[This page is intentionally left blank]

APPENDIX 2A: SITE DRAINAGE STRATEGY

2A.1 Introduction

2A.1.1 EDF Energy is proposing to build two new nuclear reactors, known collectively as Hinkley Point C. This report considers drainage issues relating to the development of the site at all stages through the construction phase to commissioning, future operation and ultimate decommissioning.

2A.1.2 It identifies:

- the key regulatory stakeholders who have been consulted to date, approved elements of Site Preparation Works and who will need to consent new future drainage measures;
- the level of protection required against flood risk at various stages of development;
- measures that will be adopted to ensure that required level of flood risk criteria can be achieved;
- measures that will be adopted to ensure current water quality standards will be maintained in the water environment; and
- critically, how acceptable standards of site drainage (surface and foul) will continue to operate through the various stages of site development up to permanent operational function.

2A.1.3 Details of required conceptual drainage provision are provided. However whilst location of drainage features such as outfall discharge points and water management zones are identified, precise arrangement and sizing of structures cannot in all cases be defined in detail. Reservation of such detail to appropriate Development Consent Order (DCO) Requirements is proposed.

2A.1.4 The report covers the drainage within the HPC development site area and does not cover associated development outside of this area. However the impact of works within the site on flood risk to the immediate surrounding area is identified.

2A.2 Existing Site Drainage Features and Key Development Impacts

2A.2.1 The development site currently drains to one of three catchments, these being:

- Hinkley Point C drainage ditch network;
- Holford Stream; and
- Bum Brook.

2A.2.2 The extent of these catchments is shown in **Figure A.1.1**.

2A.2.3 The relationship of these catchments with other defined watercourses and hydrological salient features is shown in **Figure A.1.2**.

2A.2.4 The Bum Brook runs adjacent to the southern boundary of the HPC development site. There will be no site preparation earthworks undertaken within proximity to Bum Brook which could impact on flood risk or water quality. However permanent works include the construction of an emergency road which provides an alternative vehicular access to the Hinkley Point C site in the event that the C182 road is impassable due to extreme rainfall or overtopping/breach of coastal defences.

2A.2.5 The emergency road will include a bridge over the Bum Brook and a crossing of its flood plain. An indicative bridge crossing has been proposed and its impact assessed as part of the DCO Flood Risk Assessment (FRA). The modelling assessment confirms that the indicative bridge crossing of Bum Brook would not give rise to significant increase of water levels and flood risk frequency. The bridge would not affect upstream 3rd party receptors. However the extent of any increase of water levels will be more accurately determined as part of future detailed design. Holford Stream will be affected as a result of construction of the development because it will be necessary to infill the valley within which the stream is located. The EA has endorsed the findings of the Holford Stream Culverting Justification report provided by EDF Energy. The existing open stream will be replaced by a culvert within the site boundary.

2A.2.6 The culvert capacity is well in excess of that required to pass flows generated from the 59Ha catchment upstream of the development site.

2A.2.7 The majority of Hinkley Point C drainage ditch catchment is located within the development site. As a result the ditch necessary to make provision for the draining of the small 243,000m^2 extent of network will be largely abandoned being replaced by a more formal drainage infrastructure. It will be nice catchment, to the west, which will in future be located outside the boundary of the completed development. This will be provided with a headwall and outfall pipe which will connect to the temporary and permanent HPC internal drainage system.

2A.3 Regulatory Stakeholders and Consultation Summary

2A.3.1 The direct or deemed consent of a number of regulatory stakeholders will be required to enable development to proceed.

2A.3.2 Hinkley Point C development is classed as a nationally significant infrastructure project (NSIP). Consequently a Development Consent Order (DCO) application will be submitted to the Infrastructure Planning Commission. It is expected that an approved DCO would apply conditions (requirements) with respect to drainage. The IPC standard condition relating to drainage is:

> *“No [stage of the] authorised development shall commence until [for that stage,] written details of the surface and foul water drainage system (including means of pollution control) have, after consultation with the relevant planning authority and the sewerage and drainage authority, been submitted to and approved by the Commission.*
>
> *The surface and foul water drainage system must be constructed in accordance with the approved details. (Model Provision, Schedule 4, 14)”.*

2A.3.3 Drainage details pursuant to the planning application permission for the Site Preparation works were approved on 28 July 2011, by West Somerset Council (WSC) following liaison with other regulatory stakeholders. Whilst the main site construction and operational details outlined herein will be determined by the IPC, all future drainage works require similar liaison with the same regulatory stakeholders identified below.

a) Drainage Authorities

2A.3.4 The Environment Agency (EA) is the primary regulator responsible for managing flood risk and pollution with regard to the water environment. It is responsible for permitting of discharges to watercourses. It manages directly watercourses designated as main river.

2A.3.5 The, commonly EA maintains a fluvial (river) flood map which shows the extent of land which would be flooded as a result of a 1% annual exceedance probability flood (1.0% AEP). This is a flood that has a 1% chance of being equaled or exceeded in any single yearreferred to as a 1in 100 year flood. The EA also maintains a tidal flood map which shows the extent of land which would be flooded as a result of a 0.5% annual exceedance probability tidal flood or coastal defense breach (0.5% AEP). This is a flood that has a 0.5% chance of being equaled or exceeded in any single year, commonly referred to as a 1in 200 year flood. This land forms Flood Zone 3a/b for the purpose of Planning Policy Statement 25 (PPS25) and Strategic Flood Risk Assessment.

2A.3.6 It is noted that whilst the EA flood map is used for identification of areas currently at risk of flooding, climate change is expected to increase the intensity of rainfall and increase the extent of area at risk of flooding and depth of flooding to existing at risk areas. The impact of climate change up to 2100 has been taken into account both in the associated Flood Risk Assessment and this Site Drainage Strategy. Decommissioning plans which form part of the DCO submission estimate that the decommissioning of the site would be achieved in 2100, approximately 20 years after the end of generation in 2080. At the end of this stage all buildings on the site will have been removed with the exception of the Interim Spent Fuel Store and any associated support facilities. The ISFS will continue to operate until a Geological Disposal Facility becomes available, currently estimated to be in 2128 and the spent fuel is able to be disposed of. Final decommissioning of the ISFS is planned to be completed by approximately 2136. The need for adaption of drainage arrangements for the ISFS can be addressed at an appropriate further time when the impact of climate change beyond 2100 is more certain.

2A.3.7 The EA Flood Map is shown in **Figure A.1.3**

2A.3.8 Internal Drainage Boards or in their absence the local district council have permissive powers to manage and maintain non main rivers located in their area. Where they choose not to undertake maintenance, the riparian owner (owner of the land in which the watercourse is located) is responsible for channel maintenance. The river Parrett as a main river is the responsibility of the EA. Non main rivers within its catchment including, Bum Brook and Holford Stream, within the development site are the permissive maintenance responsibility of the Parrett Internal Drainage Board (PIDB). PIDB require to be consulted on any issues which may impact on the watercourse drainage network such as culverting the Holford Stream or constructing the

Bum Brook bridge. EA require to undertake a flood risk overview to ensure that such structures are hydraulically adequate.

2A.3.9 West Somerset Council (WSC) is a land drainage authority with powers to regulate activities affecting non main rivers, within its boundaries, which are not maintained by an Internal Drainage Board. The local Hinkley Point Drainage Ditch catchment is outside the PIDB boundary and thus the regulatory responsibility of the council.

2A.3.10 At present both Parrett Internal Drainage Board and West Somerset Council would expect to be consulted regarding development affecting watercourses in the Hinkley Point area. Both would seek in conjunction with the Environment Agency to ensure that any development is compliant with PPS25 both in terms of location, surface water management and mitigation of flood risk.

2A.3.11 The interests of the drainage authorities will be safeguarded both directly and indirectly. In addition to flood risk assessment of proposals which are physically located within or adjacent to a watercourse, the EA also have primary responsibility for water quality impacts. They will require to consent any discharge to controlled waters (effectively any existing watercourse). The Council will consult with the drainage authorities in respect of any discharge of conditions relating to drainage matters.

b) Sewerage Authority

2A.3.12 The sewerage authority is Wessex Water. Wessex Water does not have any sewerage infrastructure within the development site or which could be affected by the development. It is not proposed that Wessex Water be requested to adopt either site drainage or the sewage treatment works.

2A.3.13 As a result whilst they will have to opportunity to comment on the DCO, Wessex Water drainage and waste water treatment interests will not be affected and they will not provide future services. It is considered unlikely that they will wish to express interest or want to influence drainage of the development.

c) Local Planning Authority

2A.3.14 The planning authority is West Somerset Council (WSC). They are responsible for considering any planning application and subject to its compliance with local, regional and national policies grant planning consent.

2A.3.15 Conditions are normally attached to planning consents. These are in place to protect the interests of both the planning authority and other regulators. Thus drainage conditions will protect the interests of the EA and PIDB. They will only be discharged following consultation with these regulators.

2A.3.16 In respect of the DCO, the IPC will have responsibility for granting of consent. However WSC have a remit to provide a Local Impact Report (in addition to advising the IPC as to the adequacy of consultation) which will consider the local impacts of the development with regard to both the NPS, existing Development Plan policies, and other material considerations. They may also deal with applications to discharge DCO requirements.

d) Office of Nuclear Regulation

2A.3.17 ONR require a safety case to be made for any nuclear plant, under the conditions attached to the nuclear site license. The safety case addresses such issues as flood risk due to extreme rainfall or other causes. The required level of protection to be provided at Hinkley Point C for safety case is protection against flood hazards arising from a 0.01% AEP commonly referred to as a 1 in 10,000 year event.

e) Infrastructure Planning Commission Scoping Opinion

2A.3.18 As with the normal planning process followed by local planning authorities, the IPC require the provision of an Environmental Statement in support of a DCO submission. EDF Energy submitted an Environmental Impact Assessment Scoping Report seeking guidance from IPC in January 2010. Following a period of consultation with regulatory bodies and interested parties, the IPC issued a Scoping Opinion in April 2010. This Opinion indicated what issues the IPC would expect to addressed in the ES and FRA to be submitted with the DCO application. This scoping opinion included responses obtained from interested parties.

2A.3.19 Clear concerns regarding potential adverse drainage impact and flood risk, resultant on the implementation of the Site Preparation Works were registered by stakeholders including:

- The Environment Agency.
- Parrett Internal Drainage Board.
- West Somerset Council.
- Sedgemoor District Council.
- Stogursey Parish Council.
- Stringston Parish Council.

f) Summary

2A.3.20 The development of Hinkley Point C will be progressed in several key stages, including initial site preparation works, temporary and permanent construction works, final commissioning and operation. Each stage will require input to drainage design by both designers and contractors, in many cases yet to be appointed. There will also be a requirement to ensure that this Drainage Strategy aligns with other approved strategies relating to Hinkley Point C site development. In order to ensure that effective coordination takes place and that all work is compliant with the requirements of regulatory stakeholders, EDF Energy will take responsibility for direct liaison with regulators to negotiate discharge of planning conditions and obtaining the necessary consents/licenses.

2A.4 Flood Risk Assessment

a) PPS25 Compliance and Sequential Test

2A.4.2 The principle of PPS25 is to seek to ensure that development is directed to areas at lowest risk of flooding, defined as Flood Zone 1, resulting in an average 1,000 year protection against fluvial or tidal flooding events. Where due to lack of land availability or nature of activity, Flood Zone 1 land is unavailable or unsuitable, development may be permitted in Flood Zone 2, giving an average protection against fluvial or tidal flooding events of between 100 and 1,000 years.

2A.4.3 Development in Flood Zone 3 which has less than 100 year average protection against flooding from fluvial and tidal events and may be functional flood plain is permitted only in exceptional circumstances and application of the sequential test. This takes into account the nature of development and its vulnerability.

2A.4.4 Development at Hinkley Point C will take place in 2 stages; Site Preparation Works (which cover the whole of the development site), pursuant to planning permission granted by WSC and associated conditions, followed by permanent drainage and site infrastructure (pursuant to grant of DCO). In considering the Site Preparation Works planning application the Council have applied the tests set out in PPS25, considering the location of the site to identified Flood Zones (notably if within Flood Zone 2 or 3).

2A.4.5 As shown in **Figure A.1.3** the area of Holford Stream which is to be infilled and culverted is located in Flood Zone 3. The area directly next to the coast where a foreshore drainage outfall structure is to be constructed is also in Flood Zone 3. In accordance with PPS25 Table D.2, Annex D these development works are classed as Water Compatible thus being appropriate.

2A.4.6 The remaining area of the Holford valley located in Flood Zone 3 being earthworks is classified as Less Vulnerable and hence also appropriate.

2A.4.7 As a result of their consideration of the SPW FRA, WSC have concluded that the Hinkley Point C proposed works are compliant with PPS25 Sequential Test and planning consent has been granted.

2A.4.8 Following on from the Site Preparation Works and the obtaining of DCO from the IPC, development of permanent infrastructure and drainage will commence. The area of power station construction works is known as Built Development Area East and West. The majority of the development will take place in Flood Zone 1. A small area of development consisting of sea wall construction will take place in Flood Zone 3. However the Strategic Siting Assessment 2009 has stated that the Sequential Test for the Hinkley Point C Power Station Development is passed.

2A.4.9 As a result of the above considerations the location of all proposed development is demonstrated to be appropriate and siting of the Site Preparation Works and Hinkley Point C Development are compliant with PPS25.

b) Environmental Impact Assessment and Flood Risk Assessment

2A.4.10 As part of the planning application for the Site Preparation Works an Environmental Impact Assessment (EIA) was undertaken, results of which are reported in the Environmental Statement November 2010. In parallel a Flood Risk Assessment (FRA) was undertaken. Results of the FRA in part informed the EIA.

2A.4.11 The FRA conclusions were accepted by the EA who subsequently gave advice and agreed parameters to be used in the subsequent FRA undertaken to support the application for DCO for Hinkley Point C. This DCO FRA builds on the work undertaken for the previous FRA. By using updated surveys, tidal boundaries provided by the EA and other EA agreed refinements; it provides greater accuracy in predicting present day base conditions.

2A.4.12 The FRA model was amended to include Bum Brook emergency crossing and bridge, the Holford Stream culvert and associated structures Water Management Zones 4 and 5.

2A.4.13 The model has been run with a 2017 baseline and with an allowance for climate change at 2100, when with the exception of the ISFS and associated support structures, decommissioning of the development site will be complete. An assessment of drainage adaption requirements for these remaining structures will be undertaken at a time when climate change impacts beyond 2100 and up to 2140 become more certain.

c) Potential Flood Risk Impact of Proposed Development on Surrounding Areas

2A.4.14 By comparing the present day situation and the development models the effect of development has been confirmed. The FRA demonstrates that the local authority's expressed concerns regarding flooding are adequately addressed.

2A.4.15 The element of development work which has greatest potential for adversely impacting on current level of protection against flooding is the infilling of the Holford Stream valley and its substitution with a culvert. The valley currently provides storage volume during fluvial flooding events. It also provides storage volume in the event of overtopping or breach of sea defences in the Stolford area.

2A.4.16 The DCO FRA confirms the previous FRA conclusions that due to the removal of storage volume which results from infilling of the Holford Stream valley and creation of the construction platform some increase in flood depth is predicted in the Holford Stream catchment. This results from the combination of a low probability tidal surge together with a breach of the coastal flood defences. However as a result of attenuation of flow through attenuation and associated SuDS there is a reduction in fluvial flood risk.

2A.4.17 The Bum Brook, Bayleys Brook and Stogursey Brook catchments to the south are unaffected thus implementation of the Site Preparation Work and full development will create no adverse change in level of flood protection currently provided in these areas.

2A.4.18 Further refinements to the overtopping calculations and flood modelling as part of the DCO FRA has found that whilst the defences immediately east of Hinkley Point limit overtopping, those further east of Stolford still result in substantial volumes entering the Wick Moor flood cell. Under climate change scenarios this overtopping crosses the Stolford Peninsula and due to the infilling of the valley can lead to raised flood levels in the Wick Moor Flood Cell.

2A.4.19 The Holford Stream catchment locations affected are residential properties in the Stolford area and the C182 road crossing of the Holford valley. The previously predicted flood risk to the existing Hinkley Point sewage treatment works is removed for the 2017 completed development situation. Although flooding is predicted as a result of climate change by 2100, it is unlikely that the sewage treatment works will remain in use by that time.

2A.4.20 The Holford Stream culvert has been sized so as to pass fluvial flows under the platform. Security screens prevent access into the culvert and will be designed and maintained in accordance with best practice guidance. As a result the FRA has concluded that increased flood risk impacts due to blockage are negligible.

2A.4.21 With respect to predicted longer term increased flood risk at Stolford, EDF Energy will seek discussions with the EA based on the FRA findings to agree on appropriate mitigation against flood risk over the life of the Hinkley Point C development. However since any mitigation may only be required in the longer term and expected to be applicable at distance from the Hinkley Point C development site, further consideration is outside the scope of the Site Drainage Strategy.

2A.4.22 Provision of flood protection/resilience works to the sewage treatment works can be considered at a later date if they remain in longer term use such that as a result of climate change they become at risk.

2A.4.23 No mitigation of flood risk at the C182 road crossing of Holford Stream valley is proposed. Alternative access will be provided to Hinkley Point, initially by use of Site Preparation Works haul roads and on completion by use of the Visitor Access Road or Emergency Road via a bridge over the Bum Brook.

2A.4.24 The construction of the power station also results in the need to divert the Hinkley Point C ditch and the interception of other minor watercourses at the site boundary. The FRA concluded that as drainage will be designed and maintained through construction operation and decommissioning of the power station this will ensure no increase in residual flood risk as a result of the development. Suitably sized pipes will be provided to allow watercourses to discharge under the perimeter fence.

2A.4.25 The change in land use will result in rates of runoff being increased. The SPW FRA calculated the likely flow rates and storage volumes required in WMZs to control the rate of runoff into watercourses, during construction, to greenfield rates. Within the future power station site the Hinkley Point C drainage ditch will be abandoned during the course of construction. The watercourse will be replaced with a temporary drainage system which will discharge to the Bristol Channel via the Foreshore Outfall. The EA has confirmed that once discharge direct to the Bristol Channel is in place attenuation of flow through WMZs 1, 2 and 3 to control rate of flow to greenfield rates is not required. WMZs have an alternative function in treating runoff and other flows so that discharges are compliant with Environmental Permitting. WMZs 1, 2 and 3 are required for this purpose and will have the incidental effect of attenuating flows. The extent of this attenuation will be determined by the design of the WMZs. Upon completion of construction and commissioning of the power station, operational drainage discharge point will transfer from the Foreshore Outfall to the Cooling Water Outfall Tunnel and WMZs 1, 2 and 3 abandoned removing any attenuation. The EA have confirmed that operational drainage discharged via the Cooling Water Outfall Tunnel does not need to be attenuated.

2A.4.26 Hinkley Point C development does include for the provision of an Emergency Road which will include a bridge and associated crossing of the Bum Brook at Shurton. The DCO FRA demonstrates that the bridge arrangement as modelled does not have any impact on upstream 3rd party receptors. The bridge will be subject to detailed design at a later stage and will be subject to EA/PIDB approval.

2A.5 Drainage Strategy - Overview

a) Governing Principles

2A.5.2 The high level purpose of the Drainage Strategy is to ensure that throughout the course of development, from Site Preparation Work, Hinkley Point C power station construction, subsequent operation to decommissioning, appropriate systems of drainage are provided, maintained and operated. It sets out the required performance standards for levels of flood protection and avoidance of pollution of the water environment which is to be achieved at all stages.

2A.5.3 A regulator approved detailed strategy for Site Preparation Work is already available together with a concept strategy for Hinkley Point C construction. It is intended that the technical detail of this Drainage Strategy will evolve with design, through co-ordination with other strategies and as further regulatory consents are obtained. Consequently, whilst there is a necessary reliance upon reserving details to DCO requirements as appropriate, it is important that this strategy sets the conceptual framework for a site drainage infrastructure that meets regulatory requirements on an ‘in principle’ basis and provides reassurance, for both regulator and applicant, that such compliance will be maintained throughout the development process.

2A.5.4 During construction the level of protection agreed with stakeholders is that drainage systems will be required to discharge runoff from a 30 year return period rainfall event without flooding. Surface water discharge rates into existing water bodies (Bum Brook, Holford Stream & Hinkley Point C drainage ditch) are to be maintained at existing greenfield (Q_{bar}) runoff. This will be achieved by routing all flow through Water Management Zones (WMZs). However once the Foreshore Outfall is constructed Hinkley C drainage ditch can be abandoned. At this stage the Built Development Area will discharge directly into the Bristol Channel. The EA has confirmed that at this stage attenuation of flow in WMZs 1, 2 and 3 will not be required.

2A.5.5 Water Management Zones will also be used to ensure that potential pollutants which result from construction activity, however well managed, for example sediment, turbidity and hydrocarbons can be contained so that existing water quality within Bum Brook, Holford Stream and Hinkley Point C drainage ditch/Foreshore Outfall is maintained.

2A.5.6 The permanent drainage works will be required to provide a level of protection against flooding for that part of the site comprising Build Development Areas East and West, access roads and car parks such that there will be no surface flooding during a 100 year return period rainfall event (1.0%AEP).

2A.5.7 In addition to the normal drainage related standards, the Strategy will:

- set out how compliance with Nuclear Safety Case 10,000 year return period (0.01%AEP) protection against internal flooding of safety related buildings will be achieved;
- address the impact of exceedance rainfall events on the drainage network and development site;
- identify the need for mitigation measures;

- address requirements for provision of temporary and permanent foul water drainage, sewage treatment and discharge of final effluent; and
- be used as a plan to manage a transition/evolution of drainage systems from current basic provision through temporary works to permanent drainage provision and ultimate decommissioning.

2A.5.8 It is intended that the Drainage Strategy will ensure compliance with performance standards formally set as conditions by regulatory stakeholders, planning policies and national guidance such as Pollution Prevention Guidelines issued by the Environment Agency. This will allow regulators to issue consents and discharge planning conditions such that construction may proceed.

b) High level Indicative Programme

2A.5.9 An indicative high level programme is shown in **Table A1.1**. The programme identifies stages of development being:

- Enabling Works.
- Site Preparation Works design, consents and construction of temporary drainage.
- Operational Works design, consents, construction and commissioning of permanent drainage.
- Transitional Drainage from temporary arrangements to operational drainage.
- Decommissioning Works.

2A.5.10 Plans showing stages of development with time are shown in phasing plans as presented in the Construction Method Statement. The operational site will be designed and constructed in 4 phases. The areas covered in each phase are shown in **Figure A.1.4**.

2A.5.11 Phase 1 covers design of the general layout and siting of buildings, roads and infrastructure. It shows the maximum size of buildings. These may be subject to reduction at detailed design stage in Phases 2, 3 and 4.

2A.5.12 Phase 2 shown yellow covers detailed design of the Ancillary Building Zone. It is currently anticipated that main construction will take place between 2013 and 2017. However construction of the access connection with the C182 road may commence in 2012.

2A.5.13 Phase 3 shown green covers detailed design of Unit 1. It is currently anticipated that this will be constructed between 2013 and 2017 with commissioning commencing in 2018. The permanent Sewage Treatment Plant (PSTP) and Attenuation Pond surface water treatment facility will be constructed as part of Phase 3.

2A.5.14 Since Phase 2 works and parts of Phase 3 will be complete and generating foul and surface water discharges before completion and commissioning of the treatment facilities it follows that the temporary treatment facilities provided by WMZs 1, 2 and 3 will need to remain in use whilst draining permanent drainage facilities. Similarly the Foreshore Outfall structure will need to remain in use to dispose of treated foul and surface water flows until the Cooling Water Discharge Tunnel is commissioned and in use.

Drainage and restoration of land drainage

2A.5.15 Phase 4 shown blue covers detailed design of Unit 2. It is currently anticipated that this will be constructed between 2014 and 2020 with commissioning in 2020. Catchment 10 to the west of the Built Development Area drains into the Phase 4 area and its flows must be accommodated at all times, currently via the existing Hinkley Point C drainage ditch, subsequently through the temporary drainage system and ultimately via the permanent drainage system before being reinstated as a watercourse upon decommissioning.

2A.5.16 Whilst the indicative construction dates quoted may be subject to some variation the sequence of phasing is fixed. The above examples demonstrate the interdependence of temporary and permanent operational drainage systems which the Drainage Strategy addresses.

c) Site Preparation Works Drainage Impacts

2A.5.17 The development as approved by WSC under planning consent consists of:

- general site clearance;
- erection of site boundary fences which cut across existing ditches;
- earthworks consisting of topsoil stripping and storage, deep excavation, site levelling for the creation of construction platforms and backfilling;
- dewatering of deep excavations;
- drainage works consisting of modification of existing drainage network, diversion and culverting of the Holford Stream, construction of coastal outfall, creation of water management zones; and
- stockpiling of excavated materials.

2A.5.18 In order to undertake the work there will be a need for the provision of site services and facilities which will include site establishment works (compounds, welfare facilities, haul roads, site access, vehicle parking, utility services) and provision and operation of construction plant and machinery (concrete batching, refuelling, aggregate crushing, wheel and plant washing).

2A.5.19 The general site layout during the preparation works is shown in the Construction Method Statement. These works will have potential impacts on drainage and hydrology in a number of respects including:

- conversion of greenfield to more impermeable surface with increased volume of overland flow;
- increased peak rate of flow due to reduced time of concentration;
- increased sediment transport loading on watercourses, increased risk of flooding and pollution;
- ground water pollution;
- ground water elevation changes due to dewatering and potential reduction in Holford Stream water levels;
- obstruction of existing ditches and watercourses by erection of site boundary fences;

- potential effects of operation of plant and construction activity; and
- disposal of treated final effluent to watercourse.

2A.5.20 The Drainage Strategy seeks to eliminate or mitigate increased flood risk, water quality and hydrological impacts through the design and location of structures and the provision of Water Management Zones.

d) Site Boundary Fencing

2A.5.21 There will be a requirement to provide a boundary fence to secure the site prior to full commencement of site preparation works. A total of nine locations have been identified where the fence will cross local ditches or watercourses. In order to prevent flow restrictions and increased flood risk each crossing will be culverted with an appropriately sized pipe. For pipes exceeding 300mm diameter security grilles will be provided to prevent unauthorised access.

2A.5.22 The culverting proposals have been submitted to and approved by the EA.

2A.5.23 The culverting proposals located within the Holford Stream catchment have been submitted to and approved by PIDB.

2A.5.24 The culverting proposals located within the HPC Drainage Ditch have been submitted to WSC who have made no formal response.

e) Drainage Catchments and Water Management Zones

2A.5.25 Initial site preparation works will take place within the catchment of the Hinkley Point C drainage ditch. Area of work and approximate location of Early Water Management Zones (EWMZ) 1 & 2 is shown in **Figure A.1.5**. The FRA estimated required storage volume required to contain runoff flows from a 30 year rainfall event whilst limiting outflow to greenfield runoff is estimated to be of the order of 29,500m^3. Following the initial site preparation works, main earthworks and construction will commence. For the purpose of drainage and water management the whole of the development site and upstream Hinkley Point C drainage ditch/Holford Stream catchments have been divided up into sub catchments and Water Management Zones (WMZ).

2A.5.26 With the exception of sub catchment 11 which drains to the Holford Stream upstream of the development site, all sub catchments are required to pass through a WMZ in order to achieve outflow to the required greenfield runoff whilst storing runoff from a 30 year rainfall (3.3%AEP) event without flooding. The WMZs are also required to control pollution so that existing water quality in the Hinkley Point C ditch outfall and Holford Stream can be maintained.

2A.5.27 The arrangement of sub catchments and WMZs developed by EDF Energy and approved in principle by the EA are shown in **Figure A.1.6.** The Site Preparation Works contractor will provide a suitable design for drainage systems and WMZs in the approximate positions shown. The designs shall ensure compliance with flood protection standards agreed by the EA and EDF Energy. The designs shall also comply with the terms of Environmental Permits issued by the EA which relate to water quality.

2A.5.28 Sub catchment areas 12 and 14 which naturally drain to the Bum Brook will not be affected by Site Preparation Works.

2A.5.29 Water quality standards are based on baseline conditions for water quality in the Hinkley Point C ditch and the Holford Stream. They are based on compliance with legislation, primarily the Water Framework Directive (WFD) and Freshwater Fish Directive.

2A.5.30 The SPW EIA concludes that freshwater quality status of Holford Stream is high. The freshwater quality of the Hinkley Point C drainage ditch is low. Hinkley Point C drainage ditch was found to have variable conditions with high suspended solids content and to dry out for extended periods. Given the observed differences in water quality and the Hinkley Point C ditch discharge direct to foreshore the Environmental Permit requirements will not be the same for both watercourses.

2A.5.31 For the purpose of Drainage Strategy it is also convenient to consider areas of work by site preparation, temporary, permanent and activity in order that drainage issues and impacts can be addressed.

2A.5.32 The areas and stages of development relating to surface water drainage are:

- Site Preparation Works Built Development Areas East & West – covered initially by EWMZs 1 & 2, subsequently by WMZs 1, 2 and 3.
- Site Preparation Works Southern Construction Area – covered by WMZs 4 & 5.
- Holford Stream culverting and infill of valley.
- Hinkley Point C coastal outfall.
- Permanent works Built Development Areas East & West.
- Emergency Road.

2A.5.33 The provision of temporary and permanent foul water network and sewage treatment is considered as a separate element.

f) Built Development Area

2A.5.34 Initial Site Preparation Works consisting of surface clearance will commence at the same time as that of the Southern Construction Area. It will be necessary to retain a drainage facility to pass any flows from land to the west of the development site (catchment 10), through the site and discharge to the foreshore.

Initial use of Hinkley Point C Drainage Ditch

2A.5.35 During this initial phase and pending construction and commissioning of a new Foreshore Outfall structure, all flows will continue to pass through the existing Hinkley Point C drainage ditch discharge point to the foreshore. Discharge will be routed via EWMZ1. The estimated required size for EWMZ1 is 29,500m^3. However this is for guidance and the contractor will need to undertake their own assessment.

