC should consider the cost effectiveness of demand management measures compared to new transport infrastructure as well as the aim to secure more sustainable patterns of transport (para 5.13.9);
- water borne or rail transport is preferred over road transport at all stages, where cost effective (para 5.13.10);
- the IPC should consider requirements to control the number of HGV vehicle movements on particular routes and at particular times and make sufficient provision for HGV parking to avoid overspill parking on public roads or prolonged queuing (para 5.13.11); and
- satisfactory arrangements need to be made for reasonably foreseeable abnormal disruption (para 5.13.11).

B.1.92 These helpful elements of advice correlate closely with the Transport Strategy which EDF Energy has adopted for the HPC project and which was outlined in Section 4 of this Planning Statement. In particular:

- EDF Energy proposes a bus based strategy for the transport of workers, and this is enabled by the use of four park and ride car parks, as well as by direct buses from principal settlements;
- two freight management sites are proposed in order to limit overspill HGV parking or queuing and to control HGV movements so that they occur in a steady flow and can be reduced during peak traffic periods;
- defined traffic routes are identified and monitoring arrangements proposed to enforce their use and this is complemented by proposed requirements which would restrict HGV vehicle movements on key routes and by shift patterns which are also designed to avoid peak periods;
- substantial investment is proposed in the new temporary jetty and the improvements to Combwich Wharf in order to maximise the potential to bring materials by sea – directly in accord with the NPS guidance;
- highway improvements at important junctions, noise mitigation in Cannington and public realm enhancements on transport routes in Cannington and Bridgwater are all proposed in order to mitigate the impacts of construction traffic;
- the Cannington Bypass is proposed in recognition of the fact that Cannington would see the biggest change in traffic conditions, with all construction traffic otherwise routed through the village; but
- a Bridgwater Bypass is not proposed because the transport assessment demonstrates that the demand management measures and highway improvements proposed bring traffic impacts within acceptable levels in

Bridgwater and that the construction of a ByPpass would not be cost effective nor would it be consistent with the sustainability objectives of the NPS.

B.1.93 The HPC Transport Strategy, therefore, is considered to be directly consistent with the advice and requirements of the NPSs. Nevertheless, there are residual transport impacts and related planning issues to take into account.

B.1.94 The detail of the Transport Assessment is too complex to report within the Planning Statement but there are some high level outcomes that can usefully be recorded. The detailed transport analysis is contained within the Transport Assessment whilst the Transport Volume of the **Environmental Statement** assesses the significance of transport impacts against five principal criteria:-

- severance;
- pedestrian delay;
- pedestrian amenity;
- driver delay; and
- accidents and safety.

B.1.95 Impacts are assessed at 2013, 2016 and 2021, i.e. at the beginning, middle and the end of the construction period. The assessment uses a Paramics Transport Model which has been validated and agreed with the Highway Authorities.

B.1.96 The assessment at each year compares the 'without' and 'with' development scenarios and takes account of a number of highway improvement works which are proposed by EDF Energy across the network to address anticipated impacts. At 2016 and 2021 the model shows the net effect of the HPC traffic with the proposed highway improvements in place. At 2013, not all of the highway improvements would be in place and not all of the associated development sites would be available to use. The 2013 assessment, therefore, shows an "*early years*" assessment, which is different in some important respects from the later assessments.

B.1.97 As part of the draft DCO application for Hinkley Point C, a package of highway improvements is proposed for the urban areas of Bridgwater and Cannington and elsewhere on the local highway network to provide mitigation for the transportation impacts of the HPC Project. These improvements are proposed at points on the highway network where they are considered necessary for highway safety and/or highway capacity reasons. The off-site highway works are described in detail in the Transport Assessment and comprise:

- A38 Bristol Road/The Drove Junction – increase in width of highway to improve operation of the junction;
- A39 Broadway/A38 Taunton Road Junction – changes to signal arrangements, minor carriageway realignment to improve operation of the junction;
- A38 Bristol Road/Wylds Road Junction – increase in width of carriageway and right turn lane to assist right turns and reduce queuing;
- Wylds Road/The Drove Junction - provision of a left-turn slip road from Western Way into Wylds Road to improve operation of the junction;

- A39 New Road/B3339 Sandford Hill Roundabout – new roundabout to improve safety of junction;
- M5 Junction 23 Roundabout – changes to signal arrangements and minor carriageway widening on slip road to improve operation of roundabout;
- Washford Cross Roundabout – new roundabout to improve safety of junction;
- Claylands Corner Junction – minor carriageway widening to improve operation of the junction;
- C182 Farringdon Hill Lane, Horse Crossing – provision of horse crossing to improve safety for horses and riders;
- Cannington Traffic Calming Measures – traffic management measures;
- Huntworth Roundabout – increase in width of eastern arm of roundabout to reduce queuing; and
- Bath Road – minor works within the highway to facilitate access to Bridgwater A.

i. Effects in Bridgwater

B.1.98 One of the important preliminary points to note is that the model has taken the maximum or peak traffic flows anticipated for the project and, therefore, represents a worst case assessment. As the Transport Assessment explains, limits are proposed on quarterly movements but there is flexibility for these to be exceeded on individual days, so long as the overall quarterly average is respected. It is these higher daily limits that have been used in the assessment. Timing requirements are also proposed to ensure that the majority of HGV traffic does not coincide with peak periods. Against this background, there are some important headline outputs from the assessment, including:

- Overall, the highway improvements package increases capacity in Bridgwater by more than the scale of the additional traffic (Transport Chapter of the ES Section 10);
- As a result, overall journey speeds are maintained. At 2016, for instance, the output shows that the average vehicle speed across the model network of 29.1 miles per hour changes only to 29.0 miles per hour even when allowance is made for the HPC construction traffic and other growth on the transport network; and
- Consequently, the impact on journey times across the network is also broadly neutral.

B.1.99 These headline outputs, of course, are an inadequate summary of detailed impacts which occur across the network. In principle, however, they suggest that the combination of the Transport Strategy and the highway improvement works is sufficient to broadly maintain the performance of the highway network during the construction period.

B.1.100 It also follows from this high level review that the local highway network will be left significantly improved after the construction of Hinkley Point C, when traffic levels will return to a lower level but the highway improvements will remain in place. The HPC project, therefore, creates a legacy of highway improvements across the network in exchange for some short-term impacts.

B.1.101 In terms of the matters assessed within the **Environmental Statement** at 2016, the Transport Volume reports some moderate adverse severance impacts on some routes through Bridgwater and corresponding impacts on pedestrian amenity. For Bridgwater routes, however, it identifies that all of the routes in question are A roads which are expected to take HGV traffic and that, in general, these roads only have a modest number of residential properties fronting on to them. The commitment to specific traffic routes prevents adverse impacts arising elsewhere. In terms of Accidents and Safety, the assessment identifies that the planned highway improvements address principal issues, so that the overall assessment under this heading for 2016 is "*minor adverse*".

B.1.102 These are not a scale of adverse effects that could justify rejection of the DCO application.

B.1.103 The NPSs provide guidance also on the consideration of noise, although the majority of the guidance is concerned with long term operational noise from NSIPs. Paragraph 5.11.5 of NPS EN-1 does also expect, however, that the noise impact of activities associated with development, such as increased road and rail traffic movements should be considered.

B.1.104 In relation to noise from road traffic, the impact assessment during construction has been conducted for the years of 2013 and 2016. These are the years that have been assessed in the transport assessment and represent the peak periods of traffic generation during HPC construction. The 2013 assessment includes the peak period of HGV movements and the 2016 assessment includes the peak period in terms of workforce numbers.

B.1.105 The principal potential adverse impacts which have been considered essentially fall into two categories. The first of these is daytime noise impacts which arise principally from the HGV movements to and from the HPC Development Site. These movements will be limited to the two authorised HGV Routes which are the principal roads through Bridgwater. HGV movements on these routes will be restricted to between the hours of 7am and 10pm. Robust assumptions have been made on HGV movements in the transport modelling which has been used for the noise impact assessment.

B.1.106 The second area of impacts is noise which arises early in the morning or late in the evening from bus movements to bring the HPC construction workforce to and from the HPC Development site. These movements will not occur through the night but will align with the beginning of the first construction shift and the end of the second construction shift and will be limited to a window of approximately 1.5-2 hours. As with HGV movements, the modelling of bus movements has been made on robust assumptions which assume that very regular timetables operate on all direct, campus and park & ride bus routes associated with the beginning and end of each construction shift. These timetables are not fixed at this stage and will be finalised once a bus operator has been appointed to provide the bus services. In practice bus provision and timetables will be regularly adjusted to match the changing patterns of demand and the actual number of buses on many routes is likely to be significantly less than has been modelled at many points in the construction programme. However, at this stage and for the purpose of providing a very robust assessment of transport and noise impacts, fixed timetables on all routes have been used in the modelling.

B.1.107 Noise impacts arising from daytime HGV movements in Bridgwater are assessed as minor adverse in either 2013 or 2016. Moderate or major adverse impacts have been assessed in Bridgwater for the shorter periods of time associated with early morning and late evening bus movements which, have, as noted above, been modelled on a robust basis. These impacts are also limited to the two existing A roads which are recognised as the main corridors for traffic through Bridgwater. Nevertheless, there are noise impacts for the affected properties.

B.1.108 It is not possible to undertake a construction project of the scale of Hinkley Point C without some adverse impacts arsing somewhere on the network from construction vehicles. In the case of Hinkley Point C the potential impacts have been reduced by the sea based strategy for concrete making materials, other construction materials and AILs and by the use of the Freight Management sites, restrictions on hours of operation and by confining the impact to the most suitable routes. The scale of residual impacts is modest in the context of the scale of the construction project.

ii. Effects in Cannington

B.1.109 In Cannington at 2016, the assessment assumes that the Cannington Western By-Pass will be in place. The bypass would result in a reduction in traffic flows relative to existing levels. The position in 2013, however, is different and the Transport Volume identifies that daily vehicle flows on Cannington High Street will increase by 1,391 vehicles or 64% of the existing flow before the by-pass is in place – which is expected to be open to traffic in Q4 2014. For approximately a 15 month period, therefore, Cannington would experience significantly increased flows through the village whilst the bypass is being constructed. In these circumstances, the Transport Chapters of the **Environmental Statement** Volume identify substantial adverse effects on severance and pedestrian amenity, although there are no significant highway capacity issues that would generate driver delay. In addition, the noise chapters identify major adverse effects on the C182 (Rodway) and High Street in Cannington. This temporary, early years impact in Cannington is one of the most significant impacts of the HPC project.

B.1.110 The scale of adverse road traffic noise impacts is greatest in Cannington prior to the construction of the Cannington bypass. Properties adjacent to the road in Cannington on the HGV route to Hinkley Point will experience both daytime noise impacts from HGV movements which are assessed as major adverse and early morning/late evening noise impacts from bus movements which are also assessed as major adverse. The absolute change in noise levels arising from HPC related traffic is also significantly higher in Cannington prior to the construction of the bypass than would be the case in Bridgwater.

B.1.111 The principle of HPC construction traffic routing through Cannington village in the absence of a bypass has been accepted by the local planning and highway authorities through the grant of planning permission for the enabling works and the resolution to approve the site preparation works. The enabling works consent, the construction of the jetty and the site preparation works would all generate construction and worker traffic through Cannington and no by-pass has been said by the planning or highway authorities to be required as a part of any of those planning consents or resolutions. Instead, the draft planning consent for site preparation works proposes a limit on HGV vehicle movements through Cannington and the

WSC committee resolution to approve the application was based on the following approach:

- vehicle movements are to be limited to those assessed in the Site Preparation Transport Assessment. HGV movements are relatively small in the first quarter, (ie 28 movements per day) but they rise over the fifteen month construction period reaching over 200 movements per day for quarters 2-5, peaking at 290 movements per day in quarter 3;
- HGV movements would not be permitted between 18:00-07:00;
- maximum flows in the highway peak hour will be restricted to 24 movements and restricted to 30 movements per hour at other times;
- a series of traffic calming and safety improvements are were proposed in Cannington including a Parking Traffic Regulation Order and minor changes to Memorial Junction (the junction of High Street and Rodway), as well as enhanced pedestrian crossing facilities. In addition, safety improvements and speed restrictions are proposed on the C182 between Cannington and Hinkley Point; and
- approximately £200,000 is to be committed to public realm heritage improvements in Cannington to offset the impact on the Conservation Area of the increased traffic levels.

B.1.112 Against this background, a requirement is proposed within the draft DCO application which would limit average daily HGV movements over a quarter to 250 each way, i.e. 500 movements. Flexibility is required, however, to cater for daily variations up to 750 movements per day. HGV operating hours would be extended to 22:00 but, again, there would be no movements after that time and until 07:00 in the morning.

B.1.113 Upon approval of the DCO, EDF Energy intends to let the principal civils works contracts and to commence construction as quickly as possible. A continuation of the site preparation HGV limits would severely inhibit the construction of the NSIP. Consequently, EDF Energy has considered the acceptability of the early years flows and what further mitigation could be proposed to mitigate the short-term impacts on Cannington during this early construction period. The **Heads of Terms for the Section 106 Agreement** propose the introduction of a noise mitigation scheme, with noise insulation being offered to properties along High Street and Rodway. Properties which take up the noise insulation scheme and install double or secondary glazing would be provided with the lasting benefit in exchange for a short-term impact. That impact arises from traffic but it is relevant to identify that there is no traffic capacity issues through Cannington – rather, the issues relate to noise and amenity.

B.1.114 Cannington would be a long term beneficiary of the bypass which would relieve it of construction, operational and outage traffic after Q4 2014. The Transport Assessment shows that there would be significant reductions in traffic flows through Cannington once the bypass is open. The village would also benefit from other investments set out in the **Heads of Terms of the Section 106 Agreement** including significantly improved leisure facilities, improvements to the village school, public realm, parking and pedestrian crossing enhancements. None of these directly mitigate the short-term impact from elevated levels of construction traffic but they do demonstrate that EDF Energy has sought to comprehensively address the impact of the project on the village.

B.1.115 Against this background, the short-term impact on Cannington is not considered to be so adverse that restrictions should be imposed which would severely inhibit the construction of the power station, particularly given the urgency with which the need is expressed in national policy.

B.1.116 Whilst the draft DCO application does propose a Cannington Bypass, it does not propose a bypass for Bridgwater. The need or otherwise for a Bridgwater Bypass has been a regular theme arising from engagement and consultation and it is the policy of SCC, WSC and SDC that EDF Energy should assess the need for a Bridgwater Bypass as part of the Hinkley Point C DCO application. In order to explain EDF Energy's position in relation to a Bridgwater Bypass in more detail, the **Bridgwater Bypass Study** has been prepared as part of the DCO application documents. EDF Energy also published the *HPC Bypass Report* in July 2010 as part of its Stage 2 consultation. That Bypass Report concluded that:-

- a Bridgwater Northern Bypass would be within the floodplain and pass close to sensitive environmental areas;
- it would take four years to build and waiting for the bypass would substantially delay the operation and the carbon-saving benefits of the HPC power station; and
- a Bridgwater Bypass is not necessary because the transport effects of the HPC project through Bridgwater can be accommodated with improvements to the existing highway network.

B.1.117 Some parties making representations on the emerging HPC proposals have drawn a parallel with the 1988-1989 Hinkley Point C planning inquiry where the promoter (the CEGB) proposed funding for a Bridgwater Bypass. The representations suggest that this establishes a principle that a Hinkley Point C Nuclear Power Station should provide a bypass. As set out in Section 3, a number of matters have moved on significantly since that time. In particular:

- the CEGB proposals did not include a temporary jetty for the delivery of bulk aggregate and other construction materials;
- The CEGB proposals did not include park and ride sites or a bus based strategy for employees and visitors – instead, a car based strategy was proposed with 1,400 on site car parking spaces;
- the CEGB proposal did not include investment in a Delivery Management System or in freight management sites, such as those proposed by EDF Energy at junctions 23 and 24 which would have the effect of holding back HGV traffic so that it principally serves the site outside peak hours; and
- National policy has moved on significantly since the late 1980s/early 1990s to the extent that policy now emphasises a priority to manage traffic, to achieve modal shift and to optimise the use of existing infrastructure: new road building is discouraged as a mitigation measure.

B.1.118 The **Bridgwater Bypass Study** confirms this analysis. It also reviews the policy background to the need for a Bridgwater Bypass. That review identifies that a Bypass for Bridgwater has never been proposed within a statutory planning policy document and that even the more recent informal planning policy documents such as the draft Hinkley SPD or the County Council's Future Transport Plan do not set out a requirement for the bypass – rather, they set out a requirement for the need for the bypass to be assessed by EDF Energy. The review also identifies that the local planning and highway authorities have permitted the substantial growth of Bridgwater and have planned considerable continuing growth through the Core Strategy, without any expressed requirement for a bypass. Similarly, major planning applications such as the North East Bridgwater Masterplan, which generate more peak hour traffic than the HPC project have been consented without a requirement for a Bridgwater bypass.

B.1.119 The principal relevant evidence, of course, is the **Transport Assessment** submitted as part of the DCO application. As explained above, the **Transport Assessment** confirms that the temporary construction transport impact of the project can be accommodated within the existing highway network thanks to the operation of the Hinkley Transport Strategy which reduces the need to travel, achieves modal shift away from the use of the car and controls lorry movements outside peak periods. That approach is directly consistent with the advice provided in NPS EN-1, as follows:-

> *"5.13.18 Where mitigation is needed, possible demand management measures must be considered and if feasible and operationally reasonable, required, before considering requirements for the provision of new inland transport infrastructure to deal with remaining transport impacts."*

B.1.120 In conclusion, EDF Energy has adopted an approach to managing the temporary impacts of construction traffic which is directly consistent with national policy. As a result, the **Transport Assessment** demonstrates that the principal adverse impacts can be mitigated and that the residual impacts fall within acceptable levels. Short term noise impacts do arise, particularly when assessed on a worst case basis, but short term impacts on principal routes for limited hours of the day cannot justify the provision of a bypass.

B.1.121 Operational traffic is also assessed but, inevitably, is much less than the construction traffic. The analysis demonstrates that the transport interventions at the park and ride and freight management sites can be removed at the end of the construction period, whilst the transport effects of operational traffic would fall within acceptable levels. Overall, the highway network would be improved through the highway works proposed as part of the DCO application, including the Cannington Bypass.

c) Conclusions in Relation to Project-Wide Effects

B.1.122 This section of the Planning Statement has demonstrated that the HPC project would not have impacts on the local or the wider area which are of such a scale as to warrant refusal of the DCO application. Mitigation and controls, however, do need to be in place and these are explained in Section 9 of the Planning Statement.