2A.5.36 The appointed contractor will be responsible for providing a design for layout of the WMZ. They will be required to provide design details, method statements and other required documents including an Accident and Incident Response Plan, Water and Sediment Management Plan which demonstrate how their construction and operation will be undertaken in such a way as to comply with the Drainage Strategy and water quality/greenfield runoff standards agreed with the EA confirming in particular:

- how overland flow will be removed so as not to degrade the platform surface;
- how overland flow will be removed so as to ensure no surface flooding or ponding of water;
- how runoff will be directed to the WMZ;
- that the WMZ will have capacity to contain run off from a 30 year (3.3%AEP) rainfall event whilst allowing greenfield runoff discharge to Hinkley Point C ditch;
- how exceedance rainfall events will be managed without risk to the WMZ structure and other construction works in progress;
- how silt will be removed prior to discharge into the Hinkley Point C ditch;
- how hydrocarbons and other pollutants can be contained within the WMZ; and
- what arrangements are in place to shut down the outfall to Hinkley Point C ditch in an emergency.

2A.5.37 It is anticipated that as work adjacent to the foreshore proceeds it may be necessary to move location of EWMZ1 to a new location EWMZ2. Alternatively the contractor may create EWMZ2 and divert the piped flows from the east such that EWMZ1 is not required.

Temporary Drainage Network Foreshore Outfall Structure

2A.5.38 Construction of drainage for Site Preparation Works will commence with the construction of the Foreshore Outfall structure. The location for the outfall has been selected to ensure least environmental impact following marine ecology assessment and approved by the EA in principle.

2A.5.39 The invert level of the outfall pipe is set above highest astronomical tide level. Energy of water which is estimated to discharge at a peak rate of 13.5m3/s during the 30 year rainfall event will be dissipated by provision of baffle blocks on the base of the outlet bay. The invert level of the outfall pipe is set above highest astronomical tide level at a level of 7.5mAOD. As part of the SPW FRA, calculations were undertaken to confirm that all of the Built Development Areas and the Hinkley Point C drainage ditch to the west could be drained by gravity to an outfall set at this level. Flow rate at the outfall has been estimated to be at a peak rate of 13.5m3/s during the 30 year (3.3%AEP) rainfall event. This does not take account of any incidental attenuation produced by WMZs 1, 2 and 3. The calculations assume the outfall downstream of the collector drain will be 2100mm diameter set at a gradient of 1/166. The formal design of the outfall and temporary works drainage will be undertaken by the site preparation works contractor and demonstrate compliance with flood risk criteria. There will be a requirement for energy dissipation provision at the outfall headwall.

2A.5.40 The outfall structure will need to be located such that it does not conflict with the construction of the permanent sea wall. Arrangement shall be made to ensure safe access for pedestrians along the foreshore. It is anticipated that such access will be to the rear of the outfall structure.

2A.5.41 The outfall structure and pipe shall be capable of removal to a point within the permanent sea wall such that the seaward face of the sea wall can be reinstated flush with the adjacent profile.

g) Temporary Drainage Network Collector Drain and Spine Drains

2A.5.42 Collector drain will be provided to connect from the Foreshore Outfall to a manhole at the rear of the proposed sea wall. It will then run parallel to the foreshore and clear of the sea wall construction area. It will provide an outfall for 3 spine drains which will cross the site from south to north. The indicative position of these spine drains A, B and C are shown in **Figure A.1.6**.

2A.5.43 This basic drainage network will provide an outfall for conveyance of all surface water flows arising during site preparation and construction and will be required to remain in use until commissioning of the power station is sufficiently advanced that the permanent drainage systems can be used and the Cooling Water Outfall Tunnel is available to discharge treated surface water flows and final effluent. For this reason it is necessary to ensure that the line and level of the temporary drainage system will not conflict with proposed buildings, structures and other services.

2A.5.44 The drain provided at time of site strip and clearance which transfers any flows from land to the west of the development site (catchment 10) will need to be diverted into spine drain C.

Temporary Drainage Network Water Management Zones

2A.5.45 Each spine drain will discharge to the collector drain via a WMZ. Because WMZs 1, 2 and 3 will discharge to the foreshore rather than to watercourse the EA has accepted that attenuation to greenfield runoff is not required. The contractor will need to undertake their own assessment as to required size based on the requirement to comply with water quality and passing runoff from a 30 year (3.3%AEP) rainfall event.

2A.5.46 The contractor will also provide design calculations to show that the drains have suitable capacity to drain all surface water runoff derived at any stage in construction for a 30 year (3.3%AEP) rainfall event, without surface flooding. Details will also be required to demonstrate how exceedance rainfall event runoff will be conveyed overland so as not to flood excavations, damage the works or halt construction.

2A.5.47 Design criteria for the drains will be that applied to the permanent drains in order to provide an option for them to be incorporated into permanent works. If design of permanent drainage is completed prior to design of spine drains and routes/locations are capable of use for temporary spine drains then the contractor will be provided with the design and the spine drains will be treated as permanent.

Temporary Groundwater Dewatering

2A.5.48 Once the temporary drainage is complete and construction terraces have been constructed it will be necessary to undertake deep excavation for construction of the EPR reactor units. Platform level is 14mOD and foundation depth is approximately 3mOD. Geological and Hydrogeological review indicates that groundwater levels range from 6 to 10mOD. As a result it will be necessary to lower the groundwater levels to a sufficient depth that excavation and subsequent construction can take place in the dry.

2A.5.49 It is intended that dewatering be undertaken by the installation of deep wells. These would be installed in boreholes. Once working the dewatering system will draw down groundwater and any accumulation of surface water ponding in the base of the excavation. It has been estimated that total of 6,300m^3 groundwater will be removed in order that construction within the base of the excavation can be undertaken. Routine periodic pumping will be required to prevent groundwater build up.

2A.5.50 The design of deep wells and collector drains is the responsibility of the contractor. Based on site investigation and assessment of geological information a potential contractor has indicated that approximately 40 wells will be required and discharge rate during draw down will be in the range 60 – 140 l/s. Once a dry base of excavation has been achieved the deep wells will be operated as required to maintain reduced ground level.

2A.5.51 A drainage system will be installed around the perimeter of the deep excavation to intercept and remove and surface runoff so as to minimise surface water accumulation in the base. This will discharge to the spine drain system.

2A.5.52 Dewatering the deep excavation area will result in drawing down ground water levels in the surrounding strata. However it is not anticipated that the draw down will impact on base flow in the Holford Stream to the south.

2A.5.53 The groundwater dewatering network will be handed over to the permanent works contractor for use until the permanent groundwater galleries are commissioned.

2A.5.54 Temporary Foul Water Drainage and Sewage Treatment Temporary foul water drains and temporary sewage treatment plants (TSTP) are proposed for collection of domestic sewage, its treatment and disposal of final effluent. The proposed locations are shown in **Figure A.1.6**. Details of the foul drainage network and sewage loadings for treatment are to be determined. The TSTPs will require consents to discharge from the EA and UWWT final effluent sampling points will need to be provided.

2A.5.55 All TSTPs are located in sub catchment 1. Treated final effluent is shown to be connected into Main Spine Drain C for disposal. However this would pass final effluent through WMZ1 before discharge via the collector drain and outfall to the foreshore. The contractor may choose to provide a separate final effluent pipe bypassing WMZ1 and connecting direct to the collector drain.

h) Southern Construction Area

Holford Stream Culverting

2A.5.56 In order to provide room for construction of the permanent works in Built Development Areas East & West it is necessary to occupy area to the south both for stockpiling of excavated material, provision of compounds and support services. A direct consequence is the need for culverting of the Holford Stream to allow infilling of the valley and creation of construction platforms.

2A.5.57 The need for culverting has been accepted by the EA and an outline feasibility design has been agreed with the PIDB. The hydraulic performance of the culvert has been the subject of study as part of the FRA.

2A.5.58 There are two streams within the valley which enter the site from upstream. The crossing points have references CP5 and CP6. CP5 is at a higher level and will need to be diverted to the valley floor downstream of CP6.

2A.5.59 The culvert will extend over a distance of approximately 690m and will run parallel to the existing stream in the valley bottom. It is proposed to offset by a distance of approximately 50m to the north. This position has been selected in order to obtain better ground conditions to support the culvert. Following diversion of the higher level stream at CP5, it also has the benefit of providing separation from the remaining stream in the valley floor, minimising risk of disturbance or pollution.

2A.5.60 During construction of the culvert there will be a potential need to undertake dewatering of the excavation. Environmental Permits have been obtained which will allow discharge to the Holford Stream at 5 points along the length of the culvert. The appointed contractor will provide appropriate measures to ensure that water quality of discharge is compliant.

2A.5.61 Sufficient room is provided at either end of the culvert to construct inlet/outlet headwalls and divert, within the development site, the route of the stream via the culvert. The streams at CP5 and CP6 will be diverted into the inlet. The outlet from the culvert will discharge to the stream in the valley bottom which exits the site at CP8.

2A.5.62 The size of the culvert has been determined by access rather than hydraulic capacity considerations. Given the length of culvert and its confined space health & safety status, it is intended that routine inspection will be undertaken by driving through the culvert. Accordingly the culvert will be a minimum of 2.5m wide and 2.5m high or such larger size that is available as standard from box culvert manufacturers.

2A.5.63 Based on these dimensions and gradient the hydraulic capacity of the culvert will be $18m^3/s$. The 100 year (1.0%AEP) rainfall event runoff calculated for the FRA is $1.8m^3/s$. The velocity of flow for this discharge is 1.5m/s. However it is not intended that the culvert would be accessed in time of rainfall.

2A.5.64 Unauthorised access will be prevented by the installation of grilles at inlet and outlet headwalls. The inlet grille will also serve as a trash screen to prevent ingress of debris to the culvert. The area of the grille is such that full blockage of the culvert is extremely unlikely. In any event it will be subject to routine maintenance inspection and any accumulation of debris removed.

2A.5.65 Given the length of culvert three intermediate shafts are to be provided for ventilation purposes. It is not intended that these be used to access the culvert and no ladders or staging will be provided.

2A.5.66 In order to prevent elevated groundwater levels and avoid risk of floatation a land drainage system will be installed on either side of the culvert. The land drains will discharge through the culvert outlet headwall into the stream.

2A.5.67 The sections of watercourse forming the diversion into and out of the culvert will be protected against erosion. This will be in the form of in situ concrete or stone pitched bed and sides. In addition there will be a water cushion sump at outlet which will cause reduction in exit velocity of flow.

2A.5.68 In the event that DCO is not obtained then the culvert will be removed and the Holford Stream reinstated. In the event that DCO is granted then the EA have accepted that the culvert will remain as a permanent feature.

Infilling of Valley

2A.5.69 Once the culvert construction is complete, site strip and filling of the valley can commence. Finished levels for platforms will range from 17 to 23mOD relative to the current low point of 6mOD at Holford Stream. Maximum height of stockpiled topsoil for reuse will not exceed 32mOD.

2A.5.70 The platforms will tie into existing ground levels to the south and required levels for Built Development Areas East and West to the north.

2A.5.71 The contractor will be responsible for the design and provision of drainage systems to manage and control surface water runoff (pluvial flow). The contractor has indicated in Environmental Permit Supporting Information MS002 that a system of open drainage ditches will be provided. The ditches will intercept and route all flow to WMZs.

2A.5.72 The ditches will require adjustment as ground levels rise, until they reach required construction platform level. The ditches will be required to have capacity to discharge runoff from a 30 year (3.3%AEP) rainfall event without flooding of the site.

2A.5.73 The ditches will subsequently remove runoff from the stockpiles. A potential risk of acid rock runoff reducing pH to levels not compliant with Environmental Permitting has been identified. The contractor has indicated that measures to control acidic leachate will be provided at source prior to discharge into the ditches.

Haul Roads

2A.5.74 Haul roads will be located to the east and west edges of the platforms beyond which side slopes of variable width and gradient will be constructed to tie into existing ground levels.

2A.5.75 The haul roads will be constructed to current British Standards and Design Manual for Roads and Bridges (DMRB). Final surface finish will be compacted granular material. Surface water drainage will be required in order to ensure that the haul roads remain useable during and after rainfall events. This will be in the form of a surface crossfall and provision of a swale ditch to collect runoff. To the extent that runoff does not infiltrate into the ground it will be routed to the WMZs via the system of ditches used to drain the construction platform.

2A.5.76 Once completed, the haul roads will be available as an emergency access in the event that flooding of the C182 occurs during a major tidal surge/breach of coastal defence. The haul roads will tie into the C182 through the construction of a north east and south east roundabout. The south east roundabout will be of normal DMRB construction and include the provision of formal highway drainage.

The highway drainage will have capacity to remove runoff from a 30-year rainfall event without surface flooding.

Water Management Zones 4 and 5

2A.5.77 WMZ4 will be located to the east and south of Holford Stream. WMZ5 will be located at the base of the slope to the west.

2A.5.78 The appointed contractor will be responsible for providing a design for layout of the WMZ as described in paragraph A1.5.48 above. The appointed contractor will be responsible for providing a design for layout of the WMZ as described in paragraph A1.5.48 above. However guidance has been provided though both the SPW FRA and SPW Environmental Statement. The design must ensure that the flood risk and quality standards agreed by EDF Energy with the EA are met.

2A.5.79 The FRA estimated required size for the WMZ4 is 16,000m^3 and for WMZ5 8,000m^3. However, the contractor will need to undertake their own assessment as part of their design.

2A.5.80 The Site Preparation Works Environmental Statement provides an indicative description of what WMZs 4 and 5 are expected to comprise but this is not prescriptive.

2A.5.81 It is assumed that WMZ ponds would be no more than 3m deep with shallow side slopes for stability. They would be lined with MDPE sheeting which would be tied into the banks.

2A.5.82 They would have a formal outfall structure. Greenfield flow rate would be achieved by some form of throttle control on the outfall pipe.

2A.5.83 The WMZs would have a second high level overflow arrangement as it is necessary to ensure that overtopping of the WMZ will not result in breach and failure of the pond. Whilst the setting of an overflow level has not been formally specified within the Environmental Statement it is considered that it should be set at the predicted 100 year (1.0%AEP) FRA fluvial flood level to ensure that back up of flooding from the Holford Stream will not overtop the WMZ bund crest and wash out the WMZ contents. As a precaution the bund crest should be set with a freeboard level 300mm above the overflow. The surface finish of the overflow should be protected so as to avoid erosion during operation. It is also necessary to ensure that the WMZ water level should not reach overflow crest during the 100 year (1.0%AEP) event. Confirmation of exceedance event flow paths both to and from the WMZs is also required.

2A.5.84 Once completed, the haul roads will be available as an emergency access in the event that flooding of the C182 occurs during a major tidal surge/breach of coastal defence. The haul roads will tie into the C182 through the construction of a north east and south east roundabout. The south east roundabout will be of normal DMRB construction and include the provision of formal highway drainage. The highway drainage will have capacity to remove runoff from a 30-year rainfall event without surface flooding On Site Campus Drainage.

2A.5.85 The On-site campus will be constructed adjacent to the south east roundabout and require provision of surface water drainage connecting to WMZ4 to the north. This drainage system will also need to remove final effluent. The On-site campus will be constructed adjacent to the south east roundabout and require provision of surface water drainage. An indicative layout for a traditional piped drainage network is shown in the DCO FRA. The drainage network will be required to have capacity to remove runoff from a 30 year rainfall event without surface flooding. Provision for managing exceedance rainfall overland flow so as to mitigate risk of internal flooding is also required.

2A.5.86 A foul water drain will be provided to collect sewage and wastewater which will be treated in a temporary sewage treatment plant TSTP. The final effluent will need to comply with the requirements of the Environmental Permit. The final effluent pipe will discharge to the same outfall pipe as the surface water drain. All foul water infrastructure will be removed as part of decommissioning of the On-site campus.

2A.5.87 The common outfall pipe will discharge via a headwall to a ditch which will convey flows to WMZ4.

Groundwater and Land Drainage

2A.5.88 No significant dewatering of excavations is anticipated and since groundwater movements tend to be from the south, groundwater input to base flow in Bum Brook is not expected to be affected.

2A.5.89 Holford Stream catchment is closer to the area of dewatering within the Built Development Areas but from previous investigation there is a discontinuity in the Green Lane ridge area that should prevent lowering of groundwater levels which could affect stream base flow.

2A.5.90 The infilling of the valley may have some impact on groundwater migration and levels but land drains installed on either side of the Holford Stream culvert will allow any groundwater to discharge downstream of the culvert. Outflow from WMZs 4 and 5 will also contribute to base flow through attenuation of runoff.

2A.6 Operational Power Station Permanent Drainage Network in Built Development Areas

a) Site Layout Determinants

2A.6.2 The layout of the operational power station and its component parts has been set in Phase 1 design. Maximum required sizes of operational buildings were determined to provide footprints. Road networks have been superimposed on the layout to provide suitable access and all infrastructure including drainage networks will be generally located along the line of roads in order to maximize access for maintenance.

2A.6.3 The power station is provided with a number of permanent drainage systems comprising:

- surface water drainage;
- plant drainage;

- foul drainage; and
- groundwater drainage.

2A.6.4 Following appropriate treatment and monitoring, the ultimate discharge point of most of these systems is the main power station Cooling Water Outfall Tunnel which extends approximately 1.8km offshore in the Bristol Channel.

2A.6.5 Flow rate from the above sources will be small relative to the cooling water component which will have a flow rate in the order of $130m^3/s$. Surface water flow rate resulting from a 100 year (1.0%AEP) rainfall event would be in the range of 15 to $28m^3/s$ whilst the other components would not exceed $1m^3/s$.

2A.6.6 Sea wall groundwater drainage – through penetrations in the sea wall to the foreshore. The exceptions to the common cooling water outfall tunnel discharge point are:

- Cooling water forebay overflow – through penetrations in the sea wall to the foreshore.
- Sea wall groundwater drainage – through penetrations in the sea wall to the foreshore.
- Groundwater gallery – discharging to the forebay.

2A.6.7 In addition, for rainfall events of a lower frequency than the 100 year (1.0%AEP) design rainfall, run-off which cannot enter the surface water drainage network will be routed by overland flow to an open channel at the base of the slope which runs from the 14.0m platform to the rear of the coastal path. The channel will be drained through penetrations in the sea wall to the foreshore. In more extreme rainfall events, if the capacity of the channel is exceeded water levels will be controlled since there will be a flow path across the sea wall through the pedestrian and vehicle gaps in the crest of the wall.

2A.6.8 Consideration was given to permanent use of the Foreshore Outfall Structure through the sea wall for the discharges not routed through the Cooling Water Outfall Tunnel. However this has been discounted on grounds of security and operational risk. The sea wall will be constructed as a mass concrete structure and the penetrations will be in the form of pipes with diameter not exceeding 225mm. The pipes will not project forward of the sea wall profile. As a result the penetrations created by the pipes will not have any adverse effect on the sea wall flood protection performance.

2A.6.9 The layout of surface water drainage networks is determined by the need to drain impermeable roofs, roads and car parks discharging to the Attenuation Pond prior to combined discharge to the Surge Tank and Cooling Water Outfall Tunnel.

2A.6.10 The layout of foul drainage is determined by the location of buildings which generate foul sewage and the requirement to route all flows via the road network to the permanent sewage treatment works (PSTW).

b) Flood Risk Factors

2A.6.11 Drainage regulator required level of protection against flood risk is that the surface water drainage networks within the operational power station site have capacity to remove runoff resulting from a 100 year (1.0%AEP) rainfall event without surface flooding. The 100 year rainfall event intensity to be used for design is adjusted for predicted climate change up to 2100. Base rainfall and climatic change data has been determined by the Meteorological Office and is contained in their report "Extreme Precipitation Analysis at Hinkley Point.

2A.6.12 The worst case rainfall in terms of summer or winter profile and duration will be determined by drainage network simulation using the InfoWorks or similar acceptable computer modelling package.

2A.6.13 Safety Case required level of protection is that there must be no detrimental flooding as a result of a 10,000 year rainfall event. This is taken as meaning that there must be no risk of floodwater entering safety-related buildings. It is expected that such extreme rainfall will result in the engineered drainage networks being overwhelmed and superficial flooding of the site platforms. Protection will be achieved primarily through a combination of engineered falls of the site platform to direct the superficial floodwater away from critical buildings and raising the entrance thresholds for such buildings to above the assessed flood levels. However, other options will be reviewed at design stage.

c) Proposed Surface Water Networks

2A.6.14 In addition to providing sufficient protection against flooding it is also necessary to ensure that flows which will be disposed to sea in the Bristol Channel the cooling water outfall tunnel are of satisfactory quality.

2A.6.15 In order to ensure acceptable water quality, three separate drainage systems will be provided:

- roof drainage – EDF Energy designation SEO-EP (Roof);
- road and car park drainage – EDF Energy designation SEO-EP (Roads); and
- areas with high risk of hydrocarbon contamination – EDF Energy designation SEH.

2A.6.16 Drainage from roofs is considered to have no potential to be contaminated by hydrocarbons and hence can be disposed to sea without any form of treatment. Given the relative area of roof to be drained there is a benefit keeping roof water separate and reducing volume of rainwater flow which requires some form of treatment.

2A.6.17 Drainage from roads and car parks will have some level of contamination by hydrocarbons, to an extent variable and dependent on antecedent rainfall conditions. In general the initial runoff from surfaces will tend to be more polluting. As a result it is necessary that provision be made for the ability to treat runoff if required.

2A.6.18 The network SEH is provided to drain areas at high risk of pollution due to hydrocarbon pollution or major spillage incident. Areas which are expected to be connected to the network will include bunded oil, storage areas, transformer areas and unbunded higher contaminated hardstanding areas. Buildings and structures which are likely to have potential oil flows either in general or as a result of an incident are identified in the document "Site discharge Source List" prepared by EDF

Energy. However precise details and locations will be determined as a consequence of risk assessment.

2A.6.19 The SEE network will be sized on the basis of worst case discharge from impermeable area, oil spill, fire hydrant operation individually or in combination. Fire stop manholes and means of isolation will be provided for incident control and safeguarding of the network.

2A.6.20 All three drainage systems will outfall to the Attenuation Pond at which they will converge after passing through a containment tank for settlement of solids and oil separation as required, before discharging via a common outfall pipe to the Cooling Water Outfall tunnel for disposal.

2A.6.21 Details of route and arrangement for connection to the Cooling Water Outfall tunnel are subject to detailed design.

d) Proposed Groundwater Interception and Disposal

2A.6.22 Following completion of construction and removal of the deep well dewatering facility, it is anticipated that groundwater levels will recover to their original levels in the range of 6–10mOD. This creates a potential risk of groundwater flooding of operational buildings and floatation pressures which could impact on structural stability. In order to mitigate these risks, groundwater galleries will be constructed around the perimeter of critical buildings to the south and west. Any ingress water will be intercepted and removed, being disposed to the Unit 2 Forebay. Groundwater levels will be controlled at a level of 8mOD.

2A.6.23 The rate of groundwater ingress cannot be determined with precision nor can its quality. However relative to cooling water discharge as stated in A1.6.3 quantity/quality impacts will be minimal.

2A.6.24 Geotechnical investigation indicates that groundwater tends to flow from south to north. If in practice it is found that groundwater flow from the east creates potential problems construction of an additional eastern groundwater gallery may be considered.

e) Surface Water Network Design

2A.6.25 Design of roof drainage and underground pipework will be in accordance with:

- BS EN 752 Drain and Sewer Systems outside Buildings.
- BS EN 12056 Gravity drainage systems inside Buildings.
- Building Regulations Approved Document H.

2A.6.26 Specification of works will be in accordance with:

- Civil Engineering specification for the Water Industry (CESWI).
- Sewers for Adoption.
- Building Regulations Approved Document H.
- Highways Agency Design Manual for Roads & Bridges (DMRB).

2A.6.27 Given the location, layout and ground levels within the development the design will need to address specific issues.

2A.6.28 The flood risk requirement is that there shall be no surface water flooding as a result of a 100 year (1.0%AEP) rainfall event. It is necessary to ensure that all drainage pipes have capacity to pass the 100-year flows without surface flooding. This can be established by modelling of the network and routing of flows, whilst allowing the network to surcharge in manholes but not permitting surcharge levels to reach ground level. This ensures that all water which enters the drainage network can be removed for disposal.

2A.6.29 The design must also ensure that rainwater can be removed from impermeable surfaces such as roads. Since road design is normally based on lesser flood risk standards with permitted temporary ponding of water in gutter areas, typical gulley, channel drain, kerb drain sizing and spacing will be inadequate. Highway gullies are normally effective where there are reasonable longitudinal gradients which will direct flow along the gutter to the nearest gulley. In this case the site ground levels are flat although it is accepted that there must be some fall.

2A.6.30 Report “Networks Conceptual Design – Onsite Highways” specifies that if gullies are provided the minimum fall required is 0.5%. For channel and slot drains this can reduce to 0.1%.

2A.6.31 Given the exposed location and the extent of vertical faces of buildings there will be a need to make provision for removal of wind-blown rain which runs down the sides of buildings. BS EN 12056 requires that for design purposes an impermeable area of 50% of total vertical face should be allowed in runoff calculations. By virtue of the runoff collecting at ground level it is likely to be more contaminated and will be discharged to the SEO-EP road drainage network.

f) Surface Water Network Design – Safety Case

2A.6.32 Given that the surface water drainage network is designed to ensure that no surface flooding will occur due to a 100-year rainfall event it follows that a more extreme event will result in surface flooding of roads and paved areas due to either drains being overloaded such that water level reaches ground level or inability of gullies, channel drains and kerb drains to remove surface water from roads.

2A.6.33 In the case of roofs, the capacity of outlets and downpipes will start to be exceeded such that ponding on flat roofs will occur.

2A.6.34 Consideration has been given to increasing the size and capacity of drains so that a 10,000 year (0.01%AEP) rainfall event does not cause surface flooding and roofs are adequately drained. This would result in a need for excessively large diameter pipes and the disadvantage that under more frequent rainfall events there would be low proportional depths resulting in lack of self-cleansing flows. There would also be difficulty in providing sufficient road gullies and channel drains with capacity to remove all surface water from the roads.

2A.6.35 Accordingly Safety Case 10,000 year (0.01%AEP) runoff will be handled by a combination of Sustainable Drainage (SuDs) and Flooding Resiliences measures.

2A.6.36 Measures considered included a combination of:

- provision or ramps or steps at points of access to critical buildings so as to create a threshold above general ground level;
- managed overland flow flood routing within roads and away from buildings directing towards the lowest point at the sea wall;
- diversion of flow into groundwater galleries;
- underground or above ground designated storage; and
- high-level overflows to drain roofs.

2A.6.37 Taking account of relevent factors such as site layout, security, operational resiliance and health and safety, the measures to be incorporated in detailed design will consist of:

- provision or ramps or steps at points of access to critical buildings so as to create a threshold above general ground level;
- managed overland flow flood routing within roads and away from buildings directing towards the lowest point at the sea wall; and
- provision of drainage capacity to remove safety case rainfall intensity event flows from critical building roofs.

g) Sustainable Drainage

2A.6.38 The normal benefit of SuDS infiltration through recharging of groundwater is detrimental since there will be a requirement to control groundwater levels in order to protect the structural stability of critical infrastructure.

2A.6.39 Given the intensity of development and the criticality of the operational site there is limited scope for use of SuDs storage techniques in the form of ponds or tanks. It is also the case that since surface water disposal is to be through the Cooling Water Outfall tunnel the usual requirement for attenuation and greenfield runoff to mitigate effect of increased flow rate in receiving watercourse is not applicable.

2A.6.40 However above ground SuDs in the form of rainwater harvesting and green roofs will be provided. Whilst the primary driver for use of these techniques is ecological, they will attenuate surface water runoff.

2A.6.41 Rainwater harvesting is proposed for the Training and Simulator building. The extent and arrangement of the system is subject to detailed design.

2A.6.42 Sedum green roofs are specifically designed to support plant and wildlife providing a natural replacement for the footprint of the building. They also reduce peak rate of flow to the drainage system through the absorption of rainwater. Sedum roofs will be provided for a number of buildings including the Main Access Control Building, Outage Access Control Building, Medical Centre, Garage for Handling facilities, Oil and Grease storage and Oil Ancillary Building, the Simulator Building/Training Centre, the Public Information Centre and the EDF Site Offices. The total area of sedum roof coverage is approximately 14,500m^2.

2A.6.43 Green roofs are not suitable for some operational buildings since green roofs provide insulation and there is a requirement to dissipate heat through the roof structure.

h) Permanent Sea Wall

2A.6.44 A mass concrete permanent sea wall will be constructed over approximately 760m along the coastal frontage of the site. The dual purpose of the sea wall is to protect against erosion and limit the risk of flooding of the operational site due to wave overtopping.

2A.6.45 The soffit level of the precast concrete balustrade which is set on top of the mass concrete structure is 13.50mOD. The ground level of the coastal path located behind the balustrade is 12.40mOD. A slope of variable gradient links the operational platform (level 14.0mOD) with the coastal path.

2A.6.46 The Sea Wall is designed to allow removal of water which may accumulate through the wall for discharge to the foreshore. The sources of water are:

- Overland flow due to rainfall exceedance events of greater than 1 in 100 year.
- Wave overtopping of the sea wall.
- Groundwater flows.

2A.6.47 A channel will be installed at the base of the slope and rear of the coastal path. This channel will provide drainage for the coastal path and also collect surface water runoff and wave overtopping water. Pipes of suitable diameter and spacing to be confirmed as part of detailed design will discharge water from the channel through the sea wall. In the event that the pipes are unable to cope, water level will build up and discharge through the two 1.5m pedestrian access breaks points and the 5.0m vehicular access break in the sea wall. If water levels back up the slope to the rear of the channel water will infiltrate into the ground where it will be removed with other groundwater.

2A.6.48 A layer of free draining backfill will be placed to the rear of the mass concrete wall. This will allow water which infiltrates the ground and groundwater to migrate to a lower level drainage system. This will prevent pressure build up behind the sea wall which could result from groundwater mounding. Under baseline conditions groundwater runs in a south to north direction and exits the existing cliff face via seepage.

2A.6.49 The design of this low level drainage system has been set with the provision of 150mm pipes which will pass through the mass concrete wall at a spacing of one pipe per 10 linear metres. The invert levels of the pipes on the landward side will be in the range 4.5 – 5.5mOD and each pipe will have a vertical fall of 0.5m to the seaward side. It is intended that this arrangement will control groundwater levels such that they will not exceed 6.0mOD.

2A.6.50 The construction of the Sea wall will have to accommodate the temporary Foreshore Outfall pipe. This pipe with a diameter of approximately 2.1m. It will require to remain in use until such time that all flows from the Built Development can discharge via the Cooling Water Outfall Tunnel.

i) Water Quality Measures

2A.6.51 Whilst the volume of surface water discharged into Bridgewater Bay via the Cooling Water Outfall tunnel is not significant relative to the receiving water body, the quality of the discharge needs to be effectively controlled.

2A.6.52 Car park drainage will be compliant with recommendations contained in EA Pollution Prevention Guidance Note 3 and passed through suitably sized Class 1 bypass interceptors.

2A.6.53 Where roads are drained via gullies, silt and debris will be held within the gulley pot. For channel drains and kerb drains, inline silt traps will be provided to manufacturers recommendations.

2A.6.54 All of these facilities will be maintained in accordance with an asset maintenance plan and cleansed in order to minimise reduction in water quality and siltation of drainage systems.

2A.6.55 All three surface water networks will pass through the Attenuation Pond. The roof drainage will pass through without treatment. The road drainage will pass through without treatment but with a facility to divert to treatment if there are concerns regarding water quality.

2A.6.56 All SEH network flows which have a high risk of hydrocarbon contamination will be treated within the Attenuation Pond containment tank before merging with the roof and road drainage flows. Treatment will consist of passing flow through separator and settlement tanks. There will be a facility to divert and retain flows which arise from dealing with fires. The estimated volume is 1,635m^3 but actual volume will be confirmed in the course of detailed design. Contaminated water held in retention will be disposed offsite to an approved facility.

j) Permanent Foul Water Sewer Network

2A.6.57 A separate foul water drainage system will be provided for collection and disposal of sewage and wastewater. The system has the EDF Energy designation SEO-EU/EV. No surface water will be connected to the foul water drains and measures to prevent ingress of surface water runoff during exceedance events will be considered.

2A.6.58 Flow rates from each building will be calculated from information provided by EDF Energy which will include number of persons based in the building and the presence of any catering facilities. Discharge units and flow rate will then be calculated in accordance with BS EN 12056 Gravity drainage systems inside Buildings. Flow rates from individual buildings will be cumulated from points of connection to the main foul drains in order to ensure sufficient capacity.

2A.6.59 Design of internal building foul water drains and connections to the main drains will be in accordance with:

- BS EN 752 Drain and Sewer Systems outside Buildings.
- BS EN 12056 Gravity drainage systems inside Buildings.
- Building Regulations Approved Document H.

2A.6.60 Design of main foul water drains will be in accordance with:

- BS EN 752 Drain and Sewer Systems outside Buildings.
- Sewers for Adoption.

2A.6.61 Specification of works will be in accordance with:

- Civil Engineering specification for the Water Industry (CESWI).
- Sewers for Adoption.
- Building Regulations Approved Document H.

2A.6.62 The drainage runs will be located along the line of roads in order to maximize access for maintenance. Given that the site is effectively flat with limited fall towards the PSTP it is anticipated that a wholly gravity network, compliant with design criteria for self-cleansing velocities will not be achievable. It is likely that there will be a need for one or more pumping stations. In terms of sewage treatment terminal inlet pumping stations can assist with consistency of treatment by delivering a more consistent trickle flow.

k) Permanent Sewage Treatment Plant

2A.6.63 Biological, chemicals and water loadings on the PSTP will be determined using the Table of Loadings for Sewage Treatment Systems from “Code of Practice Flows and Loads – 3 Sizing Criteria, Treatment Capacity for Sewage Treatment Systems” issued by British Water.

2A.6.64 At this time it is not possible to state with precision the number of persons on site and using sewage facilities. This will vary both over 24 hours and also dependent on site activity. Initial assessments were of the order of:

- Normal daytime 700
- During outage 1,100
- Night time 100
- Weekends 100

2A.6.65 The British Water document quoted gives loadings of:

- Flow 100 litres/person/day
- BOD 38 grams/person/day
- Ammonia 5 grams/person/day

2A.6.66 Typical specification for PSTP performance is:

- Suspended solids 20mg/litre
- BOD 30mg/litre
- Ammonia 5mg/litre

2A.6.67 It is accepted that consent to discharge will be required from the EA. Such consent may require higher standards than previous due to implementation of the Priority Substances Daughter Directive in 2016. An Environmental Permit Application has been made with a stated maximum loading of 1,750 persons and a treated volume of 175m^3/day. Discussion with the EA is in progress. Response to the application An UWWT final effluent sampling point will need to be provided. It is understood that the EA will require this to be at the outfall to the PSTP. The outfall will discharge to the Cooling Water Outfall Tunnel.

2A.6.68 Details of route and arrangement for connection to the Cooling Water Outfall tunnel are subject to detailed design.

2A.7 Permanent Surface Water Drainage Network - Southern Construction Area

a) Flood Risk Factors Holford Stream Catchment

2A.7.2 Holford Stream culvert and its associated headwalls and channels, constructed as part of Site Preparation Works will be retained as permanent structures.

2A.7.3 The Emergency Road will pass through the catchment linking Hinkley Point C site to the national road network at Shurton. The road should not be flooded during a 100 year (1.0%AEP) rainfall event.

b) Proposed Surface Water Networks

2A.7.4 Restoration of the land which will involve deep ploughing of subsoil and reintroduction of topsoil together with re-profiling of the surface levels will have the effect of improving the permeability of the strata.

2A.7.5 Measures will be introduced to prevent erosion of the surface due to runoff whilst vegetation is re-established.

2A.7.6 In addition it is intended that water features will be provided on the site of WMZs 4 and 5. It may be possible to modify the WMZs to form part of the water features. If this is not possible then they will require demolition.

2A.7.7 The impact of restoration as proposed will be to reduce rate of surface water runoff and peak flow rate in the Holford Stream with a return towards more normal greenfield runoff rates, currently achieved, over time. This will result in an overall reduction in flood risk.

2A.7.8 It is intended to use sustainable drainage (SUDs) techniques such as swales for disposing of runoff from the Emergency Road.

c) Flood Risk Factors Bum Brook Catchment

2A.7.9 The Emergency Road will pass through the catchment linking Hinkley Point C site to the national road network at Shurton. The road should not be flooded during a 100 year (1.0%AEP) rainfall event.

2A.7.10 The Emergency Road will have to cross the Bum Brook. A concept design has been prepared for a bridge over the Bum Brook. Arch soffit has been set at the Site Preparation Works FRA 1000 year flood level plus 600mm freeboard. It is anticipated that this will ensure conveyance of the 10,000 year (0.01%AEP) flood without drowning out of the bridge structure. However this will be confirmed as part of detailed design.

2A.7.11 Predicted levels have been calculated as part of the DCO FRA. Negotiations will take place with the EA regarding acceptable impact of the bridge and associated embankments on the flood plain. If necessary mitigation works can be undertaken to prevent increased level of flood risk.

d) Proposed Surface Water Networks

2A.7.12 There is a requirement to re-profile the side of the Bum Brook valley in order to both provide a barrier to mitigate visual intrusion of the HPC construction works and also match the Southern Construction Platform ground levels. This will require removal of topsoil and placing of material to create the required slopes. This work which will be undertaken after completion of Site Preparation Works will result in an increase in rate of surface water runoff and pluvial flow. In order to mitigate this increase WMZ6 will be created and will be required to hold runoff from a 30 year (3.33% AEP) flooding event whilst being permitted to discharge to the Bum Brook stream at greenfield runoff (Qbar) rates.

2A.7.13 The re-profiling of land surface and change of levels is expected to move the Bum Brook/Holford Stream watershed to a more southerly position thus marginally reducing runoff to the Bum Brook.

2A.7.14 Once re-profiling is complete, cultivation and restoration will be undertaken in the same way for the Holford Stream catchment. WMZ6 will be replaced by a water feature.

2A.7.15 The impact of restoration as proposed will be to reduce the rate of surface water runoff and peak flow rate in the Bum Brook with a return towards more normal greenfield runoff rates over time. Taking into account the adjustment in watershed, an overall reduction in flood risk is anticipated.

2A.7.16 It is intended to use sustainable drainage (SUDs) techniques such as swales for disposing of runoff from the Emergency Road.

2A.8 Temporary – Permanent Drainage Transition and Management

a) Built Development Areas East and West

2A.8.2 Site layout and drainage work required as part of Site Preparation Works construction is well understood. Approval of the temporary/permanent drainage works included in Site Preparation has been obtained from the EA, PIDB and WSC. Site layout and drainage work required as part of Site Preparation Works construction is well understood. Approval of the temporary/permanent drainage works included in Site Preparation will be obtained from the EA, PIDB and WSC.

2A.8.3 Permanent layout of the power station together with associated buildings and support infrastructure has been confirmed through completion of design Phase 1. Locations of the Attenuation Pond, permanent STP and final points of discharge for disposal of treated final effluent and surface water are fixed.

2A.8.4 The fixing of permanent final layout of the power station also establishes routes for both permanent and temporary foul water and surface water drainage.

2A.8.5 Based on the original programme, it was intended that Site Preparation Works contractor would be required to provide a temporary works drainage design based on the WMZ concept shown in **Figure A.1.6.** This would include design of the WMZs, spine drains, collector drain and foreshore outfall structure. This design arrangement was based on the belief that design of permanent drainage would not be undertaken before Site Preparation Works construction had commenced. However the current programme shown in **Table A.1.1** indicates that design of permanent drainage will commence in the fourth quarter of 2011 whilst construction of Site Preparation Works drainage will not commence until the second quarter of 2012. As a result and subject to suitable levels/WMZ design, it may be possible for the spine drains and collector drains to be designed for incorporation in permanent works.

2A.8.6 Whilst it may be possible subject to detailed design to construct some Site Preparations Work drains as permanent, there will still be a need for temporary drains and transitional structures, including WMZs and Foreshore Outfall.

2A.8.7 The existing Hinkley Point C drainage ditch and its foreshore outfall will require to remain in place and in use until the temporary Foreshore Outfall structure is complete. EWMZ1/2 will be required in order to control flow rate and ensure water quality standards are maintained. The existing Hinkley Point C drainage ditch and its foreshore outfall will require to remain in place and in use until the temporary Foreshore Outfall structure is complete. EWMZ1/2 will be required in order to control flow rate and ensure water quality standards are maintained in compliance with Environmental Permit specified criteria.

2A.8.8 Once the temporary foreshore outfall structure is complete and available for use the collector drain can be constructed. At this point permanent/temporary drainage can be diverted into the collector drain via WMZs 1, 2 and 3.

2A.8.9 Ancillary Building Zone will be the first area to be constructed. Because it is at the upstream limit of the site, permanent drainage will need to pass through temporary spine drains designed by the SPW contractor. Permanent drainage constructed as part of this phase will be sized for the 100 year (1% AEP) rainfall event with no surface flooding but will connect into temporary spine drains which are designed for the 30 year (3.3% AEP) rainfall event. However there is a requirement to plan for exceedance and manage overland flow. As a result the downstream lack of 100 year (1% AEP) spine drain capacity will not create unacceptable risk of flooding. In fact the additional capacity in permanent drains will create additional underground storage volume available in a 30 year (3.3% AEP) event potentially reducing flood risk. This will be subject to hydraulic modelling as part of permanent works design.

2A.8.10 As an alternative the spine drains may be designed as permanent in which case they will also be sized for the 100 year (1% AEP) rainfall event with no surface flooding.

2A.8.11 Power Station Unit 1 located to the east and downstream of the Ancillary Building Zone will be the next area to be constructed. This will include construction of the Attenuation Pond and the permanent sewage treatment works. Permanent foul and surface water sewers constructed in the Ancillary Building Zone will be extended to these outfall points. The effect of this will be to provide a greater and level of flood risk protection to the Ancillary Building Area whilst providing 100 year (1% AEP) rainfall event protection, with no surface flooding.

2A.8.12 Construction of Power Station Unit 2 will be the last main area of construction. Permanent foul and surface water sewers constructed in the Ancillary Building Zone will be connected to the new drains.

2A.8.13 At this stage all permanent surface water and foul water drains will be in place and available for use. However some elements of temporary drainage will need to remain in place.

2A.8.14 WMZs 1, 2 and 3 will need to remain in place and use until such time as the Attenuation Pond treatment facility is complete, commissioned and in operation. At this stage the WMZs can be abandoned and all surface water flows will pass through Attenuation Pond.

2A.8.15 There will be a need for a temporary connection from the Attenuation Pond to the collector drain and Foreshore Outfall structure to provide a discharge point for all surface water and groundwater. This outfall will be required until such time as the Surge Chamber and Cooling Water Outfall are in operation. Once all flows have been diverted to the Surge Chamber on a permanent basis the collector drain and Foreshore Outfall are no longer required.

2A.8.16 Although it is expected that the TSTPs will be constructed and commissioned without delay, during initial construction there will be a need to provide temporary holding tank facilities for collection of sewage. Sewage will be removed by tankering.

2A.8.17 TSTPs will be provided for use during construction of Phase 2, 3 and 4 permanent works. The location of TSTPs is in catchment 1, Phase 4. These facilities will need to remain in place and available until such time as the PSTP is complete, commissioned and in use at which time they can be either abandoned or outfalls transferred to permanent foul water drains.

2A.8.18 Phase 2 Ancillary Building Zone will be complete prior to construction of the PSTP, as part of Phase 3. If the facilities are occupied at this stage temporary sewage disposal arrangements will be required. It is likely that flows could be passed to one of the TSTPs pending permanent treatment availability.

2A.8.19 There will be a need for a temporary connection from the PSTP to the collector drain and Foreshore Outfall structure to provide a discharge point for all surface water and groundwater. This outfall will be required until such time as the Surge Chamber and Cooling Water Outfall are in operation. Once all flows have been diverted to the Surge Chamber on a permanent basis the collector drain and Foreshore Outfall are no longer required.

2A.8.20 Consideration was given to continued use of the temporary Foreshore Outfall structure but discounted on grounds of security and maintenance liability. It will be removed and the Sea Wall made good. However consideration will be given to method of abandonment and Sea Wall finishing works with a view to recreation of an outfall at the same location upon decommissioning of the power station.

2A.8.21 The final construction will be of the Interim Spent Fuel Facility. Drainage of this facility will connect into the permanent drainage network constructed as part of Unit 1Southern Construction Area Holford Stream and Bum Brook catchments

2A.8.22 Significant elements of work undertaken as part of Site Preparation Work such as the Holford Stream culvert will be permanent structures. Drainage provision in the form of ditches and gravel filled drains will be kept in the same approximate position but require continuous modification as construction platforms are raised. However once platforms and stockpiles are complete it is anticipated that the drainage facilities will be effectively permanent until restoration of the land to form a nature reserve.

2A.8.23 As part of the proposed landscape restoration scheme it is intended that water features will be provided on the site of WMZs 4, 5 & 6. It may be possible to modify the WMZs to form part of the water features. If this is not possible then they will require demolition.

2A.8.24 Effectively the distinction between temporary and permanent works is blurred and the final drainage arrangements are expected to be an adaption of temporary rather than a new drainage system.

2A.9 Permanent Drainage Asset Maintenance

2A.9.1 The permanent drainage network has been designed with capacity to provide the level of protection against flood risk as specified by EA and ONR. The specification of drainage assets will be compliant with standards referred to in A1.6.49. This will minimise risk of operational failure of drainage assets which could result in a flooding incident.

2A.9.2 It remains the case that operational failure due to blockage or other asset failure presents a risk of flooding. This risk will be mitigated by a programme of planned asset maintenance, cleansing and inspection which will be undertaken by EDF Energy as owner of the development site.

2A.9.3 All drainage assets are located within the development. As a result it is not proposed that any drainage asset will be offered for adoption and all assets will remain in the ownership of EDF. Under the provisions of Floods and Water Management Act 2010, Schedule 3, there is no legal requirement to have SuDs drainage facilities located in private land offered for adoption.

2A.10 Decommissioning and Demolition of Hinkley Point C Power Station

2A.10.1 It is intended that the Hinkley C power station will cease to operate after approximately 60 years in around 2080. The Built Development Area will then be demolished in stages and it is currently expected that the land will be made available for further industrial use but with an interim period of grassland. It will be necessary to retain the Spent Fuel Storage Facility until approximately 2028 when the Government proposed Deep Waste Repository is due to become available. Final decommissioning is expected to be complete by 2036.

2A.10.2 As decommissioning proceeds, the drainage facilities will require gradual modification to continue effective operation, provision of flood protection and treatment of effluent/surface water runoff. Modification will need to take account of changed flow regimes and impacts on self-cleansing flows. Reduced loadings on the PSTP may impact on standard of final effluent will also need to be considered.

2A.10.3 At some point the Attenuation Pond surface water treatment facility will be demolished and there will be a requirement to replace it with a Class 1 bypass road drainage. The PSTP will need to remain in place until ultimate demolition of the Spent Fuel Storage Facility.

2A.10.4 As part of decommissioning the Cooling Water Outfall Tunnel will be sealed and above ground and sea bed features dismantled. It is intended that at this time all flow from surface water drains and treated final effluent from the PSTP will be diverted to a new outfall in the same location as the Foreshore Outfall Structure. The area occupied by the Build Development Area will be returned initially to its current undeveloped state but will subsequently be available for future development. Drainage ditches will be required to provide for the effective drainage of catchment 10 to the west and catchments 1-3.

APPENDIX 2B: OPERATIONAL LIGHTING STRATEGY

CONTENTS

TABLES

FIGURES

FIGURES IN TECHNICAL APPENDIX

[This page is intentionally left blank]

2B.1 Introduction

a) Outline

2B.1.1 This document, together with its appendices, describes the lighting strategy for the operational Hinkley Point C (HPC), and supports the DCO application to the Infrastructure Planning Commission (IPC). It also informs the Environmental Impact Assessment (EIA) and preparation of the Environmental Statement (ES).

2B.1.2 The lighting strategy for the construction of the HPC proposed development is available as a separate appendix to the **Construction Method Statement**.

2B.1.3 The HPC operational phase would commence at the start of Unit 1 generation, expected in 2019.

b) Project Description

2B.1.4 A detailed description of the HPC development is provided in the Description of Proposed Development, **Volume 2, Chapter 2** of the ES.

2B.1.5 The HPC permanent development would be located within the northern part of the HPC development site. The HPC development site is bisected by a track (Green Lane) running east-west, which would be retained and protected for most of its length. The landscape within the remaining parts of the HPC development site would be restored (see **Volume 2, Chapter 22** of the ES).

c) Aim of the Report

2B.1.6 This report provides the lighting strategy for the operational HPC development which complies with the Department for Communities and Local Government (CLG) guidance 'Lighting in the Countryside: Towards Good Practice' (Ref.1), other relevant guidance and British Standards (BS), and addresses the relevant technical, planning and environmental considerations.

2B.1.7 The strategy is focused on the external lighting proposals. Internal lighting of the HPC buildings is described in the **Hinkley Point C Development Site Design and Access Statement**.

2B.1.8 The strategy is supplemented by a Technical Appendix (see section 6), which describes technical details of the indicative operational lighting design.

d) Scope

2B.1.9 The scope of this report has been prepared in line with the outlined guidelines and, following this introduction (section 1), it contains the following sections:

- section 2: Site Context, which examines the relevant environmental conditions (predominantly landscape, visual and ecological) within and around the HPC development site as well as a summary of the relevant legislation, standards, good practice guidelines and policies;
- section 3: Objectives and Mitigation, which identifies the objectives for the lighting strategy (taking into account the opportunities and constraints identified in the previous section) and proposes mitigation measures;

- section 4: HPC operational lighting strategy for the operational phase of the HPC proposed development;
- section 5: Summary; and
- section 6: Technical Appendix.

2B.2 Site Context

a) Introduction

2B.2.1 This section examines the planning, legislative and environmental issues of relevance to the lighting strategy. A desktop study has been carried out to identify the main planning and environmental issues that should be taken into account when considering the impact of the operational HPC development on the local and wider area.

b) Site Location

2B.2.2 The HPC development site is located within the district of West Somerset (see **Figure 2B.1**). Two other local planning authority areas, namely Sedgemoor and Taunton Deane, lie within 10km of the site.

Figure 2B.1: Site Location

c) Study Area

2B.2.3 The study area for the site context appraisal covers the Landscape and Visual Impact Assessment (LVIA) wide study area described in detail in **Volume 2, Chapter 22** of the Environmental Statement (ES).

2B.2.4 The geographical extent of the LVIA study area under consideration includes:

- Lowland Somerset – up to 18km from the HPC development site;
- Exmoor National Park – up to 25km from the HPC development site;
- Mendip Hills AONB – up to 21km from the HPC development site; and
- Welsh coastline – up to 21km from the HPC development site.

d) Landscape Character

2B.2.5 For a detailed assessment of the landscape character within and around the site, see **Volume 2, Chapter 22** of the ES. A brief summary of the local landscape character is provided below.

2B.2.6 The HPC development site is located within the Quantock Vale Local Landscape Character Area (LLCA), on the northern coast of Somerset, which is characterised by rolling farmland containing wide valleys and gentle hills which are rarely above 60m Above Ordnance Datum (AOD).

2B.2.7 The Quantock ridge is a dominant feature to the south-west and the landform around the site is predominantly overlain by essentially an agricultural landscape of small fields, hedges, hedgerow trees and small woodlands. The local area of particular sensitivity to lighting is the strip of farmland located adjacent to the coast to the north-west of the site.

e) Legislation, Policy and Guidance

2B.2.8 The lighting strategy should comply with the following legislation:

- Health and Safety at Work Act 1974;
- The Environmental Protection Act 1990; and
- Wildlife and Countryside Act 1990 (as amended) and Conservation of Habitats and Species Regulations 2010.

i. Health and Safety at Work Act 1974

2B.2.9 The Health and Safety at Work etc. Act 1974, provides that suitable and sufficient lighting must be provided at all workplaces, including outdoor places. The Regulations cover activities to be carried out during the operation of the power station. EDF Energy's Health, Safety, Environmental and Quality policy statement places safety at the heart of the construction project and as such the primary aim of the lighting strategy is to ensure a safe working environment is maintained even in the absence of natural light.

ii. The Environmental Protection Act 1990

2B.2.10 The Environmental Protection Act 1990 (EPA 1990) was amended by section 102 of the Clean Neighbourhoods and Environment Act 2005 to add 'artificial light emitted from premises so as to be prejudicial to health or a nuisance' to the list of statutory nuisances set out in the EPA 1990. This does not apply to artificial light from lighthouses, prisons, airports, harbours and railway or tramway premises, nor to street lighting for public service or goods vehicles, however it would apply to the lighting emitted from the HPC development site.

2B.2.11 The lighting strategy will comply with relevant British Standards and the best practice guidelines prepared by the Chartered Institution of Building Services Engineers (CIBSE), Institute of Lighting Engineers, and the Dark Sky Association to minimise obtrusive light and ensure compliance with the Clean Neighbourhoods and Environment Act 2005/EPA1990.

iii. Wildlife and Countryside Act 1990 (as amended) and Conservation of Habitats and Species Regulations 2010

2B.2.12 All species of bat are protected by the Wildlife and Countryside Act 1981 (as amended) and the Conservation of Habitats and Species Regulations 2010. These Regulations make it an offence to harm or disturb bats (see **Volume 2, Chapter 20** of the ES for a full explanation of offences).

2B.2.13 A full list of Statutory Regulations and Electrical Works British Standards applicable to the Hinkley Point C proposed development is provided in the Technical Appendix. The key British Standards relevant to the operational lighting design are:

- BS EN 12464-2:2007 Lighting of Workplaces – Part 2: Outdoor Work Places; and
- BS 5489-1:2003 + A2:2008 Code of practice for the design of road lighting – Part 1: Lighting of Roads and Public Amenity Area.

iv. BS EN 12464-2:2007

2B.2.14 To enable people to perform outdoor visual tasks efficiently and accurately, especially during the night, adequate and appropriate lighting has to be provided. The degree of visibility and comfort required in a wide range of outdoor work places is governed by the type and duration of activity.

2B.2.15 This standard specifies requirements for lighting tasks in most outdoor work places and their associated areas in terms of quantity and quality of illumination.

2B.2.16 Tables scheduling areas, tasks and activities relevant to this development are as follows:

- Table 5.1 General Circulation Areas
- Table 5.2 Building Sites
- Annex A Additional recommendations with respect to safety and health of workers at work.

v. BS 5489-1:2003 + A2:2008

2B.2.17 This standard gives recommendations on the general principles of road lighting, as well as on aesthetical and technical aspects, and advises on statutory provisions, operations and maintenance.

2B.2.18 It gives recommendations for the design of lighting for all types of highways and public thoroughfares, including those specifically for pedestrians and cyclists, and for pedestrian subways and bridges.

2B.2.19 The standard will be used to ensure that statutory design criteria are met where the primary roads in the development site interface with the surrounding public road network.

2B.2.20 The HPC Operational Lighting Strategy takes into account the relevant guidance, namely:

- Lighting in the Countryside: Towards Good Practice;
- The Society of Light and Lighting (SLL) Lighting Handbook 2009;
- Institute of Lighting Engineers (ILE) (2005) Guidance notes for the reduction of obtrusive light;
- Bat Conservation Trust – Bats and Lighting in the UK version 3 May 2009; and
- International Dark Sky Association.

vi. Lighting in the Countryside: Towards Good Practice

2B.2.21 Lighting in the Countryside: Towards Good Practice was issued by the then Department of the Environment in 1997. The purpose of the Good Practice Guide is to provide practical advice on the prevention and control of lighting impacts and identifies a number of objectives that should be considered when developing the lighting strategy.

vii. The SLL Lighting Handbook

2B.2.22 The SLL Lighting Handbook provides further guidance behind the specific requirements of the British Standards and also identifies other sources of technical information.

viii. ILE Guidance Notes

2B.2.23 The ILE guide specifically identifies the sources of obtrusive lighting and provides further explanation of the British Standard requirements.

ix. Bats and Lighting in the UK (Version 3, May 2009)

2B.2.24 The Bat Conservation Trust report aims to raise awareness of the impact of lighting on bats and suggests mitigation measures to minimise the impact resulting from various scenarios.

x. International Dark Sky Association

2B.2.25 Dark Sky policy refers to the aims of the International Dark Sky Association (IDA) with regards to the avoidance of light pollution. The IDA's goals are to be effective in stopping the adverse environmental impact on dark skies by building awareness of the problem of light pollution and of the solutions.

2B.2.26 IDA describes light pollution as any adverse effect of artificial light including sky glow, glare, light trespass, light clutter, decreased visibility at night, and energy waste. The IDA has a number of policy initiatives and collates technical information identifying best practice for avoiding light pollution.

2B.2.27 Lighting can have a significant impact on the landscape character and visual receptors. The legislation, policy and guidance relevant to the landscape and visual issues in relation to the HPC proposed development are examined in **Chapter 22**, **Volume 2** of the Environmental Statement.

f) Lighting Baseline Condition

2B.2.28 The HPC development site lies within an area with dark skies at night and the only significant source of lighting in the vicinity of the HPC development site is the existing Hinkley Point Power Station Complex. **Figure 2B.2** illustrates the existing Hinkley Point B power station at night[1].

Figure 2B.2: Photo of Existing Hinkley Point Power Station Complex at Night

2B.2.29 The site was visited in October 2010 and four initial views were recorded to illustrate the level of existing lighting at night. Viewpoint locations are shown on **Figure 2B.3**. **Figures 2B.4** to **2B.7** illustrate the views of the existing Hinkley Point Power Station Complex from receptors located around the site, including the West Somerset Coast Path, landscape to the south-east of the site and two views from the Quantock Hills Area of Outstanding Natural Beauty (AONB).

2B.2.30 Additionally, 13 locations were selected for dusk views and agreed with statutory consultees during informal consultation in April 2011. Site visits to record the views were carried out in June and July 2011. Baseline photographs of all 13 dusk views

[1] Source: Water.Technologies.net a product of Net Resources International

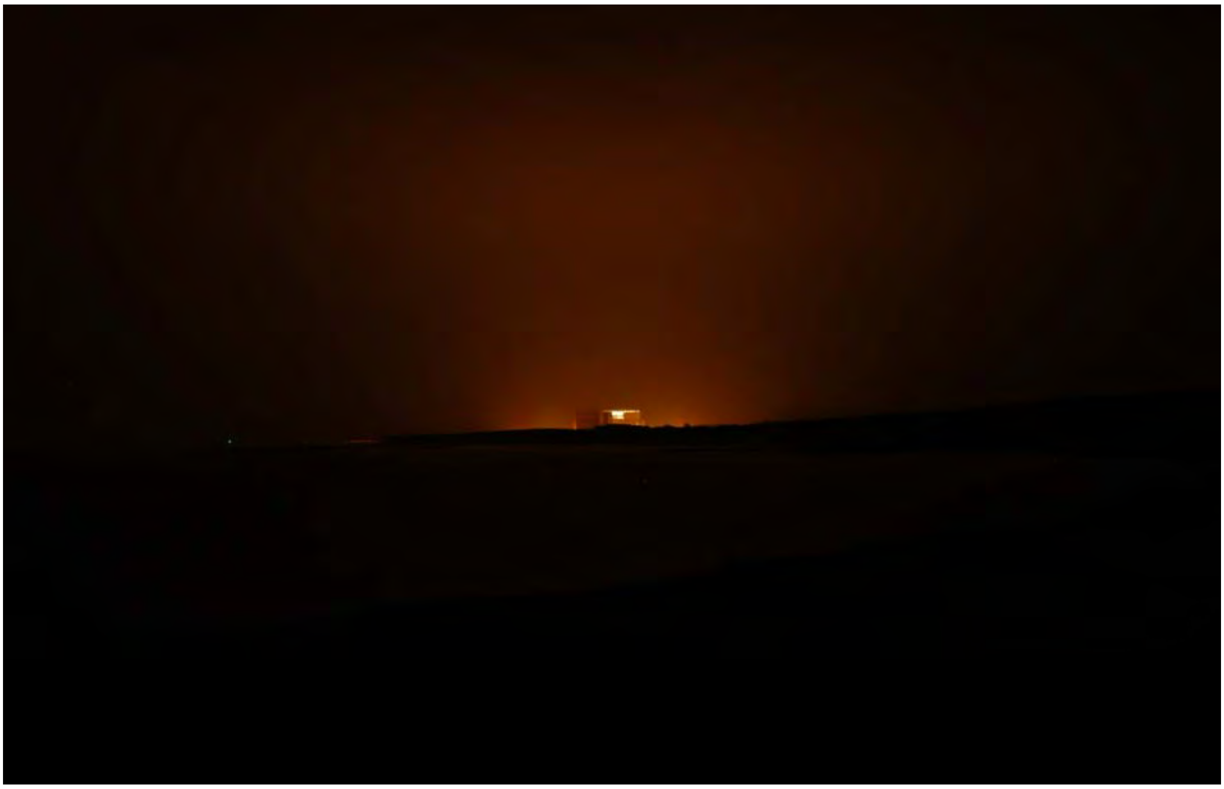
are included in the Technical Appendix. Full resolution baseline dusk photographs are presented in **Volume 2, Chapter 22** of the ES**.**

2B.2.31 The locations were selected from Principal Viewpoints for the LVIA (refer to **Volume 2, Chapter 22**) agreed with statutory consultees. The locations of all viewpoints are shown on **Figures 22.9** and **22.9a** in **Volume 2**, **Chapter 22** of the ES.