B.2 Planning Analysis: Site Specific Considerations

B.2.1 The HPC Project is a single NSIP, spread over 9 principal sites. In addition to the main development site at Hinkley Point, there are 8 principal off site developments together with a number of smaller off-site highway improvement works. The principle of seeking development consent in a single application is central to the regime established for nationally important infrastructure under the Planning Act 2008. As the Planning White Paper, *Planning for a Sustainable Future* (May 2007) which preceded the 2008 Act explained, a core principle of the White Paper was that the planning system should be "*streamlined, efficient and predictable"* para (1.37). Accordingly, one of the key principles in relation to NSIPs was to streamline the procedures to create a single application process. As paragraph 5.18 of the White Paper explained, in order to ensure that the IPC is able to grant the authorisations necessary to construct these projects it is proposed to:

> *"rationalise the different development consent regimes and create, as far as possible, a unified, single consent regime with a harmonised set of requirements and procedures."*

B.2.2 NPS EN-1 at paragraph 1.4.3 makes clear that it is the NPSs which will be the primary basis for IPC decision-making on associated development (as well as for the NSIP itself). This Planning Statement has sought to explain the distinction in legal terms between the "generating station" and its "associated development" (see earlier paragraph 2.1.28) but it is apparent that the HPC project should be considered as a whole and it is clear from the NPS that the same planning principles apply to each element of the project.

B.2.3 The weight to be attached to local policy, for instance, is the same for the associated development as it is for the main development site.

B.2.4 Whilst the draft Hinkley SPD draws attention to the relative lack of guidance with the NSIPs for associate development sites (draft Hinkley SPD para 2.7), there is no expectation or requirement in the NPS for this lack of detail to be filled by local policy. The associated development is part of the NSIP and the delivery of nationally important infrastructure could potentially be put at risk if its different elements were subject to different policy regimes or if local policy sought to duplicate, confuse or compete with the primary national policy guidance.

B.2.5 The approach taken to policy is explained in Section 6 of this Planning Statement which recognises that the principal test to be applied to the DCO application is that set by Section 104 (7) of the Planning Act 2008, ie whether the IPC "*is satisfied that the adverse impact of the proposed development, would outweigh its benefits."* It is important to identify, therefore, whether there are adverse impacts of the proposed development, rather than whether there may be any conflicts arising with local policy either from the project as a whole or from the development of individual sites. Local policy may be helpful, however, in identifying where adverse effects might arise.

B.2.6 Against that background, **Appendices 7-14** review the planning issues arising from the proposed development of the individual sites, which collectively make up the HPC project. That analysis is not repeated in this section, nor does it seek to replicate the very extensive information available on the individual sites provided in the **Environmental Statement**, the **Alternative Sites Assessment** (Appendix 3) or the individual **Design and Access Statement** documents which relate to the individual sites. Instead, this section seeks to draw out the principal issues that arise from the Appendices in order that they may help to inform the overall planning balance. This section deals first with associated development sites and then with the main development site.

a) Associated Development Sites

i. Issues of Principle

B.2.7 Section 115 (1) of the Planning Act 2008 provides that development consent may be granted for development for which development consent is required or for associated development. Associated development is defined within the same Section to mean development which is associated with an NSIP and "*is not the construction or extension of one or more dwellings*". The CLG *Guidance on associated development,* September 2009 explains that it is a matter for the decision maker to decide on a case by case basis whether or not development should be treated as associated development having regard to a number of principles which include:-

> *"Associated development should not be an aim in itself, it should be subordinate to and* ***necessary for the development and effective operation to its design capacity of the NSIP*** *that is the subject of the application". (paragraph 10)*

B.2.8 The guidance in paragraph 10 also explains that associated development is expected in most cases to be of a type normally brought forward with that sort of primary development and, for clarification, it could include "*measures necessary to mitigate the impacts of the primary development".*

B.2.9 Applying these principles to the HPC project, it is apparent that none of the proposed associated development is promoted as an aim in itself. All of the associated development is only promoted because it is necessary for the development and operation of the power station. Each of the associated development sites is the subject of development which is proposed at substantial costs to EDF Energy and which, in the majority is proposed to be removed at the end of the construction period. There is no other benefit to be derived from that development for the promoter than its use to serve the development of the power station.

B.2.10 The **Post Operational Strategy** (Appendix 4) sets out a framework for controlling the future of the individual associated development sites. With the exception of the permanent development of the Cannington Bypass and the improvements to the wharf facilities at Combwich, the Strategy identifies that the authorised use of the associated development facilities would fall away once their role in association with the construction of the HPC project is complete. Post Operational Schemes would determine closer to that time the extent to which it was sensible to remove all of the physical associated development from the individual site but the DCO application does not seek consent for their long term use. They are not proposed in the DCO application for any other purpose than to be subordinate to the NSIP. Apart from those facilities which are proposed to be permanent (the Cannington Bypass, the wharf improvements at Combwich) and the highway improvement works, there are no exceptions to this principle.

B.2.11 Whilst it is widely recognised that it may well be sensible and sustainable to retain the Bridgwater C campus buildings for future student accommodation, that proposal is not to be consented through the DCO. Instead, the **Post Operational Strategy** makes clear that any future use unassociated with the NSIP would need to be the subject of a planning application.

B.2.12 The only principal associated development sites where it is proposed to retain and use the development for the long term operation of Hinkley Point C are the Cannington Bypass and the improved wharf facilities at Combwich, although the lay down area would be removed and restored to open countryside. Both the bypass and the wharf have a continuing purpose in serving Hinkley Point C. The bypass would provide the primary route for daily operational traffic, whilst the wharf would continue to be important for the delivery of abnormal invisible loads during regular maintenance outages.

B.2.13 Whilst each of the associated development sites raises its own planning issues, the principle of providing associated development has not been controversial, with the exception of campus development, particularly at Bridgwater A. Otherwise, the response to consultation has generally welcomed the transport, freight and accommodation strategies which have sought to limit the impact of the HPC project on the local highway network and, for instance, on local housing resources.

B.2.14 The purpose of each element of the associated development is explained in Section 4 of this Planning Statement. The owners of the Bridgwater A site, however, have challenged the extent to which the accommodation campus can be promoted on the former Innovia site, *inter alia*, because it is suggested that the proposal may amount to the development of “dwellings” and may, therefore, be inconsistent with Section 115 of the 2008 Act. That assertion is the subject of on-going legal proceedings which will determine its merit. From a planning perspective, however, it may be helpful to briefly observe:

- case law clearly establishes important differences between dwelling houses and temporary accommodation which is more akin to barracks, hostels or holiday camps and the Town and Country Planning (Use Classes) Order 1987 makes a clear distinction between dwelling-houses, which fall under Class C3, and hostels which are not so categorised and, therefore, have been treated as being *sui generis*;
- the campuses are very different from other types of accommodation in the local area, particularly permanent family housing. They would be run by a Facilities Management Company using a centralised computer-based reservation system to provide temporary, short stay accommodation for construction workers and their operation in this respect would be similar to hotel accommodation with meals and communal facilities available to workers who would be able to book in for short or extended and sometimes intermittent periods;
- experience at Sizewell demonstrated that the campus accommodation was particularly popular with workers and its availability is known to be important to contractors who need the ability to attract a skilled and mobile workforce in large numbers at short notice; and
- because of their specific function, the accommodation campuses will be laid out in a very different form from traditional residential development. In particular each campus will be laid out in accommodation blocks, with around 35 workers living in individual rooms in each block, with shared amenities in a separate building. At Bridgwater A, for instance, this amounts to 25 separate accommodation blocks. This type of accommodation is not suitable for permanent residential accommodation.

B.2.15 Each element of the associated development proposals, therefore, can properly be considered as a part of the DCO application. Each element is necessary for the efficient and acceptable development of Hinkley Point C.

ii. Adverse Effects

B.2.16 Appendices 7-13 review the planning issues generated by development on the proposed associated development sites. In each case, the principal planning issues are identified and addressed and the principal residual issues are also identified and balanced against the benefits provided by the development of each site. The principal planning issues raised in the assessments are:

- conflict with local policy which aspires to the provision of permanent residential accommodation, rather than accommodation campuses;
- development on open countryside outside defined development boundaries; and
- detailed site specific issues.

B.2.17 The principle of providing temporary worker accommodation in campuses has been addressed above. It has been established through the Sedgemoor Core Strategy examination that the Core Strategy (and, therefore, also the draft Hinkley SPD) do not set policies or requirements for the HPC project. Instead, they express aspirations of the local authorities which carry no weight as planning policies. For the purposes of the consideration of the DCO application, it is more relevant to consider whether adverse impacts arise from the fact that the associated development proposals propose temporary rather than permanent residential accommodation. The analysis carried out within the appendices and that which is also set out in the **Accommodation Strategy** confirms that no adverse impacts are generated by the decision not to provide permanent residential accommodation as part of the DCO application.

B.2.18 Following the Stage 2 consultation, the local authorities asked EDF Energy to investigate whether it might be possible to construct family-style housing that could be used to accommodate construction workers and be left as a legacy for the local area. However, this investigation reinforced to EDF Energy the benefits of campus accommodation, which could not be delivered in permanent dwellings. Campus accommodation is specifically targeted at workers who want serviced accommodation, and feedback from contractors, suggests that this is what many workers would want. Those who want to stay in individual houses and do their own catering, laundry etc. would choose to stay in existing private rented sector stock. The full rationale for the use of accommodation campuses, rather than dwellings, to accommodate the workers during the construction phase is detailed in the **Accommodation Strategy**.

B.2.19 Turning to the question of development outside the established development boundaries, four of the sites (and the HPC development site itself) promote development on greenfield land, ie in countryside outside the designated boundaries for development within existing policy documents. This much is not surprising as the policy documents did not anticipate the development of Hinkley Point C or its designation in the NPS and did not set out to allocate land to meet its requirements. In fact, it would have been surprising if the project's development requirements could be satisfied within existing designated boundaries. If development is necessary for the development and effective operation of the NSIP, it will need to be provided and the relevant issues are not conformity with local policy but the extent to which actual harm arises from the development of the sites proposed.