Figure 2B.3: Viewpoint Locations – Night Views

2B.2.32 **Figure 2B.4** illustrates a night view from the West Somerset Coast Path north of Lilstock (Public Right of Way (Prow) No. WL24/10). This viewpoint is located approximately 2.4km from the HPC development site boundary and is included in **Volume 2, Chapter 22** of the ES as Principal Viewpoint 3.

Figure 2B.4: Lighting Baseline: Night View 1 – Lilstock, Coastal Footpath



2B.2.33 **Figure 2B.5** illustrates a night view from Hilltop Lane located within the north-eastern fringes of the Quantock Hills AONB. This viewpoint is located approximately 4km from the HPC development site and is representative of views from the north-eastern part of the Quantock Hills AONB.

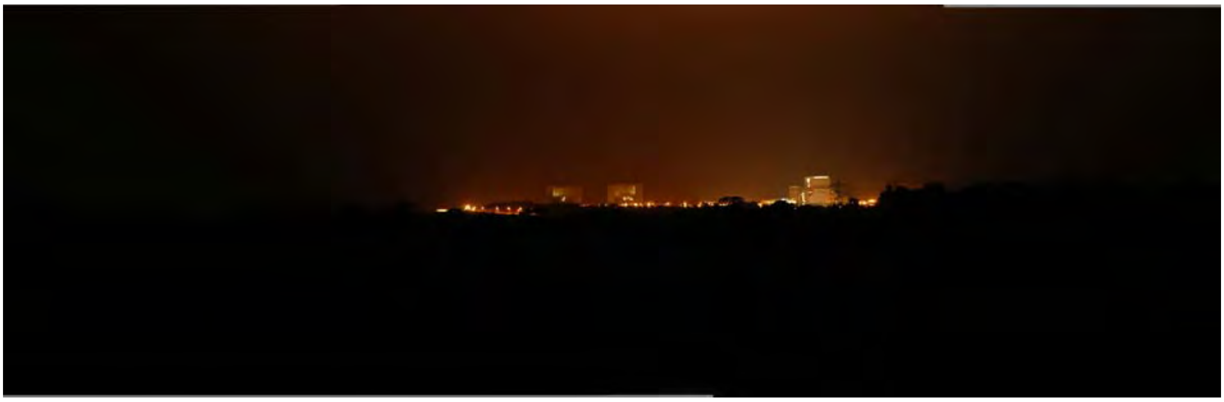
Figure 2B.5: Lighting Baseline: Night View 2 – Hilltop Lane, Quantock Hills AONB

2B.2.34 **Figure 2B.6** illustrates a night view from the A39 layby within the Quantock Hills AONB. This viewpoint is located approximately 5.5km from the HPC development site and is representative of views from the eastern edge of the Quantock Hills AONB and the A39.

Figure 2B.6: Lighting Baseline: Night View 3 – A39, Holford Layby, Quantock Hills AONB

2B.2.35 **Figure 2B.7** illustrates a night view from a local road approximately 0.6km south of the existing Hinkley Point Power Station Complex. The viewpoint is included in **Volume 2, Chapter 22** of the ES as Principal Viewpoint 12.

Figure 2B.7: Lighting Baseline: Night View 4 – Local Road to the South of the Site



2B.2.36 All recorded night views show the existing Hinkley Point Power Station Complex as a source of significant light pollution due to poor control of light distribution and poor colour rendering of the existing lights (orange low pressure sodium lights). **Figure 2B.7** illustrates direct glare from the lights and that there is minimal control of horizontal light distribution, which causes problems with light spill and direct upward light. These problems enhance the glow effect from the development.

g) Environmental Considerations

2B.2.37 Protection of the environment is a key consideration in developing a lighting strategy for the operation of Hinkley Point C. It is recognised that the development site is located within an area with several environmental constraints. They include:

- area of dark skies and landscape character sensitive to light sources;
- the Quantock Hills AONB which overlooks the site from the south-west and Mendip Hills AONB is located to the north-east of the site;
- Exmoor National Park is located approximately 14km to the west of the site;
- the site is located adjacent to an area of outstanding scenic interest; and
- designated sites of ecological importance including SSSI, RAMSAR and SPA providing habitat for important bird species (see **Volume 2, Chapter 20** of the ES).

2B.2.38 A minimum of 10 bat species have been recorded as using the HPC development site, including lesser and greater horseshoe and barbastelle bats for commuting and foraging. The Green Lane through the centre of the site, Benhole Lane along the western boundary and the Bum Brook along the southern boundary have been identified as 'key' bat corridors (see **Volume 2, Chapter 20** of the ES).

2B.2.39 There are no local landscape designations that cover any part of the landward element of the HPC permanent development site. However, there are a number of local planning designations covering landscapes of particular interests that are present in the LVIA study area. A full list of landscape designations is provided in **Volume 2, Chapter 22** of the ES.

2B.2.40 There are a number of PRoW crossing the HPC development site and in its immediate vicinity, including a coastal path which runs along the top of the low cliff line. For more details please refer to **Volume 2, Chapter 25** of the ES.

2B.2.41 There are no known sites of international importance for cultural heritage within the HPC development site, however a Scheduled Monument (Wick Barrow, also known as Pixies Mound) is located to the east of the proposed HPC development. There are also no listed buildings within the HPC development site. An important Grade II* listed building, Fairfield House, is located approximately 3km south-west. For more details on Scheduled Monuments and listed buildings please refer to **Volume 2, Chapter 23** of the ES.

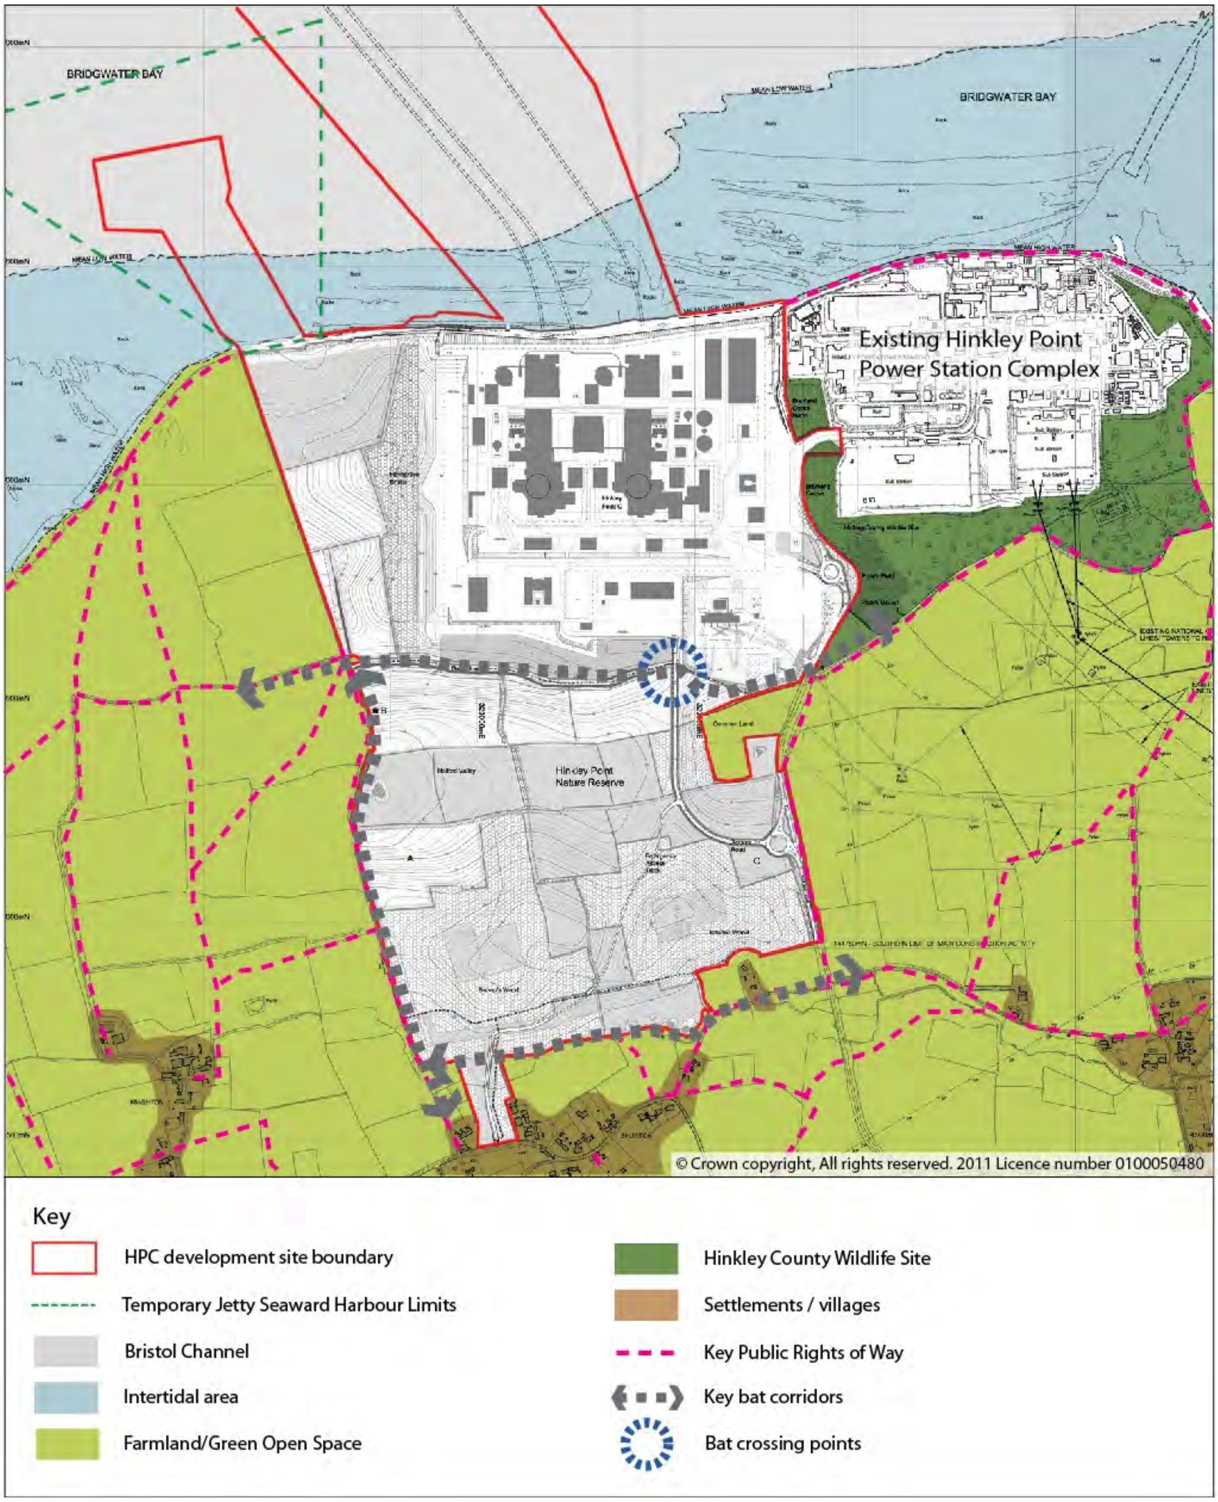
h) Key Local Lighting Receptors

2B.2.42 The analysis of the site context, landscape character and environmental constraints led to the identification of several key local receptors which have the potential to be affected by the proposed lighting. Key local lighting receptors are selected based on the professional judgement of the environmental assessors and include landscape, visual, historic, ecological or amenity receptors which are located either in close proximity to the HPC development site or are of high sensitivity and have the highest potential to be impacted by the HPC operational lighting. Lighting impacts on all relevant receptors is assessed in the relevant ES chapters.

2B.2.43 Key local lighting receptors identified, include (see **Figure 2B.8**):

- settlements/hamlets of Wick, Shurton, Burton and Knighton and Doggetts farm;
- users of PRoW in the vicinity of the site;
- Bridgwater Bay;
- intertidal area (encompassing the Severn Estuary SPA/Ramsar and Bridgwater Bay SSSI);
- Hinkley County Wildlife Site lying partly within the HPC development site and around the existing Hinkley Point Power Station Complex;
- areas of farmland around the site; and
- key bat corridors (in particular corridors running through the HPC development site).

Figure 2B.8: Key Local Lighting Receptors



i) Key Lighting Receptors in the Wider Context

2B.2.44 Other receptors located within the LVIA study area and considered in the lighting strategy include (see **Figure 2B.9**):

- Quantock Hills AONB;
- Mendip Hills AONB;
- Exmoor National Park;
- Areas of outstanding scenic interest; and
- Elevated areas of farmland within the study area represented by Principal and Secondary Viewpoints (see **Volume 2, Chapter 22** of the ES).

Figure 2B.9: Key Lighting Receptors (Wide Site Context)

2B.2.45 The Quantock Hills AONB is located at its closest approximately 3.7km to the south-west of the HPC development site. The AONB covers an area of about 125km² and reaches a height of 384m overlooking the development site. The Mendip Hills AONB lies approximately 19.5km north-east of the HPC development site.

2B.2.46 Exmoor National Park is situated within the counties of Somerset (71% of the park) and Devon. The boundary of the National Park is located approximately 14km, and beyond, to the west of the HPC development site.

2B.2.47 The HPC development site is bounded by an area of outstanding scenic interest, which extends further to the south-west.

j) Consultation

2B.2.48 The need for assessment of HPC operational lighting was confirmed during consultation. The selection of representative night and dusk viewpoint locations was agreed with the consultees in April 2011.

[This page is intentionally left blank]

2B.3 Objectives and Mitigation

a) The Need for Lighting

2B.3.2 The primary aim of the operational lighting proposal for the HPC proposed development is to ensure that, in the absence of natural light, a safe working environment is maintained.

2B.3.3 Due to the proximity of nationally protected landscapes, the Quantock Hills AONB and an area of outstanding scenic interest, the HPC development site has been categorised as lying within an Environmental Zone E1 which requires the maximum control and limitation of intrusive light sources on the surrounding landscape in accordance with the legislation, planning and guidance.

2B.3.4 As defined in the BSEN 12464, Designated Environmental Zone E1 is an “intrinsically dark area such as national parks or protected sites”. Zone E2 is defined as “low district brightness areas, such as industrial or residential rural areas”. The HPC Operational Lighting Strategy should comply with the Environmental Zone E1 standard.

2B.3.5 A lighting system would be required for the following external areas of the HPC permanent development:

- roads and pedestrian footpaths (internal to site boundary);
- car parks;
- perimeter and High Security Area (HSA) fences;
- vehicle inspection areas;
- off-site vehicle search area;
- road lighting designed for traffic routes ME3a lighting class and conflict areas CE2 lighting class; and
- the National Grid 400kV Substation.

2B.3.6 The HPC development would be a source of internal lighting from several HPC buildings. Details of the internal lighting proposals are included in the **Hinkley Point C Design and Access Statement**.

2B.3.7 The primary objectives of the lighting strategy shall be to achieve the following:

- comply with planning requirements;
- meet key standards and statutory requirements;
- provide a safe working environment;
- allow 24 hour working;
- target lighting at where it is required;
- avoid over illumination;
- avoid upwards lighting;
- avoid light spill to neighbouring areas;

- minimise energy consumption; and
- minimise disruption to bat corridors.

b) Approach

2B.3.8 The lighting strategy recognises the requirements of health and safety and protection of the environment and aims to minimise the impact of light on important receptors in the following ways:

- the lighting scheme must allow for safe operation of HPC and ensure the scheme's compliance with all relevant health and safety standards;
- the lighting scheme should attempt to minimise the amount of light spill to areas outside the working or access areas. Wherever possible, this requirement would be met by considering the number of fittings and their mounting height; an overall lighting requirement can be met by a smaller number of high output fittings mounted at a higher elevation or a higher number of smaller output fittings mounted at lower level. The use of downward facing lighting fittings (directional lighting) would also reduce the amount of light spill;
- HPC development would require 24 hour working during operations;
- the only permanent lighting outside the HPC permanent development area would be installed at the southern roundabout on Wick Moor Drove.

c) Mitigation

2B.3.9 A range of mitigation measures are available to address the potential lighting impacts.

2B.3.10 As part of the mitigation measures to minimise light spill, the following should be considered:

- design to correct illumination levels. Do not over-light an area thus avoiding adding to sky glow;
- move luminaires away from boundaries;
- use of shields and baffles to reduce light spill to a minimum;
- introduce controls to avoid unnecessary night time lighting; and
- ensure luminaires are orientated correctly following installation.

2B.3.11 As part of the mitigation measures to minimise upwards light and distant visual impact, the following should be considered:

- use of full cut-off exterior luminaires to avoid light above the horizontal;
- direct light downwards wherever possible to avoid sky glow; and
- ensure appropriate luminaires are chosen.

2B.3.12 As part of the mitigation measures to minimise the impact of lighting on bats, the following should be considered:

- type of lamp to minimise UV content;

- light spill control to avoid obtrusive light;
- height of lighting columns to be considered to reduce risk of light spill; and
- lighting levels to be kept to the minimum required to achieve a safe working environment.

2B.3.13 In addition to lighting mitigation measures, several retained and proposed landscape features within and around the HPC development site would contribute to lighting mitigation. These features are illustrated on **Figure 2B.10** and include:

- Existing and proposed landform which reduce the potential impact of lighting on surrounding farmland, local settlements and PRoW in the vicinity of the HPC development site. Existing topography includes the Green Lane ridge (majority to be retained) and local rolling landform around the HPC development site which would reduce impact of lighting from the nearby villages, hamlets and farms to the south and south-west of the HPC development site.
- Strong hedgerow field pattern and woodland blocks and scrub, including advance screen planting implemented in the spring of 2011 and early restoration proposals within the southern part of the HPC development site, would contribute to reducing the impact of lighting due to a degree of enclosure they provide.
- Retained Hinkley County Wildlife Site, which contains mature woodland areas and partially screens the flat and open Wick Moor.
- Large areas of woodland and hedgerow planting to the south of the Green Lane ridge.

2B.3.14 Details of the final landscape design outside the HPC permanent development are described in **Volume 2, Chapter 22** of the ES.

Figure 2B.10: Local Lighting Mitigation

Key

- HPC development site boundary
- Temporary Jetty Seaward Harbour Limits
- Green Lane ridge, existing rolling landform and proposed screening bunds reduce impact of lighting on surrounding farmland, PRoW and local settlements
- Retained Hinkley County Wildlife Site helps screen the flat and open Wick Moor
- Strong hedgerow field patterns & woodland blocks/scrub, including screen planting: define and enclose land, reduce impacts inland

2B.4 HPC Operational Lighting Strategy

a) Operational Lighting Proposals (External)

2B.4.1 For the purpose of this lighting strategy, the HPC proposed development has been divided into six external lighting zones. These are illustrated on **Figure 2B.11** and are as follows:

- roads and pedestrian footpaths (internal to site boundary);
- car parks;
- perimeter and HSA fences;
- vehicle inspection areas;
- off-site vehicle search area;
- road lighting designed for traffic routes ME3a lighting class and conflict areas CE2 lighting class; and
- the National Grid Substation.

2B.4.2 Additionally, permanent road lighting would be installed at the southern roundabout at Wick Moor Drove.

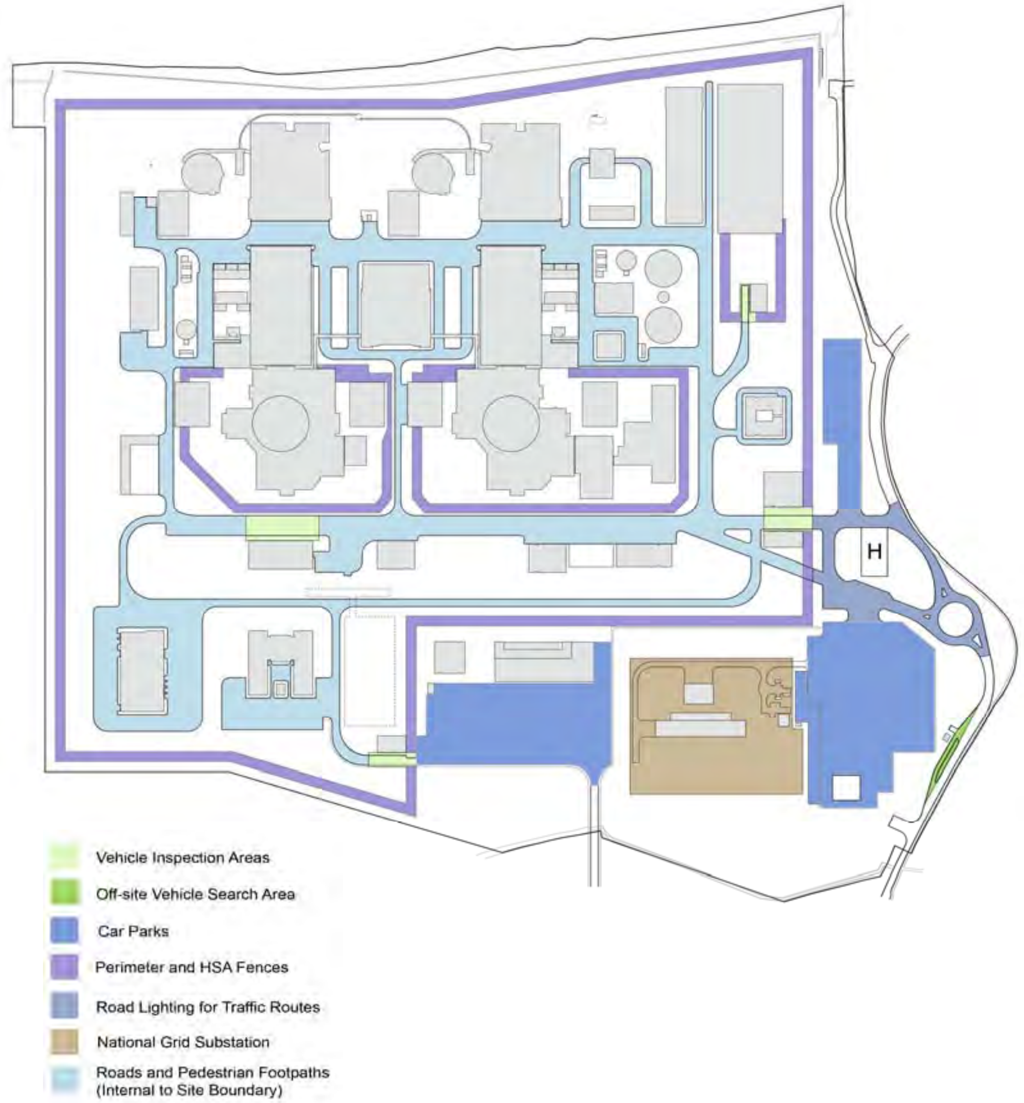
2B.4.3 Details of the indicative proposed lighting are provided on the following drawings (see Technical Appendix):

- HINK-A1-OLS-00-GA-001, Rev 01 – showing external lighting details within the HPC permanent development, including lighting at the southern roundabout but excluding the National Grid Substation.
- 23-SWA-0547750 Rev P1, 23-SWA-0547751 Rev P1 and 23-SWA-0547753 Rev P0 – showing lighting proposals for the National Grid Substation.

2B.4.4 All luminaires specified above would be provided with flat lens with the operating surface parallel to the ground level.

2B.4.5 Wherever applicable, the light fittings should be mounted suitably on the building wall instead of lighting poles.

Figure 2B.11: Operational Lighting (External) within HPC Permanent Development (Indicative)



b) Indicative Description of HPC External Lighting Zones

i. Roads and Pedestrian Footpaths (Internal to Site Boundary)

2B.4.6 Lighting of internal roads and footpaths would be provided with a luminaire type Kingfisher – LED-in Range, 101 Watt, mounted on 8m columns. The proposed layout of the lighting columns is provided in the Technical Appendix.

ii. Car Parks

2B.4.7 Lighting of the car parks would be provided with a luminaire type Kingfisher – LED-in Range, 129 Watt, single or double-mounted on 8m columns. The proposed layout of the lighting columns is provided in the Technical Appendix.

iii. Perimeter and HSA fences

2B.4.8 Lighting of the perimeter fence would be provided with a luminaire type Kingfisher – LED-in Range, 101 Watt, mounted on 8m columns. Lighting of the HSA fences internal to site boundary would be provided with a luminaire type Kingfisher – LED-in

Range, 101 Watt, mounted on 10m columns. The proposed layout of the lighting columns is provided in the Technical Appendix.

iv. Vehicle Inspection Areas

2B.4.9 Lighting of the vehicle inspection areas would be provided with a luminaire type Urbis - ZX3, 250 and 400 Watt, mounted on 8m columns. The proposed layout of the lighting columns is provided in the Technical Appendix.

v. Road Lighting

2B.4.10 Road lighting designed for traffic routes ME3a class lighting would be provided with a luminaire type Urbis – ZX3, 150 Watt and 400 Watt, mounted on 10m columns. Lighting of roundabouts (lighting designed for conflict areas CE2) would be provided with a luminaire type Urbis – ZX3, 250 Watt, mounted on 10m columns. The lamp type would match the existing road lighting.

2B.4.11 Road lighting at the southern roundabout at Wick Moor Drove would be provided with Urbis Sapphire 2 Sealsafe Lanterns, 140 Watt, mounted on 10m columns.

2B.4.12 The proposed layout of the lighting columns is provided in the Technical Appendix.

vi. National Grid Substation

2B.4.13 The proposed luminaires in the National Grid Substation compound are High Pressure Sodium Lamps (SON) which emit light over a moderate band of long wavelengths including a small UV component. Luminaires will be mounted on 6m lighting masts to provide minimum lighting levels of 4lux. For details on external lighting layout, lighting column specifications and lighting levels and contours refer to drawings 23-SWA-0547750 Rev P1, 23-SWA-0547751 Rev P1 and 23-SWA-0547753 Rev P0 in the Technical Appendix.

2B.4.14 Subject to final luminaire selection, National Grid's proposed external luminaires (floodlights and road lighting lanterns) should emit 0% of light above horizontal. To ensure this, it is therefore recommended that the luminaires are installed as per the manufacturer's instructions maintaining an angle of zero degrees to the horizontal plane.

2B.4.15 Lighting levels at 50m from the fence line are as shown on the attached lighting drawing no 23-SWA-0547753 Rev P0 (see Technical Appendix).

2B.4.16 Lighting within the substation will only be activated when:

- the security system is triggered; or when
- emergency work is taking place during the hours of darkness. Predominately repair work and routine maintenance works are planned for daylight hours.

2B.4.17 Due to the proximity of a key bat corridor along the Green Lane, lighting levels at the southern edge of the National Grid Substation area should be zero based on calculated levels as shown on the attached drawing no 23-SWA-0547753 Rev P0 (see Technical Appendix).

2B.5 Summary

2B.5.1 The lighting strategy has been designed to meet objectives outlined for the operational phase of the HPC proposed development and minimise potential lighting impacts on key lighting receptors identified following the analysis of the environmental context for the proposed development.

2B.5.2 The operational HPC development would require lighting within the HPC permanent development area to ensure a safe working environment for all activities, compliance with planning requirements and meeting key standards and statutory requirements.

2B.5.3 The proposed HPC operational lighting strategy:

- complies with planning requirements, meets key standards and statutory requirements and provides a safe working environment;
- is designed to light levels appropriate for the operational site;
- locates the significant sources of lighting away from sensitive receptors, such as residents of nearby settlements or key bat corridors and minimises lighting impact on these key receptors;
- includes luminaires with shields and baffles to limit light spill onto sensitive areas;
- includes lighting columns of a minimum height required for safe operation;
- includes controls to avoid unnecessary illumination;
- includes full cut-off luminaires to prevent upward light and minimise light pollution;
- considers the choice of energy-efficient luminaires which provide enough illumination to safely undertake operational activities while limiting their impact on lighting receptors; and
- contains light sources appropriate for use and the identified environmental considerations.

2B.5.4 The HPC operational lighting strategy has been designed to mitigate lighting impact on the receptors identified in section 2B.2 in line with the relevant legislation, British Standards, policy and guidance. **Table 2B.1** summarises how the strategy aims to mitigate the impact of operational lighting on key lighting receptors.

2B.5.5 The relevant technical chapters of the ES assess the significance of environmental impacts based on the information provided in this strategy.

Table 2B.1: Lighting Mitigation

Receptor	Mitigation measure
Residents of Wick, Shurton, Burton and Knighton and Doggetts farm	Existing and proposed landform including planting, Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation providing screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.
Users of PRoW in the vicinity of the site	Existing and proposed landform including planting, Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation providing screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.
Bristol Channel	Using controls to avoid unnecessary illumination beyond work areas.
Intertidal area	Using controls to avoid unnecessary illumination beyond work areas.
Hinkley Point County Wildlife Site	Existing and proposed landform and screen planting. Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation contribute to screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.
Areas of farmland around the site	Existing and proposed landform and screen planting. Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation contribute to screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.
Key bat corridors	Minimising UV light content. Maintaining buffers between sensitive bat corridors and luminaires. Minimising light spill onto key bat corridors. Existing and proposed landform including planting, Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation providing screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.
Quantock Hills AONB and Mendip Hills AONB	Directing lights downwards. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas. Compliance with Dark Sky policy and relevant British Standards. Lighting designed to Environmental Zone E1 standard.
Exmoor National Park	Directing lights downwards. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas. Compliance with Dark Sky policy and relevant British Standards. Lighting designed to Environmental Zone E1 standard.
Area of outstanding scenic interest	Screening bund along the north-western boundary of the HPC development site. Green Lane ridge and rolling landform, strong hedgerow field pattern, and off-site mitigation contribute to screening. Reducing upward light and using controls to avoid unnecessary illumination beyond work areas.

TECHNICAL APPENDIX

Schedule of Lighting Design Criteria

The lighting design criteria for each functional area of the permanent development site are scheduled together with the particular constraints for each area.

The areas are defined as follows:

- Power Station Operational Areas – Permanent facility comprising of all areas necessary to operate the power station.
- Roads and Car Parks – Roads and car parks within the development area together with interfaces to the public roads. The categories of the roads interfaces will be dependent on the assessment of the average daily traffic (ADT).

Definitions

The following symbols are used in the design criteria schedules:

- E_m – maintained Illuminance (lux) on reference surface taken as ground level
- U_0 – Minimum Illuminance Uniformity
- GR_L – Glare Rating limits
- R_a – Minimum Colour Rendering Index

Power Station Operational Area

Area	**Power Station Operational Area**
Applicable Standard	BS EN 12464-2:2007 Lighting of Workplaces Part 2 Outdoor Work Places

Lighting Requirements for areas, tasks and activities in accordance with:

Table: Power Plants

Area, task or activity	Em	U0	GRL	Ra
Pedestrian movements within electrically safe areas	5	0.25	50	20
Inspection Areas	50	0.4	50	20
Servicing Areas	100	0.4	45	40

Lamp options	Metal Halide, LED
Specific Constraints	Light spill to foreshore area to comply with Environment Zone E1.

Roads and Car Parks

Area	**Roads and Car Parks in the Development Area**
Applicable Standard	Applicable Standard BS EN 12464-2:2007 Lighting of Workplaces Part 2 Outdoor Work Places

Lighting Requirements for areas, tasks and activities in accordance with:

Table: General Circulation Areas at Outdoor Workplaces

Area, task or activity	Em	U0	GRL	Ra
Pedestrian movements within electrically safe areas	5	0.25	50	20
Regular Vehicle Traffic	20	0.4	45	20
Pedestrian passages, vehicle turning	50	0.4	50	20
Medium Traffic Parking Areas	10	0.25	50	20

Lamp options	Metal Halide (low UV), LED, High Pressure Sodium
Specific Constraints	Light spill to foreshore area to comply with Environment Zone E1.
	Light spill to bat corridors to comply with Environmental Zone E1.
	Lamps to have low UV emissions adjacent to bat corridors.

Area	**Roads Interfaces to Public Roads**
Applicable Standard	BS 5489 -1:2008 CoP for Design of Road Lighting Part 1 Amenity Areas

Table: Lighting criteria defined in BSEN 13201-2:2003 Road Lighting Part 2 – Performance Requirements

Area, task or activity	Lighting Class	U0
Traffic routes	ME4a, ME3b, ME3a	subject to average daily traffic
Conflict areas	CE2, CE3	subject to average daily traffic

Lamp options	Metal Halide (low UV), LED, High Pressure Sodium
Specific Constraints	Environment Zone E1.

Glossary of Terms

Light Trespass (E_v)	Light emitted by a lighting installation that falls outside the boundaries of the area for which the lighting installation is designed.
Source Intensity (I)	Intensity of the light source in the potentially obtrusive direction measured in candelas (cd).
Luminance (L_b)	Maximum average luminance of the vertical plane of a neighbouring area from direct illumination, measured in cd/m².
Luminance (L_s)	Maximum average luminance of the vertical plane of signs from direct illumination, measured in cd/m².
Upward Light (ULR)	Proportion of the flux of the luminaire that is emitted above the horizontal, when the luminaire is mounted in its installed position and attitude.
Maintained Illuminance (E_m)	Value below which the average luminance on the specified surface is not allowed to fall. Note, it is the average luminance at the time maintenance should be carried out.
Minimum Illuminance Uniformity (U_o)	Ratio of minimum luminance to average luminance on a surface.
Glare Rating Limits (GR_l)	Upper limit of glare by the CIE Glare Rating system.
Minimum Colour Rendering Index (R_a)	Quantitative measure of the ability of a light source to reproduce the colours of various objects faithfully in comparison with an ideal or natural light source.
Curfew	Time during which stricter requirements (for the control of obtrusive light) will apply.

Dusk View 1 – Principal Viewpoint 3 (see ES Volume 2, Chapter 22)

Dusk View 2 – Principal Viewpoint 7 (see ES Volume 2, Chapter 22)

Dusk View 3 – Principal Viewpoint 9 (see ES Volume 2, Chapter 22)

Note: 1. All luminaires specified above are provided with flat lens with the operating surface parallel to the ground level.
2. Wherever applicable, the light fittings shall be mounted suitably on the building wall instead of lighting poles.

SOUTHERN ROUNDABOUT LIGHTING

Lantern Specification

Lantern Detail

Lantern Type : Urbis Sapphire 2 Sealsafe Lantern
Urbis Reference : SAPH2IB/140/CPOT/1963/FG/NEMA/R7035/
: ALC/GR-HV/HZ-VT/105/-30/263561
Complete With: : 140 Watt CPO -TW Lamp
: Nema Photocell
: Harvard Control Gear
: Colour: RAL 7035
: Optical Unit sealed to IP66, comprising:
: Type 1963 Reflector
: Flat Glass Projector
: Matrix Number 263561 (105/-30)

Mounting Details

Height : 10.0 metres
Bracket Length : 1.0 metre
Inclination : ••••
Column Position : As shown

Lamp Details

Lamp Output : 16,500 lumens
Maintenance Factor : 0.76
Optic Tightness Rating : IP66 Sealsafe
Pollution Category : Medium
Cleaning Cycle : 36 months
Relamping Period : 3 years (12,000 hours)
Number of Units : 18
Scheme Number : SP040_1

SHES BOX

(containing Safety, Health and Environmental Information)

In addition to the hazards and risks normally associated with constructing, maintaining and demolishing the structures on this drawing, the following significant risk information should be taken into account when planning and carrying out construction,operation, maintenance and decommissioning work

Buried services, for which records are available, are shown where relevant. However other services may be present and site rules require precautionary measures prior to any excavation. Damaging buried underground services, low voltage (LV) and high voltage (HV) during excavation works. Risk of electrocution from encroachment within safe zone during construction works. Striking of pilons and overhead cables during construction works.

Risk of electrocution when working with live cables, within close proximity to electrified prerimeter security fence and encroachment within safe zones of pylons.

MAINTENANCE (including cleaning)
Lowering of lighting columns for cleaning of luminaires. Lifting of precast concrete lids to cable access troughs. Proximity to electrified prerimeter security fence and encroachment within safe zones of pylons.

DECOMMISSIONING
Dismantling lighting columns from foundation. Lifting of precast concrete lids & cable troughs. Removal of cables from cable troughs. Proximity to electrified prerimeter security fence and encroachment within safe zones of pylons.

NOTES

1. All dimensions are in millimetres unless noted otherwise.
2. Co-ordinates are in metres and relate to site grid.
3. Direction of luminaires to be confirmed

APPENDIX 4A: OPERATIONAL LIQUID DISCHARGES

APPENDIX 4A: OPERATIONAL LIQUID DISCHARGES

Table 4A.1: Operational Liquid Discharges

Substance	Circuit conditioning (kg/yr)	Sanitary waste discharge (kg/yr)	Producing demineralised water (kg/yr)[4]	Maximum 24-hour loading (kg/d)	Maximum annual loading (kg/yr)
Boric Acid	14000	--	--	5630	14000
Acetic Acid	--	--	14	0.1	14
Acrylic acid	--	--	165	1	165
Aluminium	4.9	--	--	1.1	4.9
ATMP	--	--	9100	45	9100
BOD	--	1278	--	3.5	1278
Boron[1]	2448	--	--	984	2448
Chloride	--	--	87100	450	87100
Chromium	7.8	--	--	1.7	7.8
COD	5050	--	--	330	5050
Copper	0.39	--	--	0.08	0.39
Detergents	3200	--	624	270	3824
Ethanolamine	920	--	--	25	920
HEDP	--	--	890	4.5	890
Hydrazine[2]	28	--	--	4	28
Iron	33	--	46000	257	46033
Lead	0.28	--	--	0.06	0.28
Lithium hydroxide	8.8	--	--	--	8.8
Manganese	3.1	--	--	0.67	3.1
Morpholine	1680	--	--	95	1680
Nickel	0.41	--	--	0.09	0.41
Nitrogen as N	10120	1278	--	324	11398
Phosphates	800	--	--	200	800
Phosphoric Acid	--	--	12	0.1	12
Sodium	--	--	52400	855	52400
Sodium polyacrylate	--	--	8030	40	8030
Sulphates	--	--	98400	2000	98400
Suspended solids	2800	1916	88000	875	92716

Substance	Circuit conditioning (kg/yr)	Sanitary waste discharge (kg/yr)	Producing demineralised water (kg/yr)[4]	Maximum 24-hour loading (kg/d)	Maximum annual loading (kg/yr)
Unionised Ammonium (NH_3)[3]	1184	150	--	74	1334
Zinc	5.6	--	--	1.2	5.6

Table Notes:

[1] Boron is calculated by dividing the loading for boric acid (H_3BO_3) by 5.72 to obtain loading of B alone.

[2] 24 hour flow of hydrazine is based on input data from Flamanville EPR.

[3] Unionised ammonia was calculated as 11.7% (annual loading) or 22.9% (24 hour loading) of the total nitrogen flow (assuming all nitrogen was in the form of ammonia, NH_4^+), based on pH =8.11, salinity = 23.3 psu and temperatures of 35.5^oC (annual loading) and 48^oC (24 hour loadings). For the purpose of worst-case assessment of 24 hour loadings it is assumed that only two of the four cooling water pumps are in operation. (see Ref. 18.65 for further detail).

[4] Loadings include discharges associated with desalination and demineralisation units. Desalination plant loading values have been retained to provide bounding conditions in terms of a worst-case discharge scenario.

APPENDIX 4B: OPERATIONAL GASEOUS EMISSIONS

APPENDIX 4B: OPERATIONAL GASEOUS EMISSIONS

Table 4B.1: Operational Gaseous Emissions

Parameter	Value [a]	Units
EDG emissions		
Stack internal diameter	1.0	m
Stack height	30.0	m
Exit velocity	35	m/s
Ambient temperature of discharge gases	375	˚C
SO_2 emission rate	2.93	g/s
NO_x emission rate	30.66	g/s
PM_{10} emission rate	0.80	g/s
CO emission rate	2.41	g/s
SBO emissions		
Stack internal diameter	0.82	m
Stack height	30.0	m
Exit velocity	15.0	m/s
Ambient temperature of discharge gases	515	˚C
SO_2 emission rate	0.40	g/s
NO_x emission rate	6.80	g/s
PM_{10} emission rate	0.19	g/s
CO emission rate	0.57	g/s
Main stack emissions		
Stack internal diameter	3.0	m
Stack height	70.0	m
Exit velocity	0.982	m/s
Ambient temperature of discharge gases	15	˚C
H_2CO emission rate (commissioning)	0.0342	g/s
CO emission rate (commissioning)	0.0320	g/s
H_2CO emission rate (operation)	0.0243	g/s
CO emission rate (operation)	0.0229	g/s
NH_3 emissions		
Ambient temperature of discharge gases	100	˚C
NH_3 emission rate	3.12	g/s

APPENDIX 7A: LEGISLATION, POLICY AND GUIDANCE

APPENDIX 7A: LEGISLATION, POLICY AND GUIDANCE

7A.1 UK Radioactive Waste Policy

7A.1.1 The development of UK policy on radioactive waste management has been an ongoing process since the start of the nuclear industry in the 1940s. Overarching Government policy is set out in the Government White Paper, Review of Radioactive Waste Management Policy Cm2919, as amended (Ref. 7.1). The fundamentals of the policy are that Government would maintain and continue to develop a policy and regulatory framework which would ensure that:

- radioactive wastes are not unnecessarily created;
- such wastes that are created are safely and appropriately managed and treated; and
- they are then safely disposed of at appropriate times and in appropriate ways to safeguard the interests of existing and future generations and the wider environment, and in a manner that commands public confidence and takes due account of costs.

7A.1.2 The White Paper 'Managing Radioactive Waste Safety: a Framework for Implementing Geological Disposal' (Ref. 7.1) sets out the Government's framework for managing higher activity radioactive waste in the long-term through geological disposal, coupled with safe and secure interim storage and ongoing research and development to support its optimised implementation. It also invites communities to express an interest in opening up, without commitment, discussions with Government on the possibility of hosting a Geological Disposal Facility (GDF) at some point in the future.

7A.1.3 The Government updated its policy on the decommissioning of nuclear facilities in 2004 (Ref. 7.2) which stated that new facilities covered by the policy should be designed and built so as to minimise decommissioning and associated waste management operations and costs.

7A.2 UK Disposal Strategy for LLW

7A.2.1 LLW has been disposed of in near-surface facilities at the LLWR in Cumbria for many years. However, the existing capacity of the LLWR is less than the forecast volume of LLW that must be dealt with in the future.

7A.2.2 The UK Government and the devolved administrations of Northern Ireland, Scotland and Wales carried out a review of solid LLW policy in 2007 (Ref. 7.3) and a new policy was announced that sets out a more flexible approach for managing solid LLW in the long-term. The key aim of the policy statement was to provide a high level framework within which individual LLW management decisions could be taken flexibly to ensure safe, environmentally acceptable and cost-effective management solutions that appropriately reflect the nature of the LLW concerned.

7A.2.3 Under the Energy Act 2004, the Nuclear Decommissioning Authority (NDA) is responsible for developing and implementing a strategy and plans for LLW management and disposal. In 2010 the NDA published the UK Strategy for the Management of Solid Low Level Waste from the UK Nuclear Industry (Ref. 7.4). This sets out a strategy which would provide continued capability and capacity for the management and disposal of LLW in the UK, for both the nuclear and non-nuclear industries through:

- application of the waste management hierarchy;
- best use of existing facilities, working more efficiently and potentially extending the life of the existing national repository; and
- development and use of new fit-for-purpose management and disposal routes, so waste producers have more choice in determining and implementing waste management routes.

7A.2.4 The UK LLW strategy is supported by a number of strategic best practicable environmental option (BPEO) studies covering potential alternatives to the LLWR for metallic wastes, combustible wastes and VLLW. These provide a baseline against which any site can undertake an analysis. A key aspect of achieving the strategy is the improved segregation of wastes to enable alternative disposal routes to the LLWR to be used effectively.

7A.3 UK Long-term Waste Management Solution for ILW and Spent Fuel

a) The Committee on Radioactive Waste Management

7A.3.2 Studies into the best disposal options for legacy[1] higher activity wastes (ILW, HLW) and spent fuel have been ongoing for more than 25yrs. In July 2003, the Committee on Radioactive Waste Management (CoRWM) was established by Ministers of the UK Government and devolved administrations to oversee a review of options for managing legacy solid radioactive waste in the UK and to recommend the option, or combination of options, that can provide a long term solution, providing protection for people and the environment.

7A.3.3 CoRWM reported its findings in July 2006 and recommended ‘geological disposal’ as the solution for the long-term storage of the most hazardous legacy radioactive wastes. CoRWM made a total of 15 recommendations to Government (Ref. 7.5). These covered, amongst other topics:

- geological disposal;
- interim storage;
- flexible decision-making;
- research; and
- inviting communities to host a GDF.

[1] The term legacy refers to waste and spent fuel from past and current civil and military nuclear programmes.

7A.3.4 Recommendations 1 and 2, presented below, provided advice to Government with regard to geological disposal of waste and requirements for interim storage prior to the availability of a GDF.

"Recommendation 1: Within the present state of knowledge, CoRWM considers geological disposal to be the best available approach for the long-term management of all the material categorised as waste in the CoRWM inventory when compared with the risks associated with other methods of management. The aim should be to progress to disposal as soon as practicable, consistent with developing and maintaining public and stakeholder confidence.

Recommendation 2: A robust programme of interim storage must play an integral part in the long-term management strategy. The uncertainties surrounding the implementation of geological disposal, including social and ethical concerns, lead CoRWM to recommend a continued commitment to the safe and secure management of wastes that is robust against the risk of delay or failure in the repository programme. Due regard should be paid to:

I. reviewing and ensuring security, particularly against terrorist attacks;

II. ensuring the longevity of the stores themselves;

III. prompt immobilisation of waste leading to passively safe waste forms;

IV. minimising the need for re-packaging of the waste; and

V. the implications for transport of wastes."

7A.3.5 CoRWM's recommendations have been accepted by UK Government for the long term management and disposal of the UK's legacy wastes and have been taken forward in the Managing Radioactive Waste Safely White Paper described previously.

b) CoRWM Position on New Build Wastes

7A.3.6 In its 2006 Recommendations to Government (Ref. 7.5), CoRWM made it clear that it takes no position on the desirability or otherwise of nuclear new build and stated that future decisions on new build should be subject to their own assessment process, including consideration of waste. CoRWM emphasised that its recommendations are directed to existing and committed waste arisings and should not be seen as either a red or green light for nuclear new build.

7A.3.7 On 25 October 2007 Government re-appointed CoRWM with revised Terms of Reference and a predominantly new membership. These state that:

"...The role of the reconstituted Committee on Radioactive Waste Management (CoRWM) would be to provide independent scrutiny and advice to UK Government and devolved administration Ministers on the long-term management, including storage and disposal, of radioactive waste. CoRWM's primary task is to provide independent scrutiny on the Government's and Nuclear Decommissioning Authority's proposals, plans and programmes to deliver geological disposal, together with robust interim storage, as the long-term management option for the UK's higher activity wastes."

7A.3.8 CoRWM has further clarified its position with regard to nuclear new build (Ref. 7.6); a position statement issued by CoRWM in 2010 reiterated that its position on the desirability or otherwise of building new nuclear power stations remains neutral. In March 2010, CoRWM, in its response to Government consultation on the draft National Policy Statements for Energy Infrastructure (Ref. 7.7), also made a number of observations to Government on matters that, in its opinion, should be addressed when considering approval of new nuclear power stations. The observations are wide ranging and include consideration of whether effective arrangements would exist to manage and dispose of waste that would be produced by new nuclear power stations in the UK.

7A.4 UK Disposal Strategy for New Build ILW and Spent Fuel

7A.4.1 The UK Government has stated that, based on scientific consensus and international experience, waste and spent fuel from new nuclear build would not raise such different technical issues compared with nuclear waste from legacy programmes as to require a different technical solution. Government concluded that it would be technically possible, and desirable, to dispose of higher activity waste from new nuclear power stations in a GDF and that such waste should be stored in safe and secure interim storage until a GDF becomes available.

7A.4.2 The National Policy Statement for Nuclear Power Generation (EN-6), Volume II (Ref. 7.8) states:

> *"The Government is satisfied that effective arrangements will exist to manage and dispose of the waste that will be produced from new nuclear power stations. As a result, the IPC should not consider this question. However there may be planning issues relating to the on-site management of radioactive waste which it is appropriate for the IPC to consider as part of the development consent application."*

7A.4.3 EDF Energy have developed its waste and spent fuel management strategy for HPC in accordance with Government policy and guidance and specifically the "waste base case" that Government has set out in their guidance on the Funded Decommissioning Programme to prospective new nuclear operators (Ref. 7.9).

7A.4.4 A key element of this guidance is that the operator should assume that all higher activity wastes should be stored on the site of its generation until a GDF is available.

7A.4.5 The principle of geological disposal is to isolate the waste deep inside a suitable rock formation to ensure that no significant quantities of radioactivity ever reach the surface environment. It is the main option on which the NDA is conducting research for the long-term management of radioactive waste. It is the UK Government's and many other nations' preferred long-term approach.

7A.4.6 Geological disposal is a multi-barrier, multi-phased approach, based on placing wastes deep underground, beyond disruption by man-made or natural events. The UK Government is currently undertaking a process to identify potential sites for a GDF. The approach is based on voluntarism and partnership with local communities, coupled with the use of appropriate site screening and assessment criteria. Overseas experience, particularly from Sweden and Finland, suggests that such an approach is likely to be an effective way of selecting an appropriate and acceptable site.

7A.4.7 The UK Government has invited communities, through the Managing Radioactive Waste Safely (MRWS) White Paper (Ref. 7.5), to express an interest in our taking part in the process that would ultimately provide a site for a GDF. The NDA is the implementing organisation, responsible for planning and delivering the GDF and, as part of this process, would engage with communities and other stakeholders.

7A.4.8 Three local authorities have expressed an interest in entering discussions about the siting process. These discussions are without commitment and are initially about finding out more about what hosting a GDF would mean for a community in the long-term. Partnership working is developing in these communities to help them make a more formal decision about whether to participate further in the process. This process is separate from and is unrelated to the application to build HPC.

7A.4.9 The MRWS White Paper notes that *“Through agreed mechanisms for updating the Baseline Inventory, inclusion of new waste would be taken forward in discussion with host communities as the programme proceeds. Geological disposal facility design activities would consider the necessary features to safely accommodate particular waste types if that proves necessary”*. It is anticipated that the inclusion of waste from new nuclear power stations would follow this process.

a) Radioactive Waste Management Regulation in the UK

7A.4.10 The UK Government's radioactive waste management policy is supported by a regulatory framework that aims to ensure that all radioactive wastes are safely and appropriately managed in ways that pose no unacceptable risks to people or the environment.

APPENDIX 9A: SOCIO-ECONOMIC TECHNICAL NOTE 1: WORKFORCE PROFILE

FOREWORD

EDF Energy is planning to build a new nuclear power station at Hinkley Point near Bridgwater, Somerset, comprising two UK EPR reactor units with an expected output of approximately 1,630MW per unit. The new site, Hinkley Point C (HPC), is to the west of the existing Hinkley Point Power Station Complex. The new power station is based on replicating as much as possible the design for the Flamanville 3 unit in Normandy, France, currently under construction.

EDF Energy undertook a review of the likely workforce required to construct the Hinkley Point C (HPC) Project and associated developments (AD) which was shared with the local authorities in January 2011 and published in draft as part of the "Stage 2 Update" consultation in February 2011. EDF Energy is now producing its final proposals for the site and associated developments and this note updates the previous figures to reflect the minor changes in proposals and phasing since that time.

The aim of this paper is to provide:

- A revised profile which shows the development of the workforce at HPC during the construction period, and a more detailed understanding of the likely job types and skills mix for the earlier contracts to inform the construction skills workforce strategy that is currently being developed by EDF Energy with the local authorities
- An assessment of the current local labour supply; and
- Predicted mix of home-based and non-home-based recruitment to inform the Accommodation and Transport strategies.

The findings of this note have been used to assess the supply of accommodation, the likely demand arising from the non-home-based workers, the resultant accommodation mix, and the subsequent effects on other services (health, education, policing, leisure etc.). These are incorporated into the technical assessment of the scheme and inform the detailed implementation strategies as well as transport and accommodation.

APPENDIX 9A: SOCIO-ECONOMIC TECHNICAL NOTE 1: WORKFORCE PROFILE

9A.1 Introduction

9A.1.1 NNB Generation Company Limited (company number 06937084), part of EDF Energy, is the company that will ultimately make the Development Consent Order application. For the purpose of this document, NNB Generation Company Limited is referred to as EDF Energy.

9A.1.2 EDF Energy is planning to build a new nuclear power station at Hinkley Point near Bridgwater, Somerset, comprising two UK EPR reactor units with an expected output of approximately 1,630MW per unit.

9A.1.3 The new site, Hinkley Point C (HPC), is to the west of the existing Hinkley Point Power Station Complex. The new power station is based on replicating as much as possible the design for the Flamanville 3 unit in Normandy, France, currently under construction.

9A.1.4 EDF Energy undertook a review of the likely workforce required to construct the Hinkley Point C Project and associated developments (AD) which was shared with the local authorities in January 2011 and published in draft as part of the "Stage 2 Update" consultation in February 2011.

9A.1.5 EDF Energy is now producing its final proposals for the site and Associated developments and this note updates the previous figures to reflect the minor changes in proposals and phasing since that time.

9A.1.6 This has involved the updating the workforce histogram, which was based on data from current and previous power station construction projects, more detailed information on likely skills requirements, and a review of the assumptions about the proportion of workers that will be home-based and non-home-based.

9A.1.7 This paper brings together this information, produced by EDF Energy's internal construction team with HDS, the Impact Assessment Unit (IAU) at Oxford Brookes University, and the EDF Energy Construction Workforce Development Team (using MACE's database of construction skills).

9A.1.8 The aim of this paper is to provide:

- A revised profile which shows the development of the workforce at HPC during the construction period, and a more detailed understanding of the likely job types and skills mix for the earlier contracts to inform the construction skills workforce strategy that is currently being developed by EDF Energy with the local authorities.
- An assessment of the current local labour supply.

- Predicted mix of home-based and non-home-based recruitment to inform the Accommodation and Transport strategies.

9A.1.9 The findings of this note have been used to assess the supply of accommodation, the likely demand arising from the non-home-based workers, the resultant accommodation mix, and the subsequent effects on other services (health, education, policing, leisure etc.). These are incorporated into the technical assessment of the scheme and inform the detailed implementation strategies as well as transport and accommodation.

9A.1.10 The focus is on the overall peak construction employment scenario, but the civils peak is also estimated. The estimates for the construction of the main HPC Project are set out in the wider context of all the other cumulative internal elements for the HPC programme i.e. associated development (AD). These are included in **Plate** A9A.1 in Section 2 of this note. In the context of the whole construction project, the AD workforce numbers are low, and peaks occur before the civils work peak and total peak.

9A.1.11 Socio-economic prediction is an inexact exercise, and the predictions and associated mitigation and enhancement measures should be the subject of regular monitoring. An adaptive assessment approach is required, building from the Environmental Statement, through more detailed forecasts for early phases of the scheme and regular monitoring and effective management of impacts over the duration of the project. This note begins the first two parts of that approach by bringing together the best available data for assessment and planning purposes.

9A.2 Labour Demand

9A.2.1 The proposed Power Station at HPC will be a two unit EPR reactor. The EPR is a new design and two single unit reactors are currently under construction in Europe, in France (Flamanville 3) and Finland (Okiluoto). Neither is yet complete.

9A.2.2 The EDF Energy construction team has used two main sources of information to produce workforce assumptions for HPC.

9A.2.3 Firstly, it has reviewed the workforce profiles from EDF Energy's database of previous projects for (non-EPR) two unit reactors, with an 18 month gap between construction of each, to examine the build-up of overall workforce and the relationship between workforce (operatives) build up for each of the two main contract packages – Civils and Mechanical and Electrical (M+E) - to identify an indicative histogram. The overall histogram and the Civils and M+E components (and their timings) are reflected in **Plate A9A.1**.

9A.2.4 Secondly, it has used EDF Energy monitoring data from Flamanville 3 to identify the quantity of workforce (number of hours worked) and make up (between operatives and staff) for the Civils contracts to date, and forecasts to the end of the construction period. The project began in 2007 and the monitoring data therefore covers the years 2007 to 2010. This includes both Civil and (some) M+E contracts. The total number of hours required to build the power station is assumed to be double that for Flamanville and this has been applied to the histogram for the two unit reactors, with the assumption that the M+E contracts will have the same relationships to Civils as on non-EPR reactors. The conversion of hours worked to workforce numbers is based on an assumption of a typical shift pattern of average 8 hour shifts and 21 days per month per worker. This is consistent with the proposed shift patterns set out in EDF Energy's Stage 2 a consultation.

9A.2.5 It is further assumed that staff and management (contractors and EDF Energy combined) are equivalent to just over 25% of total operatives, and that on-site services, security and clerical roles, just over 5%. These assumptions are based on previous experience at Sizewell, Flamanville and other EDF Energy operations.

9A.2.6 We have also assumed that permanent operational employment begins to build up from month 35 (with month 0 being the beginning of the preliminary works) to prepare for the completion of the first unit, to a peak of 900 (700 directly employed plus 200 contracted) at completion of both units. These are early workforce assumptions and may change over time although, as can be seen from the histograms, any changes will not have an effect on overall peaks as the main operational workforce build up is later in the project.