B.2.20 The **Alternative Sites Assessment** (ASA) sets out in detail the considerable care which has been taken to select the proposed sites. It is clear from the ASA that a determined intention to limit adverse impacts has been one of the primary drivers of site selection. The other primary driver, however, has been the need to meet the functional requirements of the NSIP. As the ASA observes, there is no purpose in meeting a project specific need in the wrong location. The Cannington park and ride, for instance, has to be at Cannington, adjacent to the A39 and south of the village if it is to perform the function required of it by the Transport Strategy. Exactly the same principles apply to the other greenfield site proposals, ie junction 23, the Cannington bypass and the Combwich laydown area; they each respond to a specific requirement.

B.2.21 Opportunities have been taken where practical to correlate the functional need for the associated development with local planning policy designations. For instance, the Williton park and ride achieves both the functional need for a park and ride site to the west of Hinkley and the local policy aspirations to prefer brownfield land. The same principle arises in relation to the Somerfield site at Junction 24. Both sites were changed as a result of public consultation and their selection demonstrates the responsible and rigorous approach which has been taken to site selection.

B.2.22 As the ASA and the individual **Design and Access Statement** documents demonstrate, another feature of the project has been the careful evolution of site development in response to consultation and to the emerging outcomes of the **Environmental Statement**. The appendices record the changes made to all sites in response to these issues in order to refine the development proposals and to ensure where practical that their design avoids, limits and mitigates the potential impacts of each development. As a result of this approach, the appendices are able to record that there are relatively few significant adverse effects arising from the development of the associated development sites.

B.2.23 Of the associated development sites, perhaps the most sensitive in planning and environmental terms is the land at Combwich. As **Appendix 13** establishes, however, the site is required to meet a very specific and locationally inflexible requirement. Significant impacts do arise in relation to the visual impact of development in open countryside of the lay down area and significant noise impacts are likely to arise from the operation of the wharf. As the Appendix also explains, care has been taken to minimise these impacts through design and to mitigate them through screening, operational controls and through the provision of a noise insulation scheme. After the construction of HPC, the lay down area would be restored to open countryside. Whilst the proposed development of the land has generated concerns from local residents and the planning authorities, no better alternative sites have been proposed to meet the function which the land needs to perform in order to facilitate the construction of the power station.

B.2.24 Each of the appendices concludes that the benefit of the individual development outweighs its mitigated adverse effects. It is also necessary, however, to consider the contribution which each of the associated development sites makes to the HPC project as a whole. In particular, the following points are directly relevant:

- Each associated development site performs an essential function in mitigating greater impacts that would arise if the land was not developed. The absence of park and ride sites, for instance, would cause either extensive fly-parking across the travel to work area or the need for unsustainable and unsatisfactory car travel through urban and rural areas to the Hinkley Point C main development site, which would inevitably need to be expanded to provide a large car park (itself in open countryside).
- Similar considerations apply to the accommodation campuses – not only do they provide essential accommodation for the construction workforce, their development limits impacts on the local housing sector and brings direct advantages in terms of the ability to provide sustainable travel and to regulate worker behaviour.
- Without the associated development sites, there would be no HPC project – the impacts of the development would be substantially greater and the operational need to provide worker accommodation and to regulate freight deliveries and transport to the HPC development site could not be provided.

B.2.25 For all of these reasons, the collective impact of the associate development sites does not generate substantial adverse impacts to weigh in the overall planning balance.

b) HPC Development Site

B.2.26 Appendix 14 provides a review of the planning issues affecting the main development site. A detailed assessment of the likely significant effects of the construction, operation and decommissioning of the main development site is set out in the **Environmental Statement**, whilst the evolution and details of the design for the HPC development site is explained in the **Hinkley Point C Development Site Design and Access Statement** document.

B.2.27 The selection of the HPC development site is explained in Section 3 of this Planning Statement which reviews the site selection process undertaken by the Government in the preparation of NPS EN-6. That process also identified the potential for some significant environmental effects to arise from the development of the site with a nuclear power station but these potential effects were not considered a sufficient reason not to identify the site as potentially suitable within the NPS.

B.2.28 Confirmation that the main development site should be suitable in principle for the development of a nuclear power station is also provided by the fact that planning permission was granted in 1990 by the Secretary of State for a previous Hinkley Point C development following an extensive public inquiry.

B.2.29 More recently, WSC resolved to grant planning permission for extensive site preparation works in order to facilitate and bring forward the construction of the power station. That resolution, together with the intended grant and implementation of the permission would establish at least two relevant and important considerations for the IPC, namely:

- an acceptance by the local planning authority that the national imperative to provide a nuclear power station at Hinkley Point C is compelling; and

- the principal land – based impacts of the HPC development are already committed – ie impacts on archaeology and terrestrial ecology.

B.2.30 In fact, the consequences of a site preparation planning permission are even more significant. In particular, the resolution to grant permission for the site preparation works is a clear local acknowledgement of the likely overall acceptability of the HPC project as a whole. For instance, in relation to the landscape and visual impact of the future HPC project, WSC's resolution anticipates its effect and seeks to put in place preparatory mitigation to reduce its impact. Similar considerations arise in relation to other potential impacts of the HPC project. As part of the proposed Section 106 Agreement for the site preparation works, EDF Energy, WSC, SDC and SCC agreed to put in place a range of preparatory mitigation to address leisure, education, amenity, socio economic and accommodation impacts that would principally arise from the DCO project itself. There would be no purpose in those measures or in supporting the site preparation works if the HPC project was thought, in principle, to be unacceptable.

B.2.31 As with other elements of the HPC project, the relevant **Design and Access Statement** document identifies a meticulous approach to the evolution of the development proposals themselves in response to consultation and to the emerging learning generated by environmental and other assessments. As with each of the HPC sites, the emphasis has been to avoid, limit and mitigate impacts through scheme design.

B.2.32 The development of the HPC development site is necessarily a large-scale project which is subject to a high degree of technical specification and regulation. To a large extent, these requirements predetermine substantial elements of the scale and layout of the development. Perhaps for this reason, the local planning authorities have generated relatively little by way of informal policy for the main development site; concentrating instead on the associated development sites. The need to meet technical specifications, safety requirements and to ensure security are overriding considerations.

B.2.33 The inclusion of a 510 bedspace accommodation campus at the main development site has been the subject of controversy. The principal issues are addressed in the **Accommodation Strategy**, in the previous sections of this Planning Statement and in Appendix 14. The appendix identifies the obvious benefits of providing worker accommodation on site. Local residents have expressed concern about the potential implications of 510 workers being accommodated on site and this is understood to relate to fears for worker behaviour and/or a lack of integration between the workers and local residents. Appendix 14 explains the measures being put in place to ensure high quality management of the workforce. The concerns expressed are undoubtedly genuine but they do not translate into tangible planning objections, particularly compared with the alternative which would be to disperse the workforce in less controlled and co-ordinated accommodation throughout the local villages.

B.2.34 The **Habitats Regulations Assessment** considers in detail the potential for the HPC project to adversely impact upon the integrity of European protected sites. No such impact is predicted to arise.

B.2.35 The **Environmental Statement** reviews all other potential environmental effects and the principal identified impacts are reviewed in Appendix 14. Because of the care taken with scheme design and proposed mitigation, the residual environmental effects identified are relatively limited for the scale and importance of the project.

B.2.36 As anticipated in the assessment summarised in Annex C of NPS EN-6, there are landscape and visual impacts which cannot be entirely mitigated. As Appendix 14 explains, however, the early implementation of landscape and screening particularly to the south of the site and on its western boundary limit construction impacts.

B.2.37 Once the HPC development is complete the majority of landscape and visual impacts would decrease due to removal of construction machinery and the restoration of the landscape, although some significant adverse impacts would remain in the local area due to the large scale of the completed HPC development which cannot be completely screened by landform or vegetation, particularly when viewed from elevated areas.

B.2.38 The landscape impacts during operation would be predominantly minor adverse due to the landscape restoration scheme which would introduce a number of valuable landscape features within the site.

B.2.39 In the residential areas closest to the application site, where landscaping including landform and vegetation has the highest screening potential, the majority of visual impacts would be adverse and of moderate significance. However, due to the proximity of the HPC, localised major adverse impacts would remain for users of PRoW along the coastline adjacent to the site. Some of these impacts would slightly decrease in the long term, when the planting proposals, including off-site mitigation measures, mature.

B.2.40 The majority of permanent visual impacts on viewers from within the Quantock Hills AONB would be minor adverse, although a localised area of moderate adverse visual impact would exist in the north-eastern part of the AONB due to its high elevation and the angle of view. The visual impacts on viewers located approximately 8km and beyond would not be significant.

B.2.41 In principle, this scale of impact is not different from that anticipated in the NPS, although local impacts may be less than may have been expected due to the proposals to bring forward early screening in the south of the site.

B.2.42 Screening, operational controls and distance ensure that the noise and air quality effects on local communities are likely to be acceptable. In any event, EDF Energy has proposed a **Main Site Neighbourhood Support Scheme** to provide noise insulation and a Property Price Support Scheme for residents in Shurton, Burton, Knighton, Wick and Stolford in recognition of the fundamental change which the project will bring to the immediate vicinity of the site, even if that change does not generate direct adverse amenity impacts.

B.2.43 Mitigation proposed as part of the Site Preparation Works Section 106 Agreement already addresses the need to divert affected rights of way and to mitigate the impact on local recreation by upgrading public rights of way nearby. The extensive programme of PROW improvements proposed as part of the site preparation works is intended to be extended in the **Heads of Terms for the DCO Section 106 Agreement** (Appendix 15), so that the HPC project should bring a net benefit in the quality of local rights of way. In addition, in excess of 100 ha of land in the southern part of the development site would be landscaped and enhanced as a nature reserve with public access, making a significant contribution to enhanced local biodiversity and amenity.