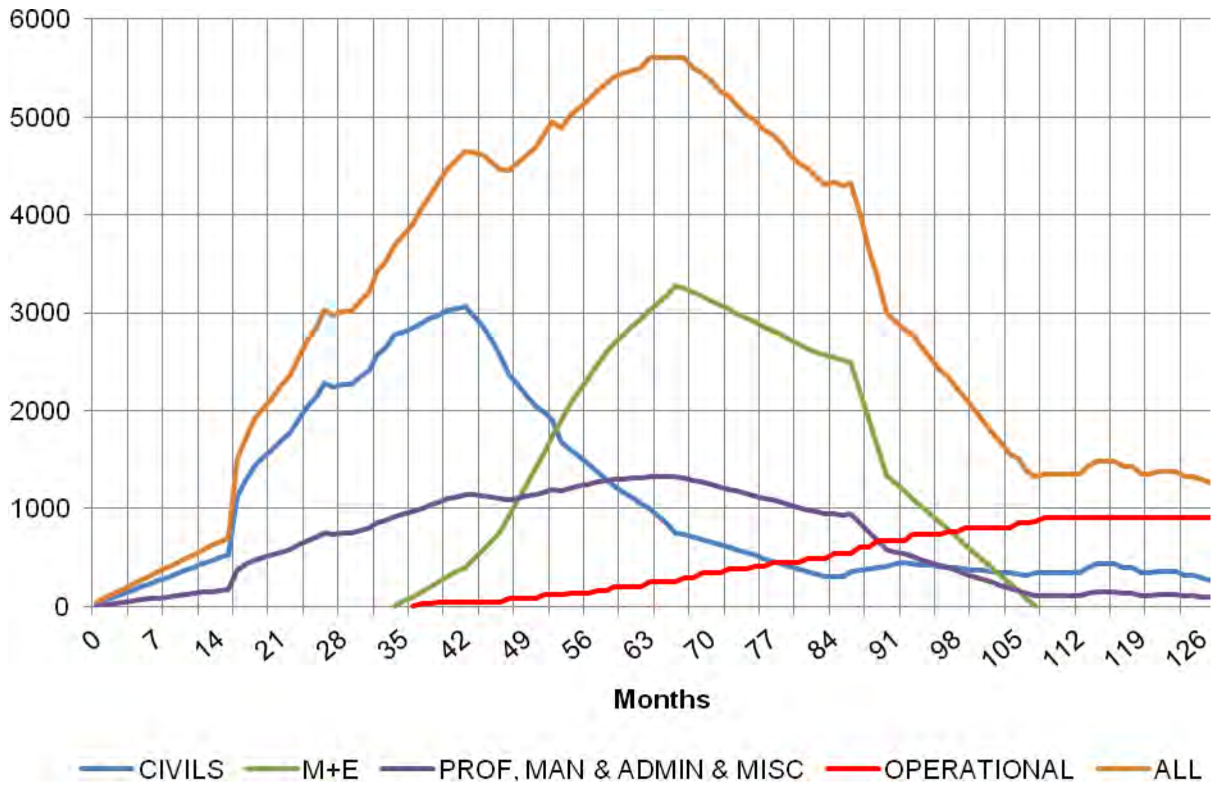
9A.2.7 The data for early works include enabling, remediation, preliminary works and jetty which will be largely completed prior to IPC consent for the main project. They are consistent with the data and assumptions used in the Socio-Economic Chapter of the Environmental Statement for the Preliminary Works application, although they show a "smoothed" build up and also include professional staff as well as site operatives.

9A.2.8 A number of responses to EDF Energy's Stage 2 proposals suggested that it would be useful to take a single overview of total workforce profiles, including those for the proposed Associated developments – namely the Accommodation Campuses, Park and Rides, Wharf, and Cannington Bypass. These have been incorporated into the histogram on the basis of assumptions and proposals that were consulted on in the Stage 2 update consultation. These sites will be completed well before the peak in the Civils and M+E workforces, and any further minor revision will not have a significant impact on the conclusions drawn below.

9A.2.9 Two other particular issues of uncertainty were raised in response to EDF Energy's Stage 2 assumptions – relating to the relative productivity of the British and French construction industries, and the extent to which actual workforce outcomes will depend on the operational approach of chosen lead contractors. In order to test this we have compared the indicative workforce profile from the assumptions above with (commercially confidential) workforce histograms submitted by the five companies bidding for the Civils contracts. This analysis has confirmed that both the peak workforce number and the phasing of the workforce is in line with proposals submitted by the contractors.

9A.2.10 **Plate A9A.1** below, shows the combined histogram which brings together the implications of these assumptions. It identifies a combined "Civils" peak of 4,650, and a combined M+E and overall peak of 5,600. The numerical breakdowns are set out in **Table A9A.1** as key points for identifying peak workforce impacts on labour supply and consequently on accommodation. These assumptions give labour force numbers at key points in the project to ensure impacts can be assessed. Overall numbers of people working on the site over the lifetime of the project are likely to be significantly higher, with a likely range of 20,000 to 25,000 people.

Plate A9A.1: HPC Construction Labour Demand Curve — Estimated Workforce Numbers



Source: from EDF Energy estimates (Jun 2011)

Table A9A.1: HPC: Peak Disaggregated Labour Demand Requirements

	Civils Peak (Month 43, Jan '15)		Overall Peak (Month 64 to 68, Oct '16 to Feb '17)	
	%	Number	%	Number
Civil Operatives	66%	3,070	18%	990
M+E Operatives	9%	400	54%	3,030
Operational Staff	1%	50	4%	250
Staff and Management	19%	900	19%	1,050
Site Services, Security & Clerical	5%	240	5%	280
All	100%	4,660	100%	5,600

9A.3 More Detailed Skill Categories

9A.3.1 **Table A9A.2** sets out broad skill categories based on information from potential civils stage contractors, Cogent (the sector skills Council) (Ref. 9A.1) and on data from the Sizewell B (SZB) construction monitoring study for both civils and M+E stages. (Ref. 9A.2).

Table A9A.2: Main skill categories for construction operatives – drawing on information from construction of Sizewell B/COGENT

Civils Work Stage (operatives)
Timber/formwork
Concrete/cement/masons
Drivers/crane operators/labourers
Reinforced steelwork/erectors
Scaffolders
Welders
Civil works labourers/semi skilled
Others
Mechanical and electrical works stage (operatives)
M+E labourers/semi-skilled
Welders – special metals
Welders – steel
Boiler makers; pipe-fitters
Fitters
Electricians; electro-mechanical fitters
Instrumentation
Cable pullers

9A.3.2 The skills mix will have consequent impacts on the assumptions about home-based and non-home-based splits (and therefore total demand for accommodation) and accommodation demand by type.

9A.4 Skills Model

9A.4.1 In order to plan effectively for the early stages of the construction programme the EDF Energy Construction Workforce Development (CWfD) team has been working on a “bottom up” model, which takes a more detailed view of the early contract packages so that work can be undertaken with partners to plan for effective skills and recruitment measures. This makes the essential link between the assessment model described above, which has been used for planning purposes, and the specific actions required to maximise employment for residents of the local districts and Somerset, which EDF Energy and partners have a shared interest in and commitment to achieving.

9A.4.2 The CWfD team model uses existing project information combined with evidence taken from previous projects and models to build up an indicative picture of labour inputs for each project within the programme. The methodology has information provided by potential main contractors project and planning experience and expert consultation to validate the results and ensure that they are as representative as possible at this early stage of the planning process. It is consistent with the overall workforce assumptions on AD, Civils and M+E contracts as described above.

9A.4.3 There is an element of estimation and assumption in the model which may be improved upon significantly as the finer details of the project are reviewed and agreed. Each project within the model has its own time scale, works phasing, cost and labour profile. Different labour coefficients have been used that reflect the differing nature of the work under construction across all associated developments and the main site. Each project is overlaid onto master programme timeline, which aggregates the labour requirement on individual projects and provides an overview of the overall programme as a forecast of total employment.

9A.5 Outputs: Early Years

9A.5.1 The outputs from the model provide a useful indication of the employment profiles across various occupation groups and the workforce as a whole. It has been used here to provide an indication of the proportions, occupations and skills sets that will be required on the programme during the first two years of the build phase. This includes Associated Development works and the start of the main Civil works at HPC. Forecasts exclude detailed breakdowns of the labour required for the site preparation works (Months 1 to 16).

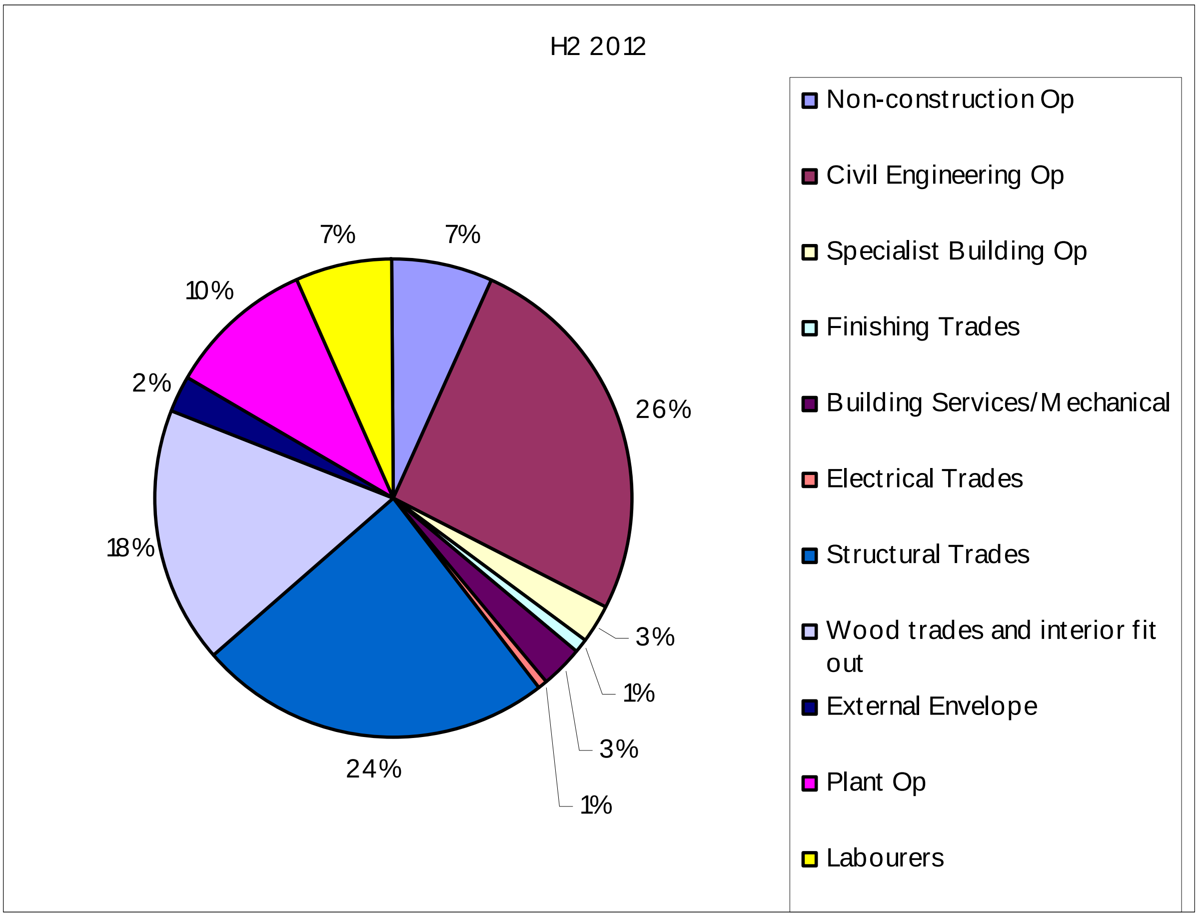
9A.5.2 The forecasts provide indicative volumes and proportions of occupations that will be expected across the programme in 11 broad occupation and skills groups. These are represented using illustrative 6 month breakdowns of the workforce. This allows the model to show the changing proportions of different occupations within the workforce at different points in time as the overall programme progresses.

9A.5.3 The detailed occupational groups shown in **Plate A9A.2:** Months 17 to 22, **Plate** A9A.3 and **Plate** A9A.4, are described in Annex 2.

9A.6 Months 17 to 22 – Main Civils Contract Plus Associated Development

9A.6.1 In the initial six month period of the main programme, it is anticipated that up to half of all construction workers are likely to drawn from civil engineering and structural trades. At this time, the workforce is expected to expand rapidly. There is also a large cohort of wood trades and plant operatives, which will be associated with formwork carpentry and civil engineering preliminary work.

Plate A9A.2: Months 17 to 22



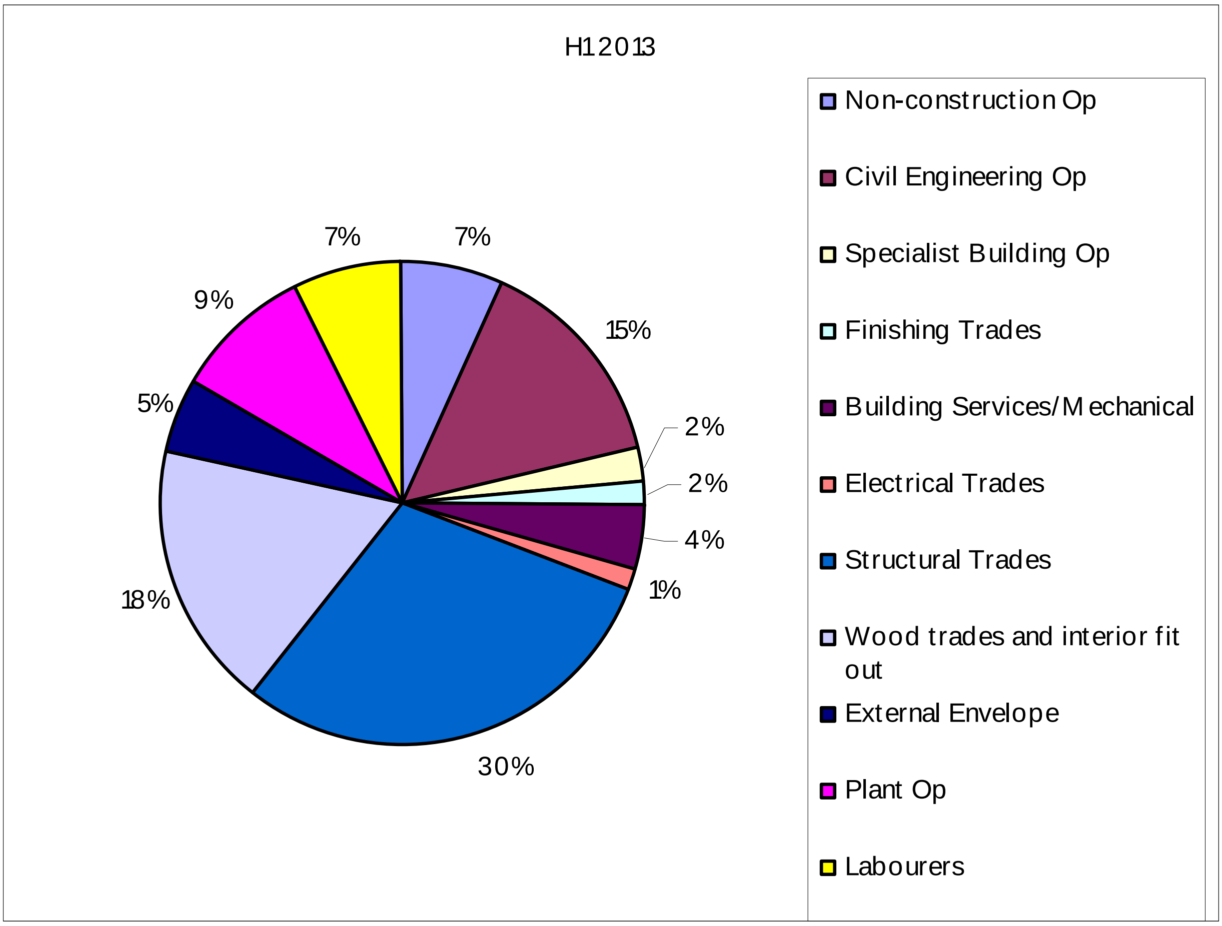
Source: EDF Energy CWfD Model

9A.7 Months 23 to 34

9A.7.1 As the project starts to mature, the numbers in the workforce grow steeply. Within the overall workforce, the numbers of civil engineering operatives will increase but their relative proportion within the overall workforce is predicted to decrease, as structural trades, such as reinforcing bar fixers, increase in prominence.

9A.7.2 Wood trades and plant operatives increase in number but remain at a similar percentage of the workforce as in Period 1. These workforce patterns are to continue to the end of the period.

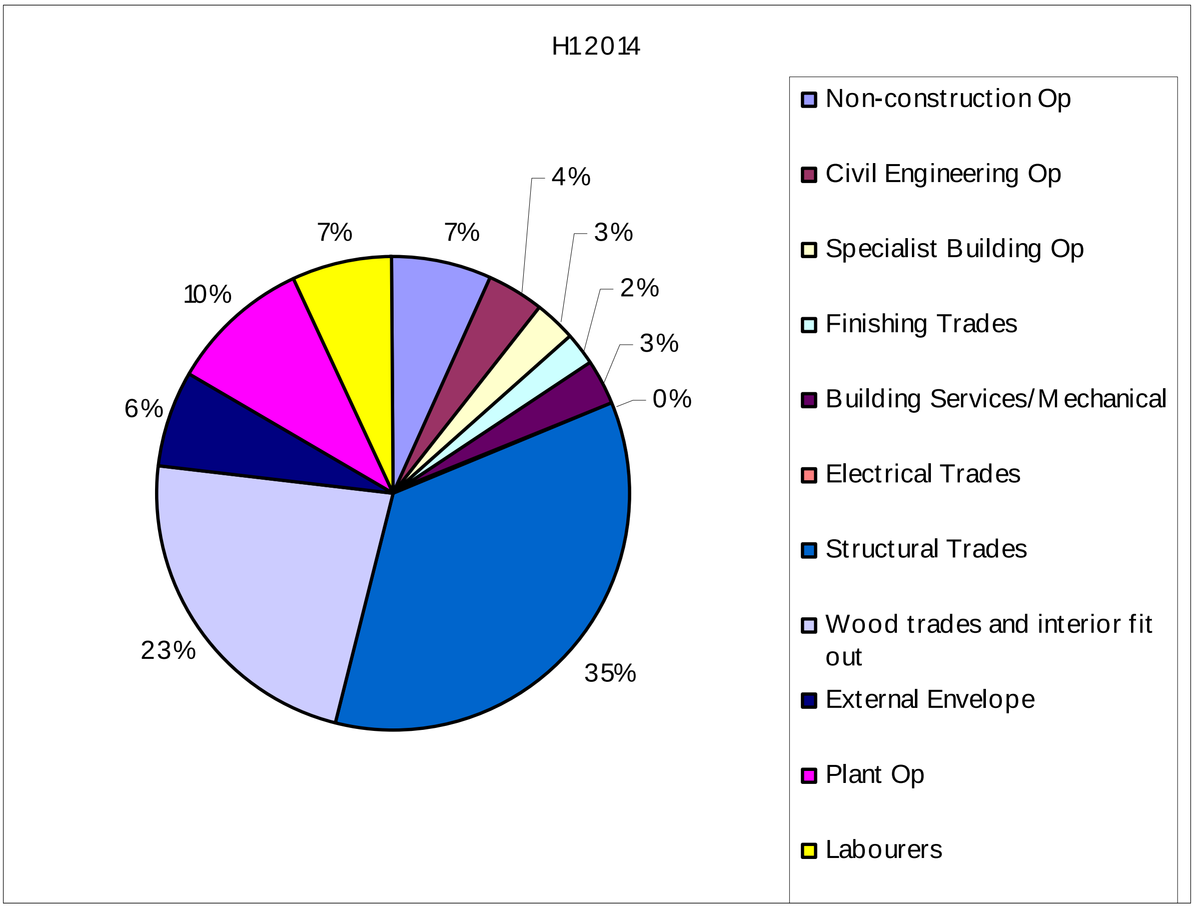
Plate A9A.3: Months 23 to 34



Source: EDF Energy CWfD Model

9A.7.3 By May 2015, it is anticipated that the main AD and preliminary works will be complete and the major civil engineering works will be the dominant project at HPC. The model reflects this, indicating a high proportion and correspondingly large numbers of structural and wood trades within the workforce.

Plate A9A.4: Months 35 to 40



Source: EDF Energy CWfD Model

9A.8 Future Use of Skills Information and Forecasting

9A.8.1 It is a core operating philosophy of EDF Energy that all skills and employment interventions that are put in place to support the construction of HPC will be demand-led, dynamic and flexible. This is to ensure that at all times the offer will align with the needs of EDF Energy, HPC contractors and the wider local economy during the build.

9A.8.2 In order to achieve optimal impact from its employment, skills and training interventions it will be essential for the programme to be intelligence-led and evidence-based, through the effective utilisation of labour forecasts, work package analysis, contractor engagement and broader labour market intelligence.

9A.8.3 These will continue to be developed and supplied by the EDF Energy Workforce Development Team. Skills gaps and requirements will be identified with sufficient time for specific provision and appropriate funding mechanisms to be designed and programmed in advance.

9A.9 Labour supply

a) 90 Minute Construction Daily Commuting Zone (CDCZ)

9A.9.1 In order to assess whether the assumptions about the sources of labour are reasonable, we need to assess the supply of labour from within the home-based and non-home-based workforce. The first step is to confirm the definition of the home-based area/CDCZ and then the split between the home-based and non-home-based workforce.

9A.9.2 The determination of the CDCZ impact area involves consideration of a number of factors which affect workers willingness to commute daily to the site. These include travel allowances for construction workers, general studies of construction workforce mobility and monitoring of previous projects.

9A.9.3 The Construction Industry Joint Council (CJIC) agreement (Ref. 9A.3) sets out national standards for pay and conditions for workers on major building and infrastructure sites in the UK. The current agreement, which took effect in June 2008, sets out rates for daily travel and fare allowances. These are currently payable on a sliding scale based on the distance travelled, up to a maximum of 75 kilometres (c.47 miles).

9A.9.4 A study for the UK DTI and ECITB (IFF and University of Warwick, 2005) (**Table** A9A.1) shows that a proportion of UK and SW region construction workers will travel to work for distances over 50 miles on a daily basis. Indeed it is estimated that 11% of SW construction workers travel more than 50 miles to work daily. (Ref. 9A.4).

9A.9.5 Monitoring studies of the construction of Sizewell B also show actual local recruitment extending to a 50 miles/90 minutes commute (Glasson and Chadwick, 1995). A 90-minute commute zone was also agreed for the assessment in the late 1980s of the previous proposal for Hinkley Point C. (Ref. 9A.5).

9A.9.6 Discussions with local stakeholders at the Socio-Economic Workshops in 2009 and 2010 reinforced these determinants with local knowledge and experience and it was concluded that the 90 minute area remained a reasonable assumption.

9A.10 Labour Supply: Districts, Somerset and CDCZ

9A.10.1 **Table A9A.3, Table** A9A.1 and **Table** A9A.5**,** show local (CDCZ, and Somerset) labour supplies in the construction sector in roughly similar proportions to national and regional supplies. It is important to distinguish between data which includes self-employed and that which does not. Self-employment is very important in the construction sector. **Table A9A.3** shows approximately 48,000 workers (employed) in construction trades in the CDCZ in 2008, of whom about 9,000 were in Somerset. **Table A9A.4** suggests these figures could be even higher.

9A.10.2 In addition, there were about 39,000 people unemployed in the CDCZ in July 2011, with about 7,000 in total in Skilled Trades and in Process, Plant & Machine Operations. A further 10,500 are in the elementary occupations category. **Table** A9A.4 shows that 4,200 people are seeking jobs in construction trades, with about two–thirds seeking skilled jobs and one-third seeking unskilled/ semi-skilled jobs. About 20% of those seeking construction jobs are based in Somerset.

9A.10.3 The detailed occupational breakdowns set out in Section 3.2 are compatible with those set out in Annex 2 and used in the skills model described in Section 2.3 above. This suggests that, for the Civils stage there is a reasonable “fit” with the local labour market with the HPC labour demand representing only a small proportion of the available labour force. The next iterations of the workforce modelling will identify any pinch points and also training requirements which might be necessary to convert generic skills e.g. in carpentry, to the specific requirements of a major infrastructure project e.g. formwork carpentry. This will inform the Construction Workforce Development Strategy. Overall, the general conclusion is that there is a significant and relevant supply of labour in the CDCZ and in Somerset on which HPC can draw.

Table A9A.3: Employment in Construction and Related Activities 2008 (Ref. 9A.6)

Area	Construction Sector (SIC45)	Of which: civil engineering (SIC45.2)	Related Technical Services (SIC74.2)

Table A9A.5: Occupations Sought by Unemployed Claimants: Construction Related Occupations, July 2011 (Ref. 9A.7)

Occupation sought (selected occupations)	Sedgemoor, Taunton Deane and West Somerset	Somerset	90 Minutes CDCZ
Engineering professionals: science & engineering technicians	35	85	520
Skilled mechanical & electrical trades	55	110	570
Skilled construction & building trades	165	300	1,555
Construction Operatives (semi-skilled)	15	35	200
Elementary construction occupations (un-skilled)	125	245	1,380
TOTAL	405	770	4,225

Source: Office for National Statistics, monthly claimant count data. Figures are based on the following SOC 2000 occupational categories which are regarded as relevant to the construction phase of Hinkley Point development: 21.2 – engineering professionals;31.1 – science and engineering technicians; 52.1 – metal forming, welding and related trades; 52.2 – metal machining, fitting and instrument making; 52.4 – electrical trades; 53.1 – construction trades; 53.2 – building trades; 81.4 – construction operatives; 91.2 – elementary construction occupations.

9A.11 Home-based and non-home-based recruitment

9A.11.1 Previous research has shown that the potential for home-based recruitment is very much influenced by the skill level involved, with the percentage local recruitment being higher the less skilled the job. **Table A9A.6** sets out predictions for levels of local recruitment, informed by:

- Power station workforce category requirements.
- Recent information (on civil works) from potential contractors.
- The availability of local supply.
- Comparative information from other UK power station projects and also from Flamanville 3.

9A.11.2 Flamanville 3 has achieved about 45-50% home-based recruitment from La Manche department in the Civils phase. This area has a population of about 500,000, which is similar to the population of Somerset, but which is only about 20% of the population of the HPC CDCZ. It should be noted that such comparative figures at both Sizewell B and at Flamanville 3 do include an element of mitigation/'policy on', with the objective to support recruitment. (NB - Annex 1 provides a comparative analysis of the potential for home-based recruitment between Sizewell B and the proposed HPC, which shows that the demands on home-based supplies of construction workers are well within the margins that were achieved at Sizewell B).

9A.11.3 Analysis shows that, for example, with relatively small levels of demand for Site Services and Clerical jobs (e.g. 240 at civils peak; 280 at total peak), low skill requirements, relatively high wages, and large availability of labour supply (both employed and unemployed), there should be few problems in meeting the high proportions of home-based recruitment which have been the norm for this category of employment on other power station construction sites. In contrast, the much higher levels of demand for professional and managerial staff (900 at civils peak and 1,050 at total peak), the high skill requirements, the tendency for the developer and main contractors to second staff from 'head office', and the relative shortage of such skills in the CDCZ (including in Somerset in particular) indicate likely low proportions of home-based recruitment, although possibly at the upper end of recent such project experience.

Table A9A.6: Ranges for Total Local Recruitment at Peak Construction from Other UK Nuclear Power Station Studies

Employee Category	Range from previous studies	Specific case of Sizewell B peak construction from monitoring data
Site services and security operatives	90-100%	96
Clerical staff	90-100%	33*
Professional staff	2-20%	33*
Civil Operatives	45-75%	61
Mechanical and electrical operatives	35-50%	38

Source: Power Station Studies, Impact Assessment Unit

** - Combined monitoring category at Sizewell B*

9A.12 Estimates of Potential Home-Based Recruitment

9A.12.1 **Table A9A.7** provides broad estimates of potential home-based recruitment from within the 90-minutes CDCZ at civils peak and at total peak. All the percentages are mid-points of a range of up to +/- 10%. The commentary in the table provides a summary of the analysis from the previous sections of this note.

9A.12.2 These estimates are then applied to the disaggregated labour demand requirements for HPC construction main project, as set out in **Table A9A.1**. **Table A9A.8** and **Table** A9A.9 provide estimates of the mid-points of the home-based (CDCZ) and non-home-based splits for the civils peak and the total peak respectively.

9A.12.3 The higher home-based percentage for the civils peak reflects in particular the greater propensity for home-based recruitment for the civil operatives' category. Conversely, the lower percentage for the total peak reflects in particular the lower propensity for home-based recruitment for the more skilled and larger number of M+E operatives.

9A.12.4 For both peaks it is estimated that there will be little or no difference in recruitment to the other categories, with the exception that the peak civil operatives' stage may be lower than for the total peak by virtue of the civils' peak demand on certain skill groups. The application of the +/- 10% ranges would give home-based recruitment figures of 1,770 (38%) to 2,140 (46%) for the civil works peak and 1,740 (31%) to 2,120 (38%) for the total peak.

Table A9A.7: Estimates of Potential Home-Based Recruitment Percentages from CDCZ: Civils Peak And Total Peak Construction (All % Are Mid-Points Of Range Of Up To +/- 10%)

Construction Workforce Category	Predicted HB recruitment (civils peak)	Predicted HB recruitment (total peak)	Commentary
Site services, security and clerical	90	90	Recruited from service sector, less skilled jobs, relatively low numbers needed, and considerable potential from unemployed
Professional staff (EDF Energy and contractors)	15-20	15-20	Other extreme of skill requirement. May be case for a higher HB rate than previously used (10%), informed by contractors' data and unemployment figures in relevant categories. NB: contractors' and EDF Energy clerical staff are included in site services, security and clerical category. Estimated CDCZ recruitment is less than 1% of CDCZ employment in relevant categories
Civil works operatives	45-50	50	Guidance from SZB indicates a 40:60 skilled: semi/unskilled split. There is likely to be reasonable availability from employed and unemployed in CDCZ—enhanced by training. Location Quotients for civil works trades are around national norms, except for scaffolders and plant operatives Which are slightly lower.
M&E work operatives	35	30	Guidance from SZB indicates a 75:25 skilled: semi/unskilled split. Home-based availability from employed and unemployed in CDCZ will be much tighter than for Civils —especially for specialist skilled jobs. Also M&E numbers peak is the overall peak. But Location Quotients for M&E trades are around national norms, except for electricians. Still some HB potential—for some skilled jobs and especially for less skilled jobs.
Operational staff (permanent occupations)	50	50	Draws much on previous operational recruitment patterns at Hinkley and Sizewell

Table A9A.8: Home-based and Non-Home-based Labour at the Proposed Hinkley Point C: Civil Peak Construction (rounded numbers) (all % are mid-points of range of up to +/- 10%)

	Total	Home-based		Non-Home-Based	
		%	Number	%	Number
Civil Operatives	3,070	46%	1,420	54%	1,650
M&E Operatives	400	34%	140	66%	260
Operational staff	50	50%	30	50%	30
Staff and management	900	15%	140	85%	770
Site services, security and clerical	240	90%	220	10%	20
All (including AD & Prelims)	4,660	42%	1,950	58%	2,730

Note: Numbers may not add due to rounding

Table A9A.9: Home-Based and Non-Home-based Labour at the Proposed Hinkley Point C: Overall Peak Construction (rounded numbers) (all % are mid-points of range of up to +/- 10%)

	Total	Home-based		Non-Home-Based	
		%	Number	%	Number
Civil Operatives	990	50%	500	50%	500
M&E Operatives	3,030	30%	910	70%	2,120
Operational staff	250	50%	130	50%	130
Staff and Management	1,050	15%	160	85%	890
Site services, security and clerical	280	90%	250	10%	30
All (including AD & Prelims)	5,600	34%	1,900	66%	3,700

9A.12.5 As implied by **Table A9A.8** and **Table A9A.9,** the proportion of the total workforce which will be home-based (i.e. already resident in the 90 minute area) will vary over the period of the development, with a higher proportion at the outset, which then reduces as the project moves towards its peak, and increases again towards completion as the permanent workforce grows – all of whom will ultimately live in the area. The overall number of local opportunities will however continue to increase as the project moves towards peak (representing a slightly lower proportion of an increasing number of jobs). This is illustrated in **Plate A9A.5** and **Plate A9A.6**.

9A.12.6 This phasing of jobs provides partners with the opportunity to increase local workforce proportions in the later stages by recruiting local people in the earlier stages for lower skilled jobs and helping them to develop their skills and move between contractors and different types of contract throughout the construction period. This approach has been a successful feature of large scale construction projects and depends on a concerted effort at the early stages to produce high quality skills information, and tailored programmes to address local needs.

9A.12.7 On the basis that such programmes are implemented it is estimated that of this home-based workforce, over two-thirds will be Somerset residents. At the civils peak it is anticipated that Somerset residents will make up 31 per cent of the total workforce, falling to 23 per cent at overall peak. On average over the lifetime of the project Somerset workers are likely to make up at least 25 per cent of the workforce. When applied to the total number of workers over the lifetime of the project set out in para 2.1.10, this suggests at least 5,000 Somerset residents will work at Hinkley in the construction phase.

Plate A9A.5: Hinkley C - Indicative Home-Based Workforce (Proportion of Total)

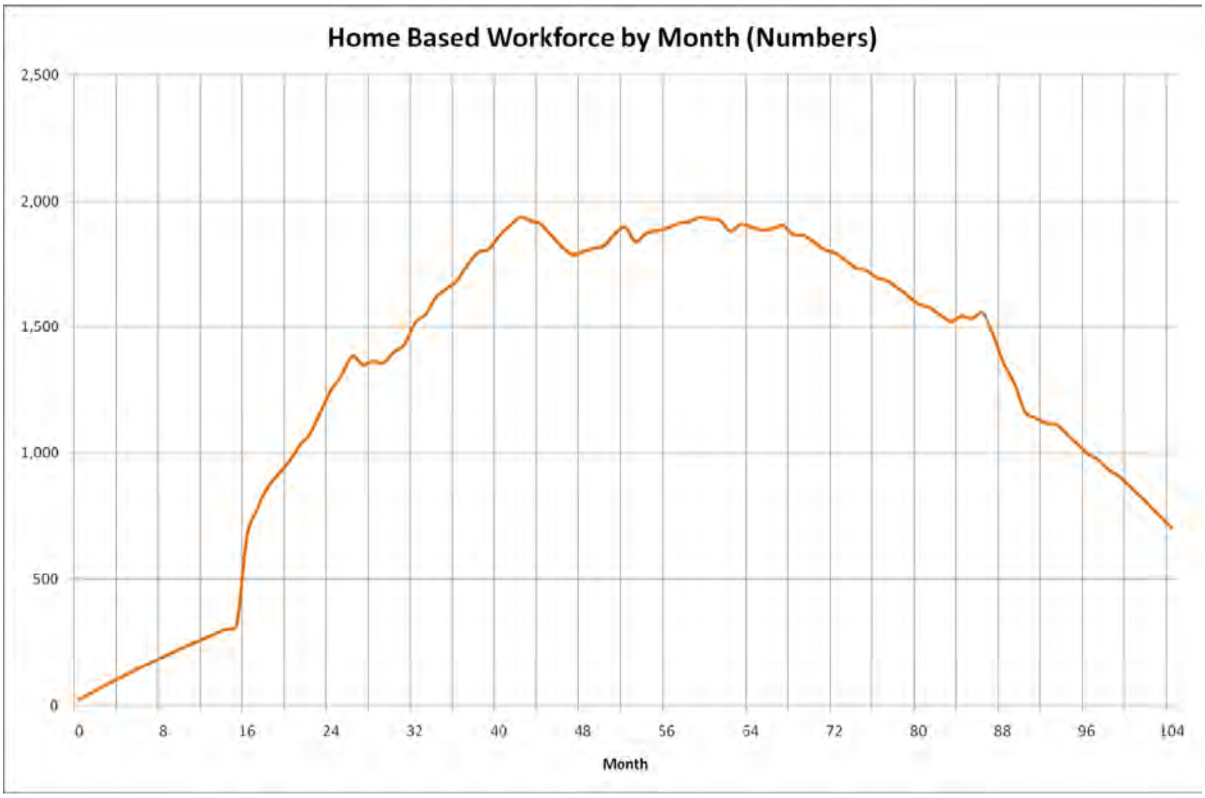
Plate A9A.6: Hinkley C - Indicative Home-Based Workforce (Number)



Source: IAU Assumptions/EDF Energy/HDS

Use of Workforce profile

9A.12.8 The workforce profile described above has been used to underpin the assessment of the socio-economic impacts of the construction phase of the HPC development. It has been brought together with EDF Energy's strategy for accommodating construction workers, and the transport ("Gravity" model) which identifies the likely locations, within the CDCZ, where the workforce will be resident. This information has been used to inform the assessment of the likely overall population impacts and impacts on public services and local communities.

9A.12.9 The information has also been used to help plan for EDF Energy's Construction Workforce Development Programme, which will begin operation with the implementation of the early works contracts, to maximise the opportunities for residents of the immediate districts and Somerset more generally. The skills forecasts will be updated throughout the project, and informed by an on-going system of monitoring.

ANNEX 1: SZB/HPC COMPARISON

The CDCZ for the Sizewell B development was based on the 1984 definition of Travel-to-Work Areas (TTWAs), covering an area within 90mins of the power station site. Using 1991 Census data, it is possible to determine the proportion and total number of residents employed in the construction industry (Standard Industrial Classification; SIC) – this is a scaled-up number derived from a 10% sample of all residents of these TTWAs. (Ref. 9A.8).

Table A9A.10: Construction Workforce Population Distribution at Sizewell B

Census 2001				
1984-based TTWA	**Total Population (10% Sample)**	**People employed in Construction (10% Sample)**	**Total Population**	**Construction Employees (scaled-up)**
Clacton	7,647	235	65,580	2,015
Colchester	20,069	841	160,302	6,718
Harwich	2,182	33	17,594	266
Beccles and Halesworth	4,741	181	38,323	1,463
Bury St. Edmonds	7,086	246	58,622	2,035
Diss	3,745	139	31,268	1,161
Great Yarmouth	10,158	348	82,616	2,830
Haverhill	3,248	129	25,859	1,027
Ipswich	23,291	813	187,919	6,560
Lowestoft	7,898	281	65,394	2,327
Newmarket	8,060	307	64,782	2,468
Norwich	29,957	1,118	247,146	9,224
Sudbury	5,190	221	41,736	1,777
Thetford	6,250	208	50,186	1,670
Woodbridge and Leiston	6,085	264	48,788	2,117
TOTAL	145,607	5,364	1,186,115	43,656

Source: Census 1991

This indicates an overall proportion of 3.68% of all people in the Sizewell CDCZ that were employed in the construction industry, equating to around 43,656 people. This compares to the current (2001) assessment for the HPC 90-minute CDCZ of 3.14% of all residents employed in construction. The HPC CDCZ is based on Local Authorities, and **Table A9A.11** outlines the total number of people, and those residents employed in the construction industry in 2009. (Ref. 9A.9).

Table A9A.11: Total Population and Residents Employed in Construction Sector

Census MYE (2009) / Annual Population Survey (2009)		
Local Authorities	**Total Population**	**Residents employed in Construction**
Bath and North East Somerset	177,700	6,900
Bristol, City of	433,100	11,800
East Devon	132,700	6,500
Exeter	118,800	6,100
Mendip	108,700	3,400
Mid Devon	76,000	2,600
North Devon	91,500	2,900
North Somerset	209,100	8,300
Sedgemoor	112,100	2,900
South Gloucestershire	262,200	11,200
South Somerset	158,600	4,700
Taunton Deane	108,700	2,400
Teignbridge	126,900	5,800
West Dorset	96,500	4,000
West Somerset	35,400	1,600
Newport	140,400	4,700
TOTAL	2,388,400	85,900

Source: ONS Mid-Year Population Estimates 2008; ONS Annual Population Survey 2009

Table A9A.12 summarises and compares the labour pools for the Sizewell and Hinkley C CDCZs, indicating that a similar proportion of a larger pool for Hinkley were employed in construction industries in 2001 compared to the Sizewell CDCZ in 1991, both in terms of total population and working-age economically active population. Being a larger population, therefore, the Hinkley CDCZ has a significantly larger number of construction-employed residents:

Table A9A.12: Comparison of Sizewell B and Hinkley Point C CDCZ Characteristics

	Hinkley Point C CDCZ	Sizewell CDCZ
Total Population	2,388,400	1,186,115
Total Population (16+, Economically Active)	1,163,200	651,350
Residents Employed in Construction	85,900	43,656
% of all Residents Employed in Construction	3.60%	3.68%

As **Table A9A.12** shows, the potential workforce within 90 minutes of HPC is 100% bigger than the equivalent for Sizewell B. This suggests that higher levels of local labour should be easier to achieve at HP C than they were at Sizewell B. Local employment was in fact higher at Sizewell B than has been assumed in the assessments for HPC. At Sizewell B, the proportion of labour drawn from within the CDCZ fluctuated over the course of the construction phase. In the first quarter of construction it was 55%, it then rose to 65% in Q2 before declining to around 50% in Q6 and remaining there until Q16 at which point it declined over a further five quarters to 40%. It remained around 40% until the final year of construction when it was between 35% and 38%.Residents of the CDCZ made up at least 40% of the construction workforce for the entire construction period except the final year, when they made up no less than 35%.

ANNEX 2: EMPLOYMENT GROUPS AND SECTORS

Table A9A.13: Employment Groups and Sectors

GROUP	TRADE
	Lifts
	Mechanical
Building Services/Mechanical	Plumbing inc Sanitary Ware
	Rail Workers
	Utilities - Comms
	Utilities - Electrics
	Utilities - Gas
	Utilities - Water & Drainage
	Groundworkers (Civils) incl piling
	Tunnellers
	Asphalters/Road Layers
Civil Engineering Op	Landscapers/Pitch/Track Contractors
Electrical Trades	Electricians (inc. FAs & Comms)
	Brick/Block layers
	External Walls
	Scaffolders
	Glaziers
External Envelope	Roofers
	Screeders
	Carpet Layers
	Decorators
	Fittings, Seats Signage
Finishing Trades	Tilers (Floor & Wall)
Labourers	General Operatives
	Prelims - Site Admin
	Prelims - Caterers
	Prelims - Cleaners
	Prelims - Security
	Prelims - Transport
	Logistics - Waste Operatives

APPENDIX 9B: SOCIO-ECONOMIC TECHNICAL NOTE 2: DEMOGRAPHIC BENCHMARKS

FOREWORD

EDF Energy is reviewing the potential impacts of the development of Hinkley Point C (HPC). As part of this process it has produced a revised assessment of the likely workforce profile, set out in an accompanying technical note (HPC Socio-Economic Technical Note 1: Workforce Profile) which has been agreed with the local authorities.

This note builds on that assessment, to consider the possible demographic make-up of that workforce, and illustrative examples of where the workforce might live

The note uses:

1. Benchmark data on the profile of the UK construction workforce, which gives an illustration of the potential profile at Hinkley;

2. More detailed data from the socio-economic technical assessment, and the experience of previous major construction projects to address specific concerns such as family profiles and disabilities; and,

3. Illustrative data from the “gravity model” which shows where the non-home based workforce might live based on assessments of accommodation availability and EDF’s accommodation proposals.

Socio-economic prediction is an inexact exercise, and the predictions and associated mitigation and enhancement measures should be the subject of regular monitoring. An adaptive assessment approach is required, building from the Environmental Statement, through regular monitoring and effective management of impacts over the duration of the project.

APPENDIX 9B: SOCIO-ECONOMIC TECHNICAL NOTE 2: DEMOGRAPHIC BENCHMARKS

9B.1 Demographic Breakdowns of the Construction Workforce

a) Approach

9B.1.1 Technical Note 1 sets out estimates of the numbers, likely phasing, and types of workers required to construct HPC. It also, through an assessment of the labour market and drawing on experience of other major construction projects, estimates the likely proportions of the workforce who already live within 90 minutes of the site and will commute daily (the home-based workforce), and those who will move into the area (defined as a 60 minute radius), mostly on a temporary basis, to work on the construction project (the non-home based workers).

9B.1.2 These overall numbers are the starting point for assessing the likely impacts of the construction workforce. In order to be able to have a more detailed understanding of likely impacts it is necessary to have a more refined picture of the people who will comprise this workforce, particularly the non-home-based workers.

9B.1.3 This paper considers a range of source data on the construction labour force in the UK to identify potential demographic breakdowns of this workforce, particularly for those groups covered by the Equalities Act 2010 (Ref. 9B.1) for which data is available, and which will form part of the Equalities Impact section of the Socio-Economic Assessment for the HPC scheme. These are:

- age;
- sex;
- disability; and
- race.

9B.1.4 Data is not available for other Equalities groups identified in the Act but they will be considered in a qualitative way, if appropriate, in subsequent assessments.

9B.1.5 In addition to these demographic breakdowns, this report also considers the extent to which workers are likely to bring families to the area, as this could have some very specific impacts on public services.

9B.2 Source Information

9B.2.1 We have sought to identify the most up to date, comprehensive and relevant datasets to undertake our analysis, and have particularly sought to find information that is broken down to at least regional level, to be able to explore local dimensions. The key data-sources used include.

9B.2.2 Census Data from the 2001 Census (Ref. 9B.2) – although this is now nearly ten years old it remains the most comprehensive single dataset on age and gender characteristics, although where we have used this information we have sought to validate using more up to date information.

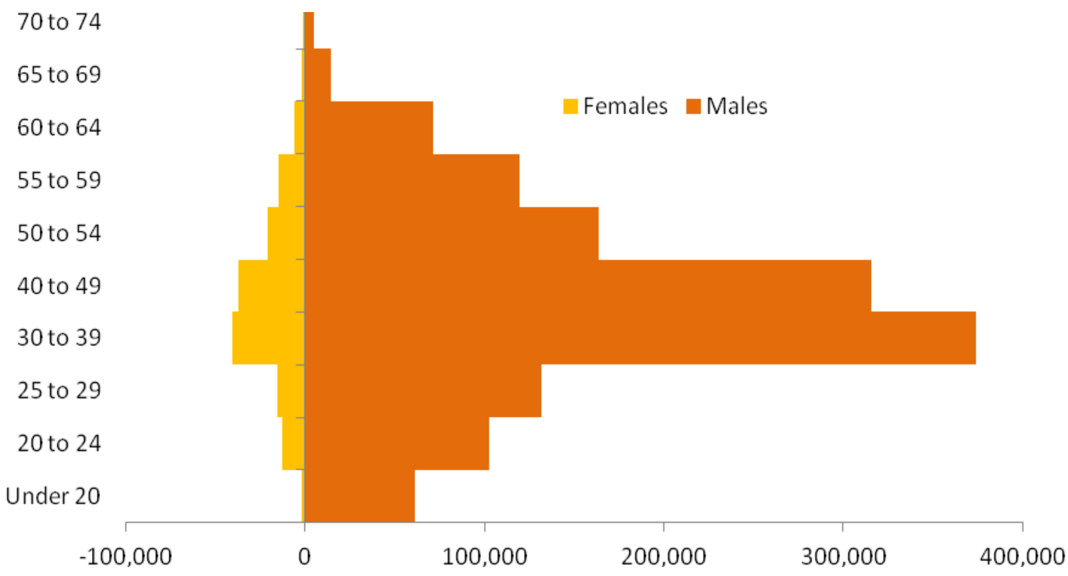
9B.2.3 Annual Population Survey/Labour Force Survey – which provides the most comprehensive recent data (June 2010). Because this is a sample survey it becomes less reliable at the local level, and for the purposes of this report we have therefore used data for the south-west region. We have used both directly available data from the National Online Manpower Information Services Database (NOMIS), and also from secondary sources; (Ref. 9B.3).

9B.2.4 Reports bringing together primary data from elsewhere such as those produced by the Skills and Intelligence Learning Module (SLIM) at the Southwest Observatory, (Ref. 9B.4) the Construction Skills Network (CSN) (Ref. 9B.5), monitoring of major construction projects including Sizewell B, and academic research.

a) Age and Gender

9B.2.5 The 2001 Census gives a comprehensive overview of the age and gender structure of the UK construction industry. **Plate A9B.1** below shows the split between age ranges and males and females. It demonstrates that the construction workforce is overwhelmingly male and in the 20 to 49 age range.

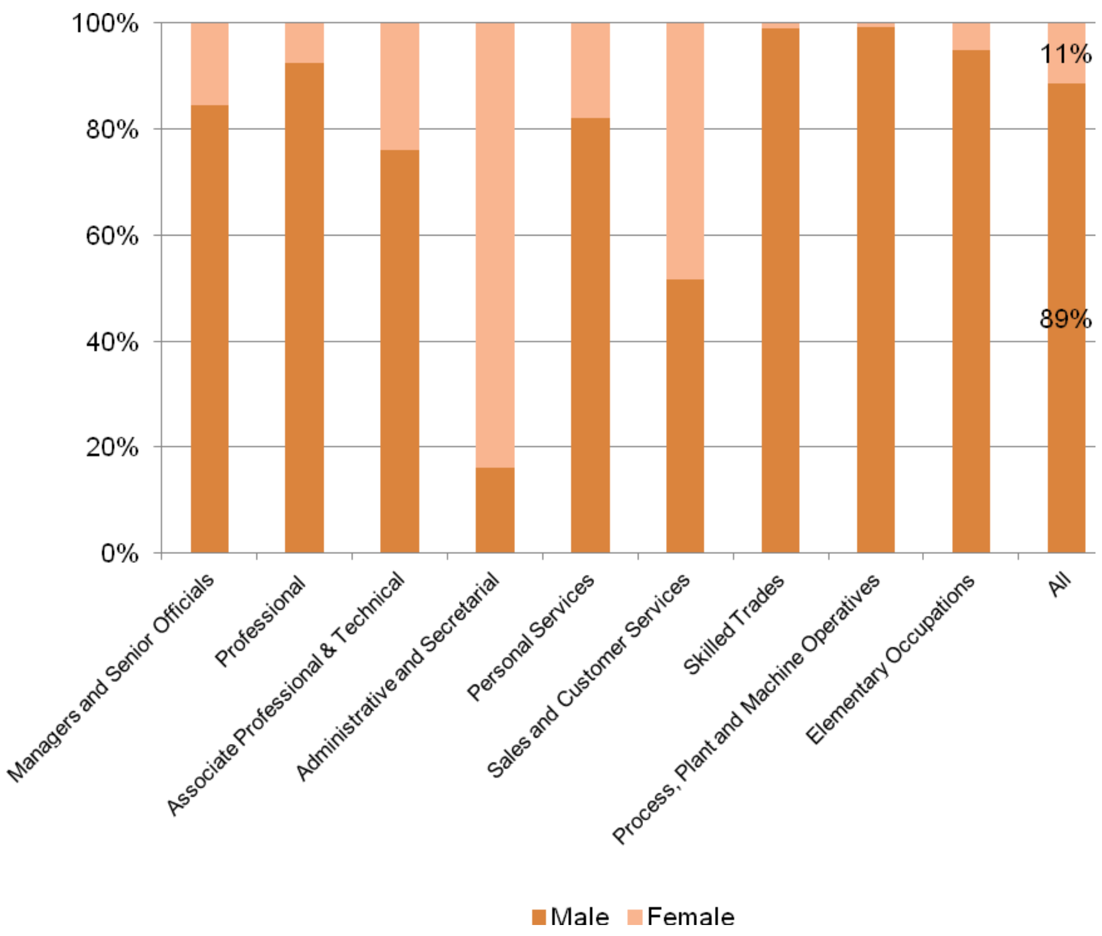
Plate A9B.1: Age and Gender Breakdown: Construction Sector (2001)



Source: Census 2001, Quod

9B.2.6 More recent data from the Annual Population Survey (2009/10) confirms that these proportions have not changed in the intervening decade. **Plate A9B.2** shows the gender breakdown by job type within the construction sector as well as the proportions overall. This shows that while women make up the majority of the workforce in Administrative and Secretarial Occupations (of which there will be a number at HPC (see Technical Note 1), and between 10 and 20% of professional and managerial positions, the on-site operative occupations (skilled trades, elementary and operatives) are male dominated. As these dominate the sector as a whole, just fewer than 9 out of 10 workers in the construction sector are men.

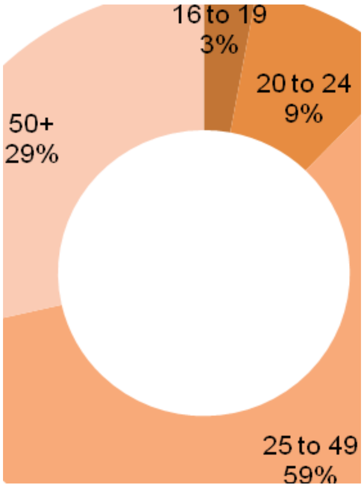
Plate A9B.2: UK Construction Workforce by Gender 2009/10



Source: Annual Population Survey 2009/10

9B.2.7 **Plate A9B.3** shows the age breakdown of the workforce from the same survey which confirms the broad age split from the Census. The recent Gibson Report, reviewing productivity and skills in the UK Engineering Construction Industry (Ref. 9B.6) notes the predominantly male workforce, and the ageing of the UK engineering construction workforce - with about 65% of the current workforce over the age of 40. This covers the more skilled roles involved in designing, engineering, constructing and maintaining the process plant.

Plate A9B.3: UK Construction Workforce by Age 2009/10



Source: Annual Population Survey 2009/10

9B.2.8 These gender and age breakdowns are fairly consistent across all of the datasets that we have reviewed and have changed little, if at all, over time (Briscoe (1995) shows no change in proportion of women working in the sector between 1990 and 2003). We have therefore applied them to the peak non-home-based workforce of 3,700, taking into account job types and skill levels, from Technical Note 1. The rounded benchmark age and gender numbers are set out in **Table A9B.1** below. We believe that these provide a reasonable basis for an assessment of public services impacts relevant to these dimensions.

Table A9B.1: HPC: Age and Gender Benchmarks

Age Group	Male	%	Female	%
Under 35	1,180		130	
35-49	1,220		140	
50+	920		110	
TOTAL	3,320	90%	380	10%

Source: Quod

b) Disability

9B.2.9 There are a number of definitions of disability, which means that there is no single source of data for identifying benchmarks in the construction industry.

9B.2.10 The Labour Force Survey (now the Annual Population Survey) used the definition from the Disability Discrimination Act (Ref. 9B.7) and asked whether people have a health problem or disability that limited their day to day activities or the paid work they could do. The most recent (2004) data identifies 13.7% of the construction workforce having a disability, and 16.5% in the South West.

9B.2.11 Other sources have identified lower proportions. These include:

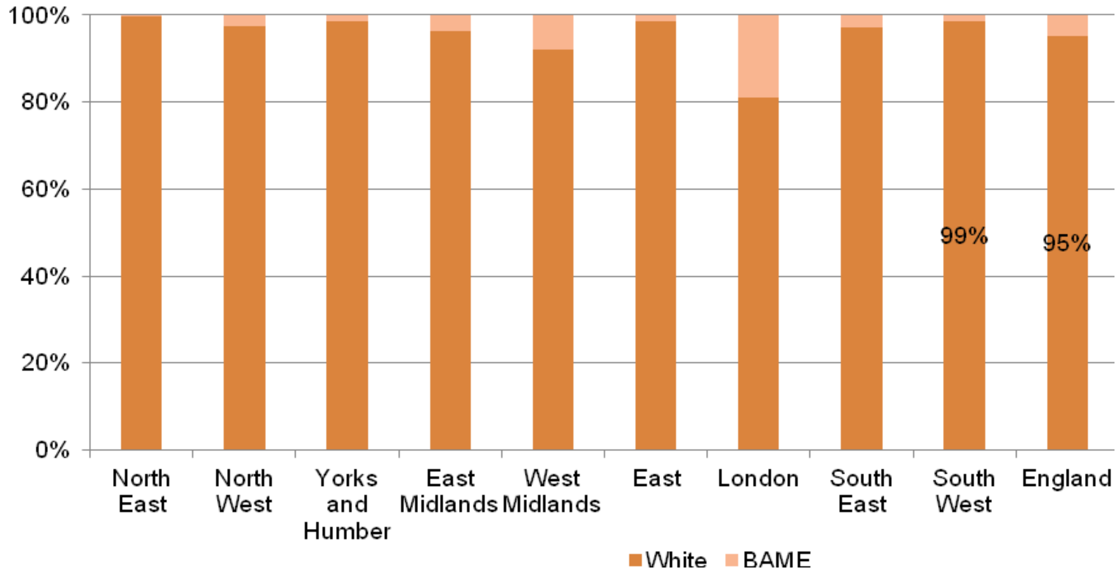
- London Development Agency/Mayor of London (2007), t*he Construction Industry in London and Diversity of Performance*. From the 2001 Census, this report identified 6.6% of employees in manual construction trades in London as people with LLTI (limiting long term illnesses). (Ref. 9B.8).
- *Construction Industry Council (2009)*, *Gathering and reviewing data on diversity within the construction professions*. This report identified a range of from 8 to 15% of the construction workforce, across UK regions, with some form of disability. (Ref. 9B.9).
- Olympics Delivery Authority (ODA) (2010), Employment and Skills Update. This bulletin identified a project target benchmark of 3% of workforce from people with disabilities, but in the published figures for September 2010 the project only achieved 1.2% despite considerable efforts to achieve the benchmark. (Ref. 9B.10).

9B.2.12 Given the diversity of definitions it would not be appropriate, on this basis, to identify a benchmark of construction workers with disabilities for HPC. EDF Energy and its contractors and sub-contractors will ensure that they meet the requirements of the Disability Discrimination Act (2004 and other dates) and the Equalities Act to ensure that disabled people are treated equally.

c) Race, Nationality and Ethnicity

9B.2.13 **Plate A9B.4**, below, shows the ethnic breakdown of the construction workforce in the UK. This shows that the workforce is 95% white in the UK as a whole, rising to 99% in the south-west. London is the only significant outlier with just under a fifth of its construction workforce being from black and minority ethnic communities.

Plate A9B.4: Ethnicity of Employed Construction Workforce 2009/10

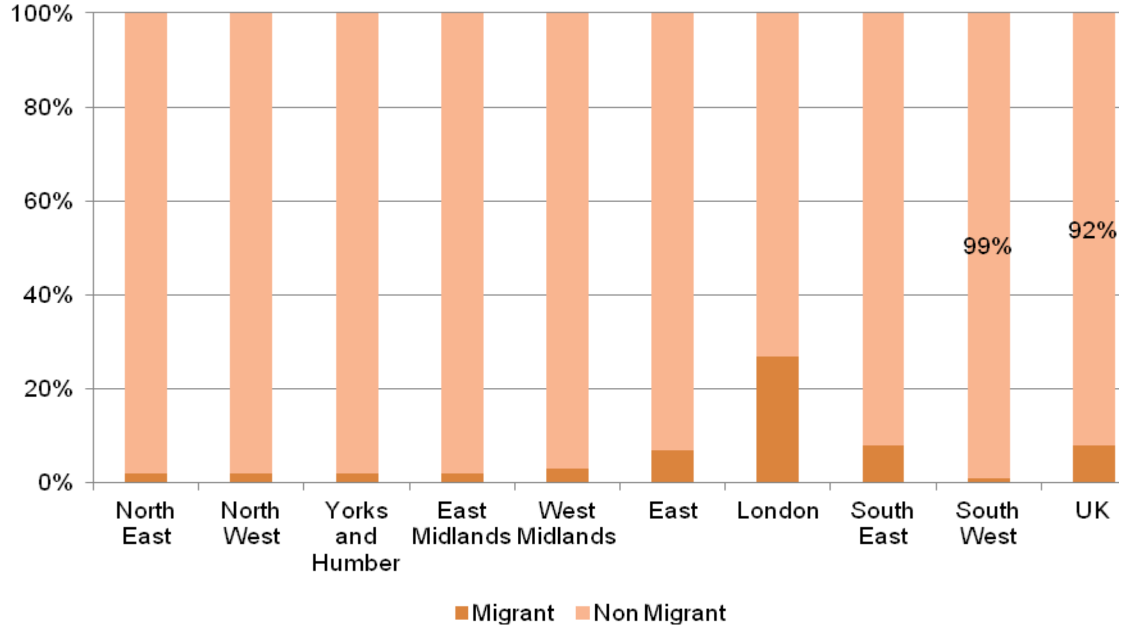


Source: Annual Population Survey 2009/10

9B.2.14 This pre-dominantly white workforce contains within it a range of nationalities. **Plate** A9B.5, below, shows the proportion of the construction workforce that was non-migrant (i.e. UK nationals) and migrant (foreign nationals) in 2008. This shows that the workforce was predominantly British nationals, standing at 92% of the overall workforce, rising to 99% in the south-west. Again, London is the main outlier with over a quarter of the construction workforce being foreign nationals. Of the “migrant” workers around two-thirds are from what is described as the A8 Accession countries, the central and eastern European countries that joined the EU in 2004.

9B.2.15 It would not be appropriate to set a benchmark for ethnicity or nationality of the HPC workforce. All workers at HPC will have a legal right to work in the UK, and all workers will be covered by UK employment law. It should be noted that construction is a “naturally itinerant industry” with workers moving to where the work is available. (Ref. 9B.11) EDF Energy is working with the Local Authorities and other agencies both to maximise jobs for Somerset residents and to ensure that arrangements are put in place to manage the impacts of the entire non-home-based workforce.