B.2.44 As with all aspects of the HPC project, therefore, the careful approach to design and mitigation does mean that the residual impacts of even the development of the development site are relatively limited given the scale and importance of the project.

B.3 REQUIREMENTS AND OBLIGATIONS

B.3.1 EDF Energy consulted on a suggested approach to the principal Requirements and Obligations that may be relevant to Hinkley Point C as part of its Stage 2 consultation in summer 2010 and on further suggested changes as part of its Stage 2A update consultation in spring 2011. Since that time, EDF Energy has continued to develop its proposals for development consent obligations. These considerations have been particularly informed by:-

- feedback from its consultation exercises and from continuing engagement with communities and stakeholders;
- the detailed discussions that have taken place around the now agreed terms for planning obligations to be associated with the Site Preparation works on the HPC development site; and
- the results of the environmental impact assessment and other assessments undertaken for the DCO application, which have been referred to in the previous two Sections of this Planning Statement on a project wide and site-specific basis.

B.3.2 As a result, the proposed **Heads of Terms for the Section 106 Agreement** have been drawn up and are explained in this Section of the Planning Statement.

B.3.3 In addition, requirements have been drawn up to form part of the draft DCO. Draft requirements were circulated to statutory consultees for comment and have been developed further with the benefit of that exercise but also to capture the mitigation required to secure the robustness of the environmental and other assessments which accompany the DCO application.

a) Relationship to the Site Preparation and Jetty applications

B.3.4 The draft requirements and obligations for the DCO application have been prepared with the benefit of the discussions that have taken place with stakeholders over the terms of conditions and obligations for the two preliminary works applications – ie. for the Site Preparation application to WSC and the jetty applications. Against that background it is relevant to confirm the following:

- the draft DCO includes both the Site Preparation and the Jetty developments for the reasons explained in Section 4 of this Planning Statement. Conditions that might be applied to those permissions, therefore, need to be included in the DCO where appropriate;
- whilst both may have been consented and implemented before the DCO itself may be granted, EDF Energy proposes that all land–based construction activity should be carried out and regulated under a single consent; namely, under the DCO. It is proposed, therefore, that the conditions imposed on the Site

Preparation and the land-based Jetty works would fall away in the event that the DCO is consented and that all works would then be regulated under the DCO instead;

- in most cases EDF Energy has carried forward the drafting of conditions for the Site Preparation and the Jetty works into the DCO requirements; but in some instances changes have been made. Those changes either result from the need to codify a clear set of requirements so that they are appropriate to a single project, or they arise from matters which EDF Energy considers necessary change from the previous consents. An example of the latter category is the requirement relating to hours of working where EDF Energy has consulted on more extensive working hours in the event that the DCO application is consented;
- EDF Energy has committed itself, however, to observe the terms of the Site Preparation Section 106 Agreement for the duration of the Site Preparation Works in the event that the Site Preparation works application is granted and implemented. The Section 106 obligations proposed for the draft DCO, therefore, assume the grant of the Site Preparation permission and its implementation, so that the draft Heads of Terms for the DCO Section 106 Agreement are additional and complementary to the Site Preparation obligations; and
- the one exception to this relates to the provisions for reinstatement, where EDF Energy proposes a different approach – see further below.

B.3.5 This means that, in some topic areas, further obligations to be entered into in relation to the DCO are relatively limited because much of the mitigation will already have been secured in the event that the site preparation planning permission is granted and implemented.

i. Relevant Guidance: Obligations

B.3.6 National policy in respect of planning obligations and the approach to the mitigation of impacts for Energy NSIPs is set out in NPS EN-1. As the NPS makes clear (para. 1.7.2), the development of new energy infrastructure is likely to have some negative effects, not all of which it will be possible to mitigate. Guidance is provided on a topic specific basic on the approach to be taken to the assessment and mitigation of impacts, but the overriding policy principles are set out paragraph 4.1.8 which provides:

> *“The IPC may take into account any development consent obligations that the applicant agrees with local authorities. These must be* ***relevant to planning, necessary to make the proposed development acceptable in planning terms, directly related to the proposed development, fairly and reasonably related in scale and kind to the proposed development and reasonable in all other respects****.” (emphasis added)*

B.3.7 Interestingly, the NPS does not defer or refer to any other guidance, law or policy in this respect – this is the statement of policy for NSIP development consent obligations.

B.3.8 The appropriate approach has been the subject of some debate with the Local Planning Authorities – particularly in relation to the draft text and policies of the Sedgemoor Core Strategy and the Hinkley SPD (see earlier para. 6.3.6). In particular, EDF Energy resisted the general expectation in the submitted draft Core

Strategy that "compensation" should be provided to offset any adverse impacts of the project. Following the Core Strategy examination, SDC made changes to the draft Core Strategy to remove such references.

B.3.9 For the purposes of this application, the terms of NPS provide the primary policy guidance. The NPS ENV-1 provides at paragraphs 4.2.2-3:

> *"The (EIA) Directive requires an assessment of the likely significant effects of the proposed project on the environment, covering the direct effects and any indirect, secondary, cumulative, short, medium and long-term, permanent and temporary, positive and negative effects at all stages of the project, and also of the measures envisaged for avoiding or mitigating significant adverse effects.*
>
> *To consider the potential effects, including benefits, of a proposal for a project, the IPC will find it helpful if the applicant sets out information on the likely significant social and economic effects of the development, and shows how any likely significant negative effects would be avoided or mitigated."*

B.3.10 Two matters to be drawn from these paragraphs are i) that it is only "*significant*" effects which are expected to be addressed (where they can be) and ii) that such effects are to be avoided or mitigated; there is no generalised requirement to compensate unmitigated impacts. Similar guidance is provided throughout the NPS. Part 5 of the NPS provides advice to the IPC on "*Generic Impacts*". In each case, the NPS sets out expectations for the applicant's assessment, for IPC decision making and for mitigation. The list is not exhaustive but paragraph 5.1.2 provides that the IPC should consider other impacts and means of mitigation where it determines that the impact is relevant and important to its decision.

B.3.11 Specific reference to "compensation" is provided at paragraph 5.3.7; in a context where significant harm to biodiversity cannot be avoided through alternatives or mitigation, compensation measures should be sought. This principle of compensatory habitat is familiar through PPS 9 and through Habitats Assessments and has been observed where required in the HPC project. Otherwise, however, EDF Energy's approach has been to seek to limit adverse effects through project design and to mitigate those significant effects that cannot be avoided. Any residual impacts fall to be considered in drawing the overall balanced judgement required by Section 104 of the Planning Act 2008, i.e. whether the adverse effects outweigh the benefits of the project.

ii. Draft DCO Section 106 Heads of Terms

B.3.12 The draft Heads of Terms for the development consent obligations have been drawn up on the basis of the principles set out above, having regard to the assessed impacts of the development and they are explained below under a series of headings, in alphabetical order.

B.3.13 Before doing that, however, there are three important matters to explain in relation to the Site Preparation works Section 106 Agreement:

- the site preparation works themselves required mitigation principally in relation to their land based impacts – ie. impacts generated by the clearing and preparation of the main development site itself – for example in relation to archaeology or ecology. The scale of transport or socio-effects was assessed to be relatively limited

- the opportunity was taken, however, for EDF Energy to commit to other obligations which would assist in the mitigation of the impacts of the HPC project itself and, in particular, to put in place measures which would assist in mitigating impacts that might arise early in the construction of the HPC project. These measures related, for instance, to early highway improvements or early investment in local housing initiatives. In the same way that the application proposed preparatory works to bring forward the project, the opportunity was taken to bring forward some elements of mitigation for the project as well;
- EDF Energy has been open about the purpose of the preparatory mitigation and its purpose was advised in the officer's report to committee, with appropriate weight being given to those aspects which did not relate directly to the impacts of the site preparation works themselves.

B.3.14 EDF Energy did not propose the terms of some of the obligations required by WSC but the Section 106 Agreement was drawn up based on the terms resolved by the Planning Committee. EDF Energy's alternative course of action would have been to appeal the application for non-determination and to argue for different terms at a planning inquiry. The urgency of the project, however, including the need to undertake some works within the appropriate season (to respect relevant bird and bat seasons), militated against further delay of an application which had originally been submitted in November 2010.

B.3.15 Notwithstanding the above, EDF Energy has undertaken not to seek to use the DCO process to alter the Site Preparation obligations, the majority of which are limited in duration to a two-year period following commencement of the site preparation works, as long as planning permission for Site Preparation is granted and implemented.

B.3.16 There is, however, one exception to this which relates to the obligations for site reinstatement, which EDF Energy has made clear it does not consider should apply to any DCO consent. The position in this respect is explained briefly below:

- The planning application for the site preparation works stated that in the event those works are implemented but not required, because a DCO is not subsequently granted for the project, then EDF Energy would completely remove all installed infrastructure and would reinstate the application site to its previous condition.
- The planning application included a Landscape Reinstatement Strategy, which sets out EDF Energy's proposals for the reinstatement of the site in the event that the DCO is not granted.
- A planning condition dealing with reinstatement was put before the Planning Committee and members resolved to grant planning permission on that basis. Negotiations on the form of planning conditions and planning obligations have continued since the committee meeting. The conditions go beyond the period in which the Site Preparation works will be carried out and provide for the site to be reinstated in full in the event that a DCO is granted and implemented, but neither of the nuclear reactors authorised by that order has been substantially completed and generating electricity by 31 December 2025. It is therefore possible that the

power station could be 90% complete on that date, but EDF Energy would nevertheless be compelled to remove all of the buildings constructed on the site and to reinstate the land.

- The Site Preparation planning obligation provides for EDF Energy to provide security of £63,000,000 for these reinstatement obligations by way of a bond and/or an escrow account. The Council may draw on this sum in the event that EDF Energy is in breach of its reinstatement obligations as set out in the planning conditions. As drafted, this security will need to remain in place throughout the period that the reinstatement obligations are "live" – ie. until potentially 31 December 2025.
- EDF Energy's position is that it should be entitled to vary the reinstatement obligations and security arrangements through the DCO process. Indeed, Informative 25 to the draft Site Preparation planning permission specifically contemplates this possibility. The most recent version of the draft Section 106 agreement for the site preparation works now provides that EDF Energy must comply with the reinstatement obligations set out in the draft planning permission unless they are expressly varied, removed, abrogated, modified or superseded by any lawful means.
- The draft Section 106 Agreement for the site preparation works contains the parties' acknowledgement that EDF Energy may apply to vary, modify or supersede the reinstatement obligations and EDF Energy has given the Council notice of its intention to vary those obligations through the DCO, the draft of which provides for no reinstatement obligations. It is EDF Energy's position that maintaining these obligations once the DCO has been granted and implemented would be inappropriate. The Funding Statement provided with the DCO application provides sufficient protection against the remote prospect of a half completed nuclear power station and that there is no expectation in the NPSs (or other guidance) that projects must guard against the extreme possibility of partial development.

B.3.17 Against this background, the terms of the proposed DCO planning obligations are explained below. A Schedule identifying the proposed **Heads of Terms for the Section 106 Agreement** and recording those already proposed in the draft Site preparation Section 106 Agreement is contained at **Appendix 15**.

i. Accommodation

B.3.18 As part of the Section 106 agreement for the site preparation works application , EDF Energy is to commit to the following:

- a series of local education, training, outreach and recruitment initiatives to maximise the opportunity for local people to gain employment in the construction and operation of Hinkley Point C, i.e. people who are already accommodated in the local area;
- the establishment of an Accommodation Office to provide a service to local people and businesses who wish to offer accommodation to the incoming workforce; to provide details of accommodation available in the local area to the workforce and to try and match the accommodation requirements of the incoming workforce to the available local supply where practical;

- a Housing Fund of £4 million, made available to the planning authorities to stimulate new supply in the private rented sector; to bring empty homes back into beneficial use through improvement grants; to support rent deposit schemes, and equity loans to assist local people in securing accommodation and to provide funding for local new build housing schemes, including subsidising the provision of affordable housing.

B.3.19 As part of the DCO application, EDF Energy is seeking approval for the construction of three construction worker campuses (on site and at Bath Road, Bridgwater) for 1,510 workers' bed spaces. Research into the availability of potentially available local accommodation in the housing and bed and breakfast sectors suggests that this supply, in combination with the proposed campuses will be sufficient to meet the requirements of the incoming workforce without adverse impacts on the local housing market.

B.3.20 Rather than simply trusting that this will be the case, however, the Housing Fund has been proposed as "advance mitigation", i.e. to be used to put in place measures to assist local households and to bring forward additional local accommodation in case an impact does arise when the peak of the construction workforce arrives in the area. EDF Energy's research suggests that a housing fund of £5 million would be sufficient to create at least 1,000 additional bed spaces locally. The down payment of £4 million as part of the Site Preparation Section 106, therefore, allows early assistance to be provided to meet any potential future impacts.

B.3.21 For the DCO Section 106, it is proposed to top up the Housing Fund by an additional £1 million, i.e. to complete the fund at a total of £5 million. EDF Energy will put in place measures to ensure that this additional funding is spent efficiently and in areas where any incremental impact is most likely to arise.

B.3.22 In addition, EDF Energy will undertake monitoring to ensure that the clustering of the new workforce in particular settlements does not generate local housing difficulties. EDF Energy's **Accommodation Strategy** sets out triggers for individual groups of local communities. Where monitoring identifies the clustering of workers beyond those trigger points, additional contributions would be made to the Housing Fund.

ii. Community Impact

B.3.23 EDF Energy consulted on the principle of a Community Impact Fund at Stage 2 and the purpose of the Fund has remained consistent since that time. As explained at Stage 2, every effort has been made to identify, limit and mitigate impacts which can be identified at this stage from the DCO development. EDF Energy accepts, however, that there are likely to be other less easily defined impacts which will be felt by local communities and which may not be addressed by the full range of other mitigation commitments. These less tangible impacts might be described as impacts on the "quality of life" of local communities.

B.3.24 It is far from clear that such impacts will necessarily arise in net terms. Whilst the construction and operation of Hinkley Point C will inevitably bring about changes in some local communities, many of those changes will be very positive – particularly the increased economic prosperity that the investment will bring to the local area, which will be maximised through the commitments to education, training and to local procurement. Other Section 106 obligations will also bring benefits in terms of enhancements to local amenities such as public rights of way, leisure facilities etc.

B.3.25 Nevertheless, other adverse changes cannot be ruled out and EDF Energy has always thought it appropriate to offer a local Community Impact Fund. The intention is that the Fund would be spent on local initiatives which enhance the quality of life in settlements that may be affected by Hinkley Point C. EDF Energy's vision for this fund is very much that it should be spent by and on behalf of local communities. EDF Energy does not wish to direct how the Fund should be spent and believes that the communities themselves would be best placed to determine how the availability of funds can best be used to enhance the local quality of life. Accordingly, the scope for the Fund is widely defined so that it may be spent on a range of initiatives including such things as improvements to local facilities, funding local events, sponsoring local initiatives and assisting local causes.

B.3.26 As part of its Stage 2 A consultation, EDF Energy proposed an increase in the fund to £20 million and this remains in EDF Energy's view the appropriate scale of the fund.

B.3.27 As part of the site preparation planning final draft Section 106 Agreement, a down payment of £4 million from the Fund is to be committed, together with two additional annual payments of £1.6 million, ie a total of £7.2 million out of the total fund of £20 million. Similarly, as part of the terms of resolving to grant the site preparation consent, the local planning authorities determined that the Fund should be controlled by a board of 8 representatives (two each nominated by West Somerset, Sedgemoor, Somerset County Council and EDF). The board would receive bids from local communities and others and determine the apportionment of the Fund, with the decisions of the board being ratified by the cabinet of West Somerset Council.

B.3.28 EDF Energy will review the governance structure of the Fund as part of the DCO process in order to ensure that it is effective in meeting the purpose of the Fund, which is to recognise the particular role of local communities and to ensure that the money is spent as the local communities would decide. For the DCO, therefore, EDF Energy will review the governance structure for the residual £12.8 million of the Funds (which would be made available in annual payments throughout the construction period) in discussion with local communities, the local authorities and other stakeholders.

iii. Community Safety

B.3.29 As part of the site preparation Section 106 Agreement, EDF Energy committed to pay up to £1.82 million to the local authorities and to the Emergency Services to be spent on a range of initiatives including:

- Local Authority Community Safety Officers who would work in the local community to address any issues of integration between Hinkley workers and the community.
- Funds for the local authorities to create plans for the management of any incidents arising at Hinkley, including evacuation plans.
- Funding the Police to provide a Community Safety Beat Team, as well as additional funds for the Police to assist in dealing with any incidents or protests and to prepare detailed plans for incidents which may arise during the DCO construction works.
- Funds for the Fire Service to undertake specialist training, site familiarisation and incident planning.

- Funds for the Ambulance Service to do likewise.

B.3.30 For the DCO obligations, EDF Energy proposes to continue similar initiatives with additional funding of £3.84 million, again spread between the local authorities and the emergency services over the construction period. A spreadsheet indicating the breakdown of these funds is attached with Appendix 15.

iv. Ecology

B.3.31 EDF Energy's principal approach to the ecological impacts of the project is to limit those impacts through the careful design of the project and to mitigate any adverse effects through on site ecological enhancements. This approach is consistent with the guidance provided at paragraph 5.3.6 of NPS EN-1.

B.3.32 As part of the site preparation Section 106 agreement, EDF Energy committed to the following:

- off site habitat enhancement to offset any potential impact on bats which may arise from the loss of habitat on the HPC development site;
- a contribution of £250,000 to West Somerset Council to be spent on additional off site habitat enhancements in the local area such as tree planting and hedgerow improvements; and
- a commitment that EDF Energy would undertake comprehensive tracking of bats in the local area in order to inform the extent of any additional obligations necessary for the DCO.

B.3.33 The environmental impact assessment work for the DCO, including the cumulative impact assessment, has not identified the need for any additional off site enhancements, with the potential exception of bat habitat, the scale of which will be informed by the radar tracking of bats to which commitment is made through the Site preparation Section 106.

v. Economic Development

B.3.34 It cannot seriously be disputed that the investment in Hinkley Point C will bring significant benefit to the local economy. As a result, there are no adverse local economic effects to mitigate.

B.3.35 Nevertheless, EDF Energy is committed to ensuring that local benefit is gained from the Hinkley Point C investment. Accordingly, EDF Energy is committed to a determined Local Business Engagement Strategy. For some time, EDF Energy has been working closely with Somerset Chamber of Commerce and with the local authorities to ensure that local companies have maximum opportunity to bid for contracts at Hinkley Point C. This work is explained in the **Local Project – Supply Chain Engagement Strategy.**

B.3.36 As part of the site preparation Section 106 Agreement, the local authorities have required additional investment in economic development and EDF Energy undertook to provide funds of £617,880 to be spent by the local authorities on engagement of Economic Development Officers and funds for business support initiatives, which are intended to build local business resilience and address barriers to growth. .

B.3.37 As part of the DCO obligations, EDF Energy proposes to continue with its own initiatives and, in addition, to provide funds to the local authorities for the continued engagement of an Economic Development Manager over the construction period to ensure maximum integration between local businesses and the EDF Energy procurement team.