Plate A9B.5: UK Construction Workforce: Migrant/Non-Migrant (2008) (Ref. 9B.12)



Source: CSN/BRMB

d) Families

9B.2.16 It is assumed that each non-home-based construction worker taking owner occupied accommodation will be doing so because they are bringing family members to the area with them. It is estimated from previous studies of the construction of Sizewell B Power Station in the 1990s that for each construction worker with a family there will be 1.2 non-construction worker adults, and 0.85 children per family.

9B.2.17 Applying these proportions to the breakdowns in Technical Note 1, suggests there might be a total of up to 500 family-type households at HPC at peak. Further to this, it is estimated that these households would have around 300 school age children in total, around 60% (174) of primary age and 40% (124) of secondary age. In addition there would be likely to be a further 85 children of pre-school age.

9B.2.18 Given the age of this data we have sought to find appropriate comparators to test their current applicability. First, we have sought to identify the extent to which migrant workers have dependent children of school age. Data on this is available from the Worker Registration Scheme, from 2004 to 2007. This covers people from the A8 accession countries described above but, in the absence of other data, we have used this as a proxy for all non-home-based operatives including UK nationals. This shows an average for the South-West of 4.2% of workers having dependent children and 5.7% for the UK as a whole. This is in line with the operatives proportions set out in paragraph 2.18 above.

9B.2.19 We have also sought to validate the assumptions about family size and make up. To do this we have used data from the 2001 Census on “Moving Groups” i.e. those households who have moved into their home in the last year, both within the County and outside. The data allows us to isolate households by age of head of household, so we have calibrated these with the age range set out in **Table A9B.1**. This serves to exclude pensioner households, which might artificially depress the numbers of children is included in the assessment. Using this data we identify an average of 63 children per 100 households, compared to the 85 described in para 1.2.18. They were also broadly split along the same age ranges. This would again seem to suggest that the assumptions are broadly reasonable.

9B.2.20 Discussions are underway with Somerset County Council on the implications of these numbers for education provision and EDF Energy is currently awaiting updated information on schools capacity projections. The section below deals with the potential distribution of the non-home-based workforce, which will be of importance in managing impacts on education and other services.

9B.3 Spatial Distribution of the Workforce

9B.3.1 The spatial distribution of the workforce will be significant for managing the impacts of the incoming population on local areas and services.

9B.3.2 The distribution of the non-home-based workforce will be driven by a number of factors including the scale and location of purpose-built "campus" accommodation by EDF Energy, and the cost and availability of other types of accommodation including "latent", owner occupied, private rented and tourist accommodation. Detailed assumptions about this are contained in EDF Energy's draft Accommodation Strategy and its accompanying technical note. These assumptions have been fed into a Transport "Gravity Model" which then distributes the workforce across the 60 minute zone.

9B.3.3 **Table A9B.2**, below, shows how this workforce is distributed within the 60 minute commuting zone from HPC. This assumes approximately 1,000 campus places in Bridgwater and 500 on site. On this basis just under 2,000 non-home-based workers would be located in Sedgemoor and about 800 in West Somerset.

Table A9B.2: Indicative Distribution of Non-Home-Based Workforce

Area	All Accommodation Sectors
Sedgemoor	1,970
West Somerset	780
Taunton Deane	430
Mendip	75
North Somerset	455
TOTAL	3,700

Source: SBA/EDF

9B.3.4 **Figure 1.1** shows a more "fine grained" distribution of the overall workforce, home-based and non-home based. It shows, perhaps unsurprisingly, that the workforce is likely to be clustered in the main settlements of Bridgwater, Taunton, Burnham, Weston Super-Mare and Minehead.

9B.3.5 **Figure 1.2** shows only the non-home-based workforce in Owner Occupied accommodation – those most likely to have children of school age. This shows a broader distribution which, given the relatively small numbers concerned, doesn't show any major clusters in any single location. This again reflects the findings at Sizewell that families were reasonably spread across the area with noticeable impacts in only one or two locations.

9B.4 Input to Wider Work Streams

9B.4.1 The demographic assessment and benchmarks above are intended to enable EDF Energy and partners to assess potential impacts of the workforce on the local area. It should be noted that the benchmarks are for the "peak" workforce and will not reflect conditions for the full nine years of the construction project. Most of the impacts can be scaled to reflect the non-home based workforce over the construction period as shown in Technical Note 1.

9B.4.2 The information contained in this report has already been presented to the Socio-Economic Task-group, Somerset County Council Education Officers (17 February), the Emergency Services Group (23 February), the Skills Operations Group, (25 February) and Health Task Group, (3 March). It will be also be used for further assessments of impacts on relevant services including the Socio-Economic assessment for EDF's application to the Infrastructure Planning Commission.

APPENDIX 9C: TECHNICAL NOTE 3: SPATIAL DISTRIBUTION OF WORKERS

FOREWORD

This Technical Note:

1. Briefly describes the input datasets to the Gravity Model produced by SBA for ‘home-based’ and ‘non-home-based’ construction workers; and

2. Summarises the modelled spatial distribution of home-based and non-home-based workers, by demographic characteristics.

An accompanying technical note produced by SBA describes the technical inputs into the distribution model, including the application of a distance-decay function and travel-time data.

9C. TECHNICAL NOTE 3: SPATIAL DISTRIBUTION OF WORKERS

9C.1 Assumptions

9C.1.1 Overall, it is assumed that home-based workers will travel a maximum journey time of 90 minutes, also referred to as the CDCZ, and non-home-based workers will travel a maximum of 60-minutes journey time. This includes drive time to the closest park & ride, transfer, and bus journey to site.

9C.1.2 The Gravity Model applies a peak workforce of 5,600 construction employees to the CDCZ, of whom 34% (1,904) would be home-based and 66% (3,696) non-home-based. (Ref. 9C.1)

9C.1.3 Non-home-based workers are assumed to split between the following types of accommodation in the 60-minute area:

Table A9C.1: Accommodation for Non-Home-Based Workers in the 60-Minute Area

Type of Accommodation	Percentage of Workers	Number of Workers
Campus	39%	1,450*
Tourist Accommodation	16%	596
Private Rented	20%	750
Owner Occupied	14%	500
Latent Accommodation	11%	400
Total non-home-based	66%	3,696

** 97% Occupancy*   *Source: HPC Gravity Model*

9C.2 Input Datasets

a) Tourist Accommodation:

9C.2.1 The amount of available tourist accommodation was provided by SWT from their database (Nov 2008).

b) Private Rented Accommodation:

9C.2.2 To provide a distribution of those workers living within private rented accommodation, the number of dwellings within each 2003 CAS ward at the time of the 2001 Census was extracted, and the percentage within the private rented sector identified. This was scaled up based on recent estimates of PRS sector at district-level taken from Strategic Housing Market Assessments undertaken between 2006-8 for relevant districts.

9C.2.3 The SHMA is considered to be the most up to date information on the housing market across the area and reflects the information the local authorities return to central Government for the Housing Strategy Statistical Appendix (HSSA).

c) Owner-Occupied Accommodation

9C.2.4 The Gravity Model is based on the total number of family sized owner-occupied units (defined as houses with three or more bedrooms) in each ward within the 60-minute travel time catchment. This is based on Census data.

d) Latent Accommodation

9C.2.5 In addition to the existing accommodation that is currently accounted for in the gravity model, the refined gravity model now considers latent accommodation. This is additional accommodation that has been offered to EDF Energy in response to adverts placed in November 2009 and again in the Spring of 2011. In addition to private rented properties, this provided a source of ‘latent’ accommodation, i.e. property which had not previously been offered for rent and primarily comprising rooms within people’s houses. As a consequence of these advertisements and ongoing calls to EDF Energy, over 1,500 bedspaces in private accommodation have been registered to date of which over 400 are rooms within people’s houses.

9C.2.6 The responses of the latent accommodation surveys have been used to provide a spatial distribution of this accommodation within the catchment area.

9C.3 Distribution of Home-Based Construction Workers

9C.3.1 Around 34% of peak construction employees are expected to be home-based, living within the 90-minute travel-time CDCZ. The distribution across wards is based on factors including travel-time from the ward to the site, Standard Occupational Classification (SOC) level of the population, and the proportion of 16-74 year olds in work.

9C.3.2 The ward-based distribution of home-based workers across the CDCZ is outlined in **Figure 1.1**.

9C.4 Distribution of Non-Home-Based Construction Workers

9C.4.1 The distribution of construction workers has been assessed on a ward-level basis for the wards within a 60-minute travel distance from the site. The distribution is based on a number of factors relevant to the type of accommodation construction workers would be expected to live in, for example:

- The total number of family-sized owner-occupied units in each ward;
- The total number and estimated vacancy of PRS units in each ward; and
- The total number and occupancy level of tourist bedspaces in each ward.

9C.4.2 **Figure 1.2** shows overall distribution of non-home-based workers in the 60-minute area (with the exception of campus-based workers), 9C.4.3 In order to assess the spatial distribution of non-home-based construction workers by demographic characteristics, it has been considered sensible to split the area into a number of 'ward clusters' as shown on **Figure 1.3**.

9C.4.4 The following table identifies the location of these non-home-based construction workers by 'ward cluster' with accommodation campuses:

Table A9C.2: Non-Home-Based Workers by Ward Cluster

	Accommodation					
Ward Cluster	Non-Home-Based Latent	Non-Home-Based Tourist	Non-Home-Based PRS	Non-Home-Based OO	Campus	Non-Home-Based Total
Bridgwater	137	67	110	108	970	1,392
Burnham and Highbridge	39	201	64	74	-	378

TOTAL	400	596	750	500	1,450	3,696

Source: Quod

a) Demographic Distribution

9C.4.5 EDF Energy has been working with the Councils to agree the evidence base for assessing the likely impacts of the HPC scheme. This has involved the production of a series of Technical Notes. **Technical Note 1** (which has been signed off by the Councils) sets out the overall workforce profile and **Technical Note 2** (which is being reviewed by the Councils) sets out the demographic breakdown of the workforce.

i. Families

9C.4.6 A notional additional population assumption has been made on the location and demographic make-up of families accompanying non-home-based workers.

9C.4.7 Around 500 non-home-based workers will live in family-type households, i.e. with one or more dependents (although not necessarily children). In order to assess the spatial distribution, it has been estimated that each family contains one construction worker, 1.2 non-construction-worker adults and 0.85 children (the age of children has been determined based on the methodology outlined **in Technical Note 2, Section 1.2 - d)**. This is an estimate for peak employment.

Table A9C.3: Non-Home-Based Peak Employment Population Projections, in Owner Occupation by Location

	Owner Occupied	Children		
	Families	Pre-School	Primary	Secondary
Bridgwater	108	18	37	27
Burnham and Highbridge	74	13	26	18

Source: Quod

ii. Age and Gender

9C.4.8 While women make up the majority of the workforce in Administrative and Secretarial Occupations (of which there will be a number at HPC (see Technical Note1), and between 10 and 20% of professional and managerial positions, the on-site operative occupations (skilled trades, elementary and operatives) are male dominated. As these dominate the sector as a whole, just fewer than 9 out of 10 workers in the construction sector are men.

9C.4.9 The recent Gibson Report, reviewing productivity and skills in the UK Engineering Construction Industry (Ref. 9C.2) notes the predominantly male workforce, and the ageing of the UK engineering construction workforce - with about 65% of the current workforce over the age of 40. This covers the more skilled roles involved in designing, engineering, constructing and maintaining process plant.

9C.4.10 The 2001 Census gives a comprehensive overview of the age and gender structure of the UK construction industry. (Ref. 9C.3) **Figure 1.1** in **Technical Note 2** shows the split between age ranges and males and females. It demonstrates that the construction workforce is overwhelmingly male and in the 20 to 49 age range.

9C.4.11 The largest age group in the construction industry are males in their 30s, who make up 25% of the of all construction workers. The next largest group is males in their 40s, at 21%, followed by those over 50 and under 30 who make up around 19% of the industry each. Overall, females make up 10% of the industry and they are fairly evenly distributed amongst the age groups.

9C.4.12 The peak non-home-based workforce has therefore been split accordingly by age and gender. The following table summarises the spatial distribution of construction workers (and partners in the case of those in owner-occupied units) by gender and age:

Table A9C.4: Non-Home-Based Workforce, and Families (in Owner Occupation) by Age and Location

		Male			Female		
	Dependent Children	Under 35	35-49	50+	Under 35	35-49	50+
Bridgwater	82	**449**	**464**	**350**	**81**	**87**	**68**
Burnham and Highbridge	56	**123**	**128**	**96**	**36**	**38**	**30**
Cannington	28	**40**	**41**	**31**	**15**	**17**	**13**

APPENDIX 9D: SOCIO-ECONOMIC TECHNICAL NOTE 4: ACCOMMODATION DATASETS

FOREWORD

This Technical Note:

1. Briefly describes the Gravity Model Approach to distribution of non-home-based workers; and

2. Summarises the approach taken to accommodation datasets, identifying across sectors the location of stock, capacity and vacancy estimates.

An accompanying technical note produced by SBA describes the technical inputs into the distribution model, including the application of a distance-decay function and travel-time data, and describes how the Gravity Model ascribes non-home-based workers to different sectors.

9D. APPENDIX 9D: SOCIO-ECONOMIC TECHNICAL NOTE 4: ACCOMMODATION DATASETS

9D.1 Introduction

9D.1.1 This Technical Note outlines the initial data and processes used to define the accommodation baseline for the socio-economic assessment, and should be read in conjunction with the Accommodation strategy. It highlights the approach to estimating current levels of stock, vacancy rates and occupancy across private rented, tourist, owner-occupied and latent sectors, and how these are applied to the spatial distribution of workers via the Gravity Model to underpin accommodation assumptions.

9D.2 Estimated Accommodation Locations

9D.2.1 The precise location that workers choose to live will be dependent on a number of factors, including their duration of stay, the price of accommodation, access to their permanent homes, proximity to park and ride facilities and the HPC site (via direct buses), and access to amenities such as sport and leisure, and, in the case of families, schools.

9D.2.2 EDF Energy has developed a Gravity Model to estimate the locations of HPC workers – both home-based and non-home-based (Ref. 9D.1). Based on typical travel times for construction workers in the South West, this assumes that people already living in the local area will be willing to travel up to 90 minutes each way in order to work at HPC. Where workers are moving to the local area in order to work on the project, it is assumed that they will want to move closer to the site. Therefore a 60 minute zone has been used to assess the availability of local accommodation. These travel times assume workers are travelling either via the park and ride sites or using direct bus services.

9D.2.3 **Figure 1.1** shows the limit of the 60 minute zone, adjusted slightly to fit electoral ward boundaries. It covers all of the Districts of Sedgemoor and Taunton Deane, most of West Somerset, and parts of North Somerset, Mendip and South Somerset.

9D.2.4 For non-home-based workers, the model has two elements – a weighting based on the amount of accommodation in the area and one based on the distance from the site. The more accommodation there is in an area the more workers are assumed to live there and the shorter the time to the site, the more workers are assumed to work there. This means workers are estimated to cluster in more urban area (where there is more accommodation), especially those with quicker access to the sites. As a result, relatively few workers will be located towards the extremities of the 60 minute zone, especially those which are rural areas with relatively little accommodation.

9D.2.5 A full explanation of the model is set out in **Chapter 10** of the **Transport Assessment**.

9D.2.6 The local authorities have agreed that the Gravity Model is an acceptable method of estimating the spatial distribution of workers, although they have expressed concern that 60 minutes is too long for people to travel on a daily basis and suggested that a 45 minute travel time should be used as a sensitivity test. The effect of this would be to reduce the area over which workers are dispersed from the site and the park and rides.

9D.2.7 The 60 minute zone is more appropriate, for three reasons:

- Construction workers will travel up to 90 minutes for work – the 60 minute assumption therefore already reflects the fact that non-home-based workers will choose to live closer to the site.
- The Gravity Model is already weighted so that areas close to the 60 minute limit are assumed to house relatively few workers.
- There is little difference between the catchment for a 45 minute journey via bus direct to the site and that for a 60 minute catchment via the park and ride sites.

9D.2.8 The central assessment case is therefore based on the 60 minute catchment. This Accommodation Strategy is based on that central assessment case.

9D.2.9 The Environmental Statement sets out sensitivity tests based on higher overall numbers in given locations, and the ability of different types of accommodation to meet the needs of those higher numbers.

9D.2.10 EDF Energy's socio-economic consultants have examined in detail the scope for existing accommodation in Somerset to meet the additional demand created by the project. This has involved careful consideration of the potential scale of accommodation available in four sectors:

- tourist accommodation.
- Private Rented Sector (PRS).
- Owner Occupied Sector (OOS).
- latent accommodation – i.e. accommodation that is either new or not currently counted within the PRS and tourist databases and could, for instance, include renting out a spare room.

9D.2.11 The following main data sources have been used for this analysis:

- Tourist: South West Tourist Board's Accommodation Database and a survey undertaken by Arup on behalf of the local authorities.
- Private rented: Census (for ward level data), estate agents, and local authority data including the Strategic Housing Market Assessment and Housing Strategy Statistical Appendix (HSSA) returns.
- Owner occupied: Census (for ward level data), and local authority data including the Strategic Housing Market Assessment and HSSA returns.
- Latent: EDF Energy's office in Bridgwater has created a database that captures responses from local people and businesses wanting to supply accommodation to HPC workers. This was informed, in part, by two newspaper surveys asking local

people to contact EDF Energy if they had accommodation they would like to make available to EDF Energy's workforce.

9D.2.12 The remainder of this section sets out how much accommodation of each type is expected to be available across the 60 minute zone.

9D.2.13 The following sections outline, for each accommodation sector, the approach taken to estimate the quantity and location of bedspaces, seasonal availability, and estimated vacancy levels.

9D.3 Tourist Accommodation

9D.3.1 There is a substantial local supply of tourist accommodation in the Somerset area. **Table A9D.1** provides information on supply in the six districts in the wards that are wholly or partly within the 60 minute zone, taken from data supplied on a ward-level basis by the South West Tourist Board (2009 survey).

Table A9D.1: Tourist Accommodation in wards within the 60-minute Zone that are in Sedgemoor, Taunton Deane, West Somerset, North Somerset Mendip and South Somerset

	West Somerset	Taunton Deane	Sedgemoor	North Somerset	Mendip	South Somerset	TOTAL
Serviced	1,507	2,203	1,757	2,533	532	125	8,657
Self-Catering	1,228	550	516	434	18	72	2,818
Caravan/ Camping	4,116	734	15,321	1,919	0	174	22,264
Campus/hostel	284	0	67	0	1,097	0	1,448
Total	7,135	3,487	17,661	4,886	1,647	371	35,187

Source: SWTB Database

9D.3.2 There are approximately 35,000 tourist bed spaces within the 60 minute zone. However, this includes 14,600 in holiday villages which HPC workers are unlikely to be able to use. This is an underestimate of the total tourist accommodation in the area because it only includes accredited or "rated" accommodation. There are many businesses that are not rated and therefore do not appear on the SWTB database.

9D.3.3 In assessing the potential availability of tourist accommodation for EDF Energy's workforce, a conservative estimate has been made, based on the peak levels of tourist demand in August. **Table A9D.2** shows the SWTB's estimates of occupancy throughout the year of each type of accommodation likely to be available and used by HPC workers. (Ref. 9D.2).

Table A9D.2: Tourist Accommodation Occupancy Rates in Somerset (2009)

Somerset	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Self-Catering	33%	43%	44%	70%	72%	84%	80%	94%	77%	52%	29%	35%
Camping and Caravan Pitches	5%	4%	15%	19%	63%	64%	59%	81%	45%	22%	21%	27%
Serviced Rooms	35%	47%	54%	60%	67%	67%	74%	76%	73%	64%	55%	50%

Source: SWTB Accommodation Report March 2010

9D.3.4 Average occupancy levels for this accommodation outside of peak holiday periods are typically much lower. **Table A9D.3** shows a comparison of March and August. This shows that there are 24,500 vacant bedspaces in March and 6,500 in August.

Table A9D.3: Comparison Between Tourist Accommodation Vacancy Rates in March and August in Somerset (2009) in the 60-minute Zone

Type	Total	% Vacant in March	No. Vacant in March	% Vacant in August	No. Vacant in August
Serviced	8,748	46%	4,024	24%	2,100
Self-catering	2,873	56%	1,609	6%	172
Caravan/Camping	22,264	85%	18,924	19%	4,230
			24,557		6,502

Source: SWTB Accommodation Report March 2010

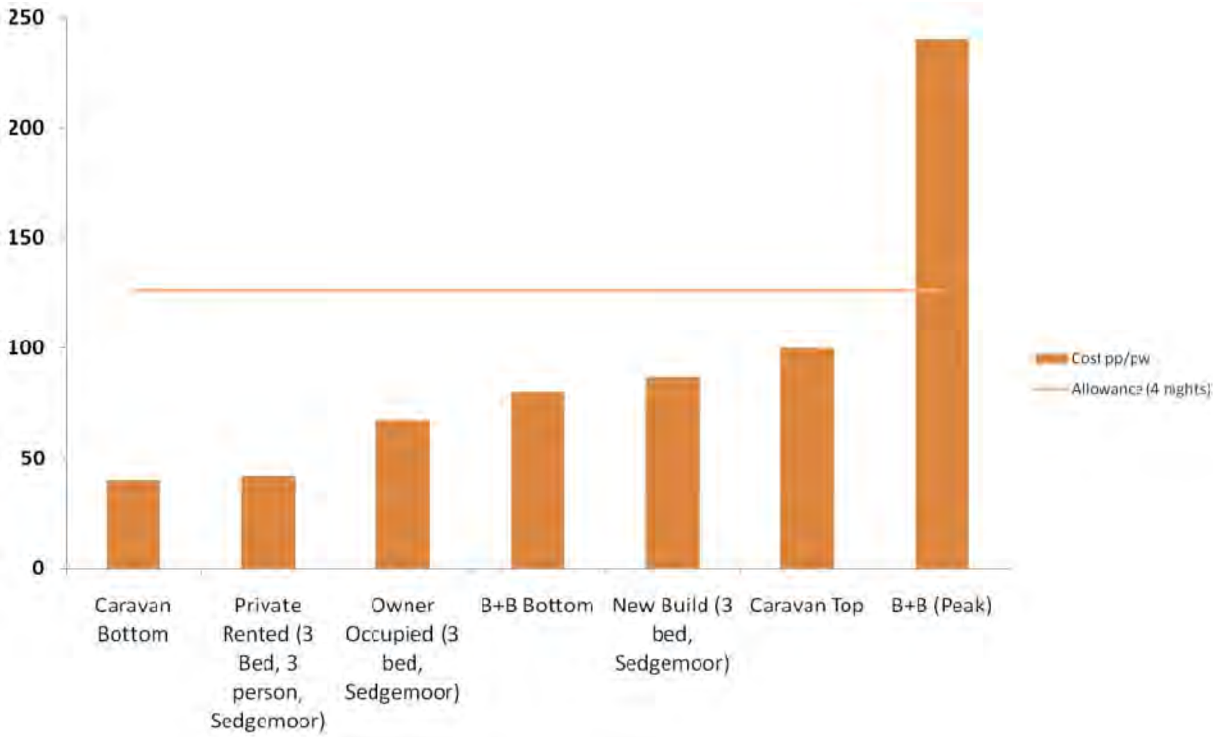
9D.3.5 There is therefore a large pool of tourist accommodation that could potentially be utilised by the construction workforce particularly in off-peak periods. Use of some of this accommodation during off-peak periods would clearly offer economic benefits to tourist accommodation providers and other related local businesses.

9D.3.6 However, it is recognised that not all of this accommodation is suitable for workers. Some rooms will be double or family rooms which workers are unlikely to want to share or be willing to pay a premium for larger accommodation.

9D.3.7 There are also planning restrictions on the use of camping and caravan sites. These include restrictions on the use of sites during winter months, limits on the length of time a person can occupy a site for and restrictions on non-tourist use. This will reduce the available supply to HPC workers below the figure above (and also limit demand to those who want only short-stay accommodation).

9D.3.8 In addition, some accommodation will not be affordable to workers **Plate A9D.1** shows the average costs per week of different forms of accommodation. The horizontal line shows the union-agreed accommodation allowance paid to construction workers (assuming they stay an average of four nights per week, i.e. work five days in every seven). (N.B. Actual pay scales have not been determined, but the chart uses the union-agreed accommodation allowance as a benchmark).

Plate A9D.1: Average Accommodation Costs



Source: Arup; SHMA (Ref. 9D.3); Dataspring (Ref. 9D.4); *EDF Energy*

9D.3.9 This shows that a significant proportion of serviced tourist accommodation will not be affordable to HPC construction workers. However, caravans and the bottom end of the bed and breakfast market will be accessible in price terms.

9D.3.10 To account for the fact that not all accommodation will be suitable or affordable, discounts have been applied to availability.

- Only 40% of serviced accommodation is suitable and affordable.
- Only 25% of camping and caravan sites can be used.

9D.3.11 That leaves an estimate of 2,070 spare bedspaces in August, as shown in **Table** A9D.4.

Table A9D.4: Estimated Supply of Tourist Accommodation

Type	August Vacant & Affordable
Serviced	840
Self-catering	172
Caravan/Camping	1,058
TOTAL	2,070

9D.3.12 In practice, the risk of adverse effects on the tourism sector will also be further reduced by the seasonal pricing operating within tourist markets. Providers tend to put their prices up quite significantly over the peak holiday periods, such that it would not be affordable for the vast majority of Hinkley Point C workers. This is likely to act to significantly reduce the take up by the HPC construction workforce of tourist accommodation during peak periods – for example the average price of a hotel or bed & breakfast accommodation in Somerset in August is substantially above the normal union-agreed accommodation allowance for the majority of the construction workforce. Therefore, the normal operation of market mechanisms would be likely to encourage the use of tourist accommodation mainly during the cheaper non-peak periods when there is significant spare capacity and when the tourism industry stands to benefit from the additional demand generated by the construction workforce.

9D.4 Private Rented Accommodation

9D.4.1 There is a substantial quantity of PRS housing within the 60 minute zone. **Table** A9D.5 shows the number of PRS units at the time of the 2001 Census (Ref. 9D.5) and in 2008 when a Housing Needs Survey was undertaken as part of the local authorities' Strategic Housing Market Assessment. (Ref. 9D.6).

Table A9D.5: Private Rented Accommodation in the wards within the 60-minute zone

District	PRS Units 2001	PRS Units 2008
Sedgemoor	3,199	4,689
Taunton Dean	3,598	5,522
West Somerset	1,347	1,870
South Somerset	335	518
North Somerset	6,457	8,069
Mendip	1,002	1,151
TOTAL	15,958	21,819

9D.4.2 In total it can be seen that there are around 21,800 PRS units in the 60 minute zone. It should be noted that these are PRS units rather than bed spaces. The vast majority of units have more than one bedspace. Data has been collected by SBA that identifies an average of 2.29 bedspaces per PRS unit in Sedgemoor, 2.49 in Taunton Deane, 2.30 in West Somerset, and an average of 2.26 per unit in other local authorities with wards in the 60-minute zone (Based on analysis of 2001 Census). This produces a total of 50,796 bedspaces across the 60 minute travel zone.

9D.4.3 The overall vacancy rate for dwellings in West Somerset, Sedgemoor and Taunton Deane were set out in the Strategic Housing Market Assessment (SHMA) at 3.5%, 4.2% and 3.3% respectively (similar data are not available for the other Districts). However, there is significant difference in vacancy between tenures. The results from the Department for Communities and Local Government's 2008 English Housing Survey (EHS) (Ref. 9D.7) show national average vacancy rates by tenure of housing (where the tenure assigned to vacant properties relates to the previous occupancy), as follows:

- owner-occupied: 2.7% of properties vacant;
- social rented: 4.6% of properties vacant; and
- private rented: 13.3% of properties vacant.

9D.4.4 These vacancy levels exist even when there is significant housing need and when local authorities have housing waiting lists. The existence of need in one part of the market does not demonstrate that there is a shortage of housing overall, or that there is no additional capacity that could be used in some sectors.

9D.4.5 It is also important to note the degree of annual turnover (or 'churn') in the property market. The greater the rate or percentage, the more dynamic the market. There is no comprehensive data on levels of turnover within the local housing stock; however evidence from the Strategic Housing Market Assessment and the Census indicates the following annual turnover (churn) rates in the PRS for which data are included:

- West Somerset:13%;
- Sedgemoor: 20%; and
- Taunton Deane: 24%.

9D.4.6 An indication of the likely degree of turnover can also be obtained from national survey-based evidence. The EHS provides data on the proportion of households living in their current home for less than a year. This provides an indication of typical annual turnover in the housing stock, and illustrates for example the very high churn in the private rented market. The latest results for 2008 are as follows:

- owner-occupied: 4% of households have moved within the last 12 months;
- social rented: 8% of households have moved within the last 12 months; and
- private rented: 36% of households have moved within the last 12 months.

9D.4.7 In order to assess spare capacity in the private rented sector, capacity has been broken down into two components. First, to operate effectively housing markets need a small level of capacity to allow for people in the process of moving, or the process of letting homes. This is called "frictional" capacity. Capacity on top of that can be described as additional or spare capacity and it is this capacity that has been assumed would be available to HPC workers.

9D.4.8 There is no single data source which provides this capacity at the local level so we have used a combination of national and local datasets to identify some parameters.

9D.4.9 Using the English Housing Survey data some parameters can be established. The annual churn rate of 36% equates to an average of 3% of all properties turning over in each month. This would be the absolute minimum vacancy required for the market to function[1]. Using the same dataset, the vacancy rate at a given point in time is 13%, which suggests a maximum spare capacity of up to 10%.

9D.4.10 Using more local data, annual turnover is highest in Taunton Deane at 24%, which means 2% of all stock turns over each month. This sets the minimum benchmark for spare capacity required for the market to function. The local vacancy rate in the PRS is not known, however if it is similar to the national rate this suggests capacity up to a maximum of 11%.

9D.4.11 **Table A9D.6** shows how many bedspaces would be available under different depending upon assumptions made about spare capacity at any given point in time (2.5%-10%). It shows that even with the most cautious assumptions the 900

[1] In practice a slightly higher level would be required to allow some degree of choice.

bedspaces we estimate HPC workers will demand would be available in the PRS and in practice this figure is likely to be significantly higher.

Table A9D.6: Available Bedspaces in Private Rental Sector

District	PRS Bedspaces 2008	2.5% Spare Capacity	5.0% Spare