B.3.38 In addition, EDF Energy proposes to provide funds of £320,000 to the local authorities to assist in the continuing work of promoting and developing a Somerset and South West low carbon cluster. Those funds would be available to be spent on studies, bids and engagement with potential partners and relevant stakeholders in order to maximise the inward investment opportunity created by the Hinkley Point C development.

vi. Education

B.3.39 Again, EDF Energy has committed to its own **Education Strategy**, known as "Inspire" – the purpose of which is to work in local schools to inspire interest in science, technology, electronics and mathematics. The principles of the Education Strategy have been agreed with the County Council as part of the site preparation planning application and the Strategy is already being implemented. EDF Energy has appointed an education co-ordinator and has committed expenditure of more than £300,000 in the period 2011-2014. The strategy involves outreach visits to schools in the County but, particularly, in Sedgemoor and West Somerset along with the provision of teaching aids and resources to stimulate student interest. The Inspire strategy is effectively the first part in a comprehensive package of education, training and employment aimed at securing the local benefits of Hinkley Point C.

B.3.40 In the event of consent for the DCO, EDF Energy would commit to continuing the operation of the Inspire strategy at least for a further two years at a cost of £200,000 in addition to the cost of £300,000 committed as part of the site preparation application. The continued roll out of the Strategy would be reviewed after that time.

B.3.41 EDF Energy is also aware of the potential for incoming construction workers to bring families that may place pressures on local schools (see earlier paragraph 7.2.26). Accordingly, EDF Energy proposes:-

- to monitor the home location and school location of Hinkley Point C worker children;
- to work with Somerset County Council to monitor the take up of school places by Hinkley workers children relative to the available supply of school places;
- to commit to a formula consistent with existing County Council policy which allows parents to have the right to nominate up to 3 schools where the local school is at capacity. If capacity is unavailable within that framework, EDF Energy would fund the provision of additional school places. In doing so, the cost multiplier normally used by the County Council for permanent housing would be reduced by 50% to reflect the temporary nature of the Hinkley impacts;
- to protect against any potential for adverse effects arising, EDF Energy would commit to an advance payment of £610,000 to fund new temporary or improved class rooms in Bridgwater and Cannington; and

- in addition, EDF Energy will fund a teacher post at a cost of up to £60,000 per annum for 5 years following the grant of DCO consent whose responsibility would be to oversee the integration of Hinkley workers' children into local education.

B.3.42 This is considered to be a comprehensive package of commitments which would both maximise the education benefit and opportunity provided by the Hinkley Point C investment and would ensure that no adverse impacts on local education arise.

vii. Health

B.3.43 In order to reduce potential impacts on local health services from incoming construction workers, EDF Energy has committed to comprehensive occupational health services for construction workers by engaging the health contractor Duradiamond and by providing on site medical facilities at the main Hinkley Point C site. In this way, potential impacts on local health services should be limited to referrals to the NHS where the on site team is unable to deal with specific incidents or conditions, to ambulance call outs and to the potential impacts arising from the families of workers attracted to the area during the construction period. EDF Energy proposes to comprehensively mitigate these potential impacts.

B.3.44 As part of the site preparation Section 106 Agreement, EDF Energy would commit to fund a Hinkley Readiness Study for £60,000 which would enable the health services to prepare properly for the Hinkley Point C development. As part of the DCO Section 106 Agreement, EDF Energy intends additionally to commit to:-

- a formula to fund ambulance call out costs, estimated to be in the region of £134,000;
- a formula also to cover the potential cost of additional NHS referrals from construction workers, estimated to cost £50,460; and
- a phased payment estimated at £793,450 to the Primary Care Trust to address any additional costs of dealing with the health requirements of workers families – even though those families are expected to take up existing housing accommodation.

B.3.45 In addition, a **Health Impact Assessment** and a **Health Action Plan** have been prepared for the DCO application. EDF Energy will undertake the measures set out in the Health Action Plan, which includes those measures set out above, together with a range of community initiatives aimed at limiting any harm on community well being (see earlier Section 7.3).

viii. Heritage and Archaeology

B.3.46 The principal archaeological impacts of the HPC development arise from the site preparation works. Accordingly, as part of the site preparation Section 106 Agreement, a fund of £450,000 was committed to the County Council to be spent on the following:

- £55,000 to be spent on detailed archaeological monitoring of the site preparation works;

- £160,000 to be spent on archaeological outreach and education, ie on show casing the results of the archaeological excavation and extending learning locally from the information gathered as part of that excavation; and
- £245,000 to be spent on public realm heritage improvements in the local area. In particular, funds are to be spent against a detailed programme of activity agreed with the County Council which would see improvements to public realm heritage assets along road corridors in Cannington and Bridgwater.

B.3.47 The environmental impact assessment for the DCO has not identified any substantial additional adverse effects on archaeology or heritage arising from the DCO proposals themselves. Some limited additional adverse effects do arise, however, for instance from the construction of the Cannington Bypass. As a result, EDF Energy proposes to offset these impacts through a contribution of £300,000 which would be applied towards the restoration of Castle House in Bridgwater which is identified as a significant heritage asset at risk.

ix. Landscape and Visual Impacts

B.3.48 EDF Energy acknowledges that the construction of the power station at Hinkley would have landscape impacts locally as well as impacts in longer range views, for instance, from the Quantocks AoNB. Whilst the Government is aware of these potential impacts, it has identified the site of Hinkley Point C as potentially suitable for a new nuclear power station and it recognises that it is unlikely to be possible to fully mitigate the impacts. In other words, some adverse effects are recognised as a necessary consequence of the development. Nevertheless, EDF Energy has worked hard to limit any local or more distant adverse effects through the detailed design of the power station itself and through the careful design of its landscaping proposals, which include significant ground shaping in order to screen lower level "clutter" of the development to help integrate the development into the surrounding landscape.

B.3.49 As part of the site preparation Section 106 Agreement, EDF Energy has agreed to a range of initiatives in recognition of the potential visual impact of the development and in order to put in place advance mitigation in anticipation of the DCO project. Those commitments include:

- £100,000 to establish a Quantock Hills and Vale Landscape Development Fund – to support projects which restore or develop landscape features within the AONB;
- £250,000 to establish a Landscape Improvement Scheme to deliver area wide landscape improvements that provide landscape corridors;
- £80,000 for public art projects to add to the local landscape; and
- £120,000 for the establishment of a Development of a Land Management and Skills scheme, to fund the learning of traditional landscape and countryside skills.

B.3.50 In addition, EDF Energy is proposing to fund through the site preparation Section 106 a landscape officer whose job it is to oversee the implementation of the various funds.

B.3.51 As part of the DCO application, EDF Energy is committing to a detailed landscaping strategy and also proposes to continue with funding for the landscape officer for a further 5 years and to provide an additional £40,000 per annum to the landscape funds established through the site preparation works consent.

B.3.52 In this way, EDF Energy considers that it is comprehensively addressing the potential visual impacts of the development in the most appropriate way. NPS EN-1 and EN-6 recognise that there would inevitably be some landscape and visual impacts that cannot be fully mitigated (see, for instance, NPS EN-1 paras. 1.7.2, 1.7.11, 5.9.8, 5.9.13, 5.9.15 and C.5.67 as well as NPS EN-6 paras. 3.10.3 and 3.10.8). Nevertheless, EDF Energy is doing what it reasonably can to mitigate those impacts.

x. Leisure

B.3.53 Leisure impacts potentially arise in two ways from the Hinkley Point C project. In principle, some of the elements of the development could result in the loss of existing leisure facilities, whilst the influx of construction workers could also add to the demand for local leisure services and facilities. These issues have been directly addressed in the **Environmental Statement** and summarised earlier at paragraph 7.2.45.

B.3.54 In order to anticipate these impacts and to put in place measures to mitigate them before they arise, EDF Energy committed to a comprehensive set of obligations as part of the site preparation Section 106 Agreement, i.e.:

- £250,000 towards the construction of a new swimming pool in Bridgwater;
- £500,000 to provide new playing fields and social club facilities or to improve existing facilities in Bridgwater to offset the loss of such facilities at the former Innovia site which is to be used for a construction workers' campus as part of the DCO project;
- £250,000 to be spent on improving existing sports facilities or providing new sports facilities in the district of West Somerset; and
- £500,000 to be spent in Cannington and £500,000 to be spent in Stogursey parishes on new or improved sports/leisure facilities.

B.3.55 In total, this commitment of £2 million is considered to be sufficient to offset any potential adverse effects arising from the introduction of construction workers into the local area (see earlier Section 7.2 v). By making the money available through the site preparation Section 106 Agreement, advance mitigation could be put in place before impacts arise.

B.3.56 In addition, EDF Energy is providing sports and leisure facilities on its principal campuses at Hinkley Point and at Bridgwater A in order to provide facilities for workers and is committing to ensure that these facilities are made available to the general public.

xi. Rights of Way

B.3.57 Construction of Hinkley Point C would cause the permanent loss of some public rights of way which cross the HPC development site and the temporary loss of a number of other rights of way which would be affected during the extensive construction period. These impacts arise from the start of the site preparation works. Accordingly, EDF Energy committed has to a substantial package of rights of way improvements as part of the Section 106 Agreement for the site preparation works.

B.3.58 That agreement commits EDF Energy to fund up to £539,000 of public rights of way improvement against an agreed **Rights of Way Restoration and Enhancement Plan** which was originally prepared by Somerset County Council. It is the role of the County Council to implement those improvements drawing on the fund provided by EDF Energy.

B.3.59 Limited additional impacts arise from the DCO itself and few rights of way are directly affected by the associated development works, although one right of way is impacted by the construction of the Cannington Bypass and others may be judged to have their setting affected. Accordingly, EDF Energy proposes to extend the Rights of Way Restoration and Enhancement fund by an additional £199,000 in order to fund:

- further improvements to the coastal path westwards from Hinkley to Kilve, contingent upon agreement with the relevant land owners, using powers available to Natural England;
- further upgrading the coastal path where it extends from Stolford to Steart; and
- upgrading the Parrett Trail which runs on the west bank of the river Parrett, as far as Bridgwater.

B.3.60 In this way, the construction of Hinkley Point C is expected to result in a substantial net improvement to the scale, range and quality of the rights of way network.

xii. Skills and Training

B.3.61 The effects of Hinkley Point C on the local potential workforce are all expected to be positive. As with economic development, there is no adverse impact to mitigate. These issues are revised at 7.2 of this Planning Statement.

B.3.62 Nevertheless, EDF Energy is committed to securing the local economic benefits of Hinkley Point C and to ensuring that every opportunity is given to the local workforce to take advantage of the investment. Accordingly, EDF Energy is committed to its own comprehensive programme of skills and training and has recruited a specialist team to ensure maximum benefit.

B.3.63 As part of the site preparation Section 106 agreement, EDF Energy would commit to a range of self funded activities, together with funds of £4.68 million made available to the local authorities and local education providers to achieve the following:

- construction by Bridgwater College of a new Construction Skills Centre at Cannington;
- investment in the existing Energy Skills Centre at Bridgwater College in order to enhance its capacity;
- physical and curriculum improvements at West Somerset Community College as part of a Hinkley Ready Project in order to enable the college to offer relevant training and apprenticeship courses;
- investment in an Enterprise Project to be undertaken also by West Somerset Community College in order to enable local people to gain the necessary skills to provide services to the construction and operational workforce;
- an Employment and Skills Officer to be employed by the local authorities but seconded into the EDFE Employment and Skills team;

- two Community Outreach Workers to support local people and to overcome difficulties which some people have accessing work – this includes commitment to a Fit to Work programme; and
- a Young Persons' Support Worker to improve the life chances of young people and to improve their ability to access the opportunities at Hinkley Point.

B.3.64 To underline its commitment to these and related initiatives, as part of the DCO Section 106 Agreement, EDF Energy proposes further investment into a range of activities including the measures and projects set out in the **Construction Workforce Development Strategy** and:

- a further £2 million to further enhance the Bridgwater College Energy Skills Centre;
- the establishment of a comprehensive Employment Brokerage;
- the continued engagement of the two Community Outreach Workers and the Young Persons' Support Worker for a further 4 years; and
- the continued engagement of the specialist employment and skills team in order to maximise the activity and benefits of the employment brokerage and to ensure its integration with the other training initiatives.

xiii. Tourism

B.3.65 EDF Energy does not expect the construction of Hinkley Point C to adversely affect the local tourist economy (see earlier para 7.2.20). Indeed, the influx of construction workers throughout the year will bring significant benefits to the local bed and breakfast and catering economy, whilst the construction of the exemplar Public Information Centre at Hinkley Point will provide a substantial new tourist attraction to showcase not only Hinkley Point C but also the wider attractions of the county of Somerset.

B.3.66 As part of the resolved terms for the site preparation Section 106 Agreement, the planning authorities required EDF Energy to invest in payments to the Councils to provide Tourism Management Officers, to fund the preparation of a Tourism Strategy and to fund additional marketing and promotion initiatives which will anticipate the benefits of and any impacts of the Hinkley Point C development.

B.3.67 EDF Energy has also committed to provide a public information centre in Bridgwater throughout the construction period of the site preparation works.

B.3.68 EDF Energy does not propose to fund additional initiatives as part of the DCO Section 106 Agreement although it remains fully committed to:

- an exemplar Public Information Centre at Hinkley Point C; and
- the public information centre in Kings Square, Bridgwater remaining open throughout the construction period of the project, to provide a point of contact for the community and visitors to the area who have an interest in the Hinkley Point C project.

xiv. Transport

B.3.69 EDF Energy recognises that no construction project of the scale of Hinkley Point C can be undertaken without generating significant traffic – traffic both to carry the large quantities of construction materials and traffic generated by the construction workers themselves.

B.3.70 Accordingly, EDF Energy is committed to a comprehensive **Transport Strategy** which seeks to reduce the impact of construction activity with the following principal initiatives:

- maximising where practicable the use of the sea to bring construction materials to Hinkley through the development of a temporary jetty and through the refurbishment and enhancement of Combwich Wharf;
- limiting the amount of car parking at the HPC development site and providing four park and ride sites at strategic locations to intercept traffic;
- a comprehensive bus strategy serving principal settlements and also serving the park and ride sites; and
- two freight management facilities located at junctions 23 and 24 of the M5 to intercept lorry traffic and to hold it so that the volume of freight traffic using the local road network during the peak periods is minimised as far as practicable.

B.3.71 In addition, a series of advanced mitigation improvements are to be committed to as part of the site preparation Section 106 Agreement. Whilst the site preparation works themselves will not generate substantial traffic, the opportunity has been taken to secure improvements to the local road network so that those improvements would be in place in time to reduce the impacts of the DCO project when it commences. Those commitments are to include:

- identification of suitable routes for HGV vehicles and the installation of a camera based monitoring system to ensure that those routes are adhered to;
- a series of traffic management improvements and mitigation schemes in Cannington and along the C182;
- junction improvements in Bridgwater and on the A39;
- the establishment of a Transport Steering Group and the commitment to a Travel Plan, as well as a **Traffic Incident Management Plan**; and
- condition and structural surveys of highways, together with commitments to any appropriate restoration.

B.3.72 As part of the DCO Section 106 Agreement, traffic monitoring, the Travel Plan, the Transport Steering Group etc are to be maintained and funded. In addition, a series of highway improvements are proposed on routes between the freight management facilities and Cannington (see earlier para. 7.4). EDF Energy is also committing to contribute funds towards pedestrian, cycle and safety improvements in Bridgwater.

B.3.73 In addition, the DCO itself proposes the construction of the Cannington Bypass. A schedule of proposals is attached to Appendix 15. The total cost of these works is estimated at £13,850,000.

xv. Other Commitments

B.3.74 In addition to the principal headings set out above, the analysis undertaken in preparation of the DCO application has identified a number of appropriate obligations including the following:

- a contribution of £236,000 towards the Bridgwater Strategic Flood Defence Tariff, which accumulates funds from all consented development in Bridgwater towards long term strategic flood defences;
- a series of detailed obligations are proposed at Combwich in order to mitigate the loss of facilities to the local sailing club and to replace them with enhanced facilities such as slip ways, pontoons and moorings (see **Appendix 13**);
- a contribution of £500,000 will be made towards the implementation of the Cannington Flood Alleviation Channel;
- EDF Energy will monitor sea levels and climate change against the long-term predictions set out in the Flood Risk Assessment throughout the operational life of Hinkley Point C. In the event that sea levels exceed a level to be defined in the Section 106 agreement, EDF Energy will notify the owners of properties who would be affected by a tidal breach or overtopping event in the Wick Moor flood cell and offer to enter into an agreement with those property owners in which it would agree to contribute to the reasonable cost of any repairs necessitated by an actual tidal breach or overtopping event. (The magnitude of impact of such a tidal breach or overtopping event on the affected properties is likely to be increased as a result of the provision of the construction platforms for Hinkley Point C and the proposed land raising in the Holford Stream valley.) The amount of EDF Energy's contribution to the costs of repairs would be proportionate to that part of the flood level caused as a result of Hinkley Point C; and
- proposals for noise insulation at Combwich in the immediate vicinity of the wharf and at Cannington to mitigate the impact of early years construction traffic prior to the completion of the Cannington Bypass.

xvi. Conclusion

B.3.75 The paragraphs above have explained the approach taken to limit, reduce and mitigate the likely significant impacts arising from the Hinkley Point C project against a series of topic headings. They have also explained the relationship between the proposed DCO obligations and those planning obligations already committed as part of the proposed Site Preparation Section 106 Agreement.

B.3.76 In preparing this DCO submission, a systematic and comprehensive approach has been taken to address all potential impacts of the development, to limit them where possible and to mitigate them where significant residual impacts remain. In addition, the opportunity has been taken to propose commitments in the Section 106 Agreement to a series of positive / beneficial measures (such as the commitments to Economic Development, Education and to Skills and Training, as well as Tourism) which are not principally designed to mitigate impacts but which are appropriate to secure EDF Energy's Vision for the HPC project. The IPC will need to decide what weight to attach to those positive commitments, which effectively form part of the HPC project.

B.3.77 The approach taken to mitigation is based on the policy approach set out in NPS EN-1 and has been worked up in an exemplary fashion based upon: a) detailed engagement with local stakeholders which has created a strong understanding of local issues and b) the outcome of all necessary assessments and a detailed approach to avoiding, limiting, assessing and then mitigating likely significant impacts.

b) Relevant Guidance: Requirements

B.3.78 NPS EN-1 provides guidance to the IPC about the approach which should be taken to requirements, as follows:

> *"4.1.7 The IPC should only impose requirements in relation to a development consent that are necessary, relevant to planning, relevant to the development to be consented, enforceable, precise and reasonable in all other respects. The IPC should take into account the guidance in Circular 11/95, as revised, on "The Use of Conditions in Planning Permissions" or any successor to it"*

B.3.79 These principles have guided EDF Energy's approach to the project requirements.

c) Proposed DCO Requirements

B.3.80 A schedule of requirements forms part of the draft DCO. It sets out a systematic framework of control to ensure that the project is designed, constructed and operated in accordance with the principles set out in the DCO application documents and that its effects are consistent with those assessed in the **Environmental Statement**.
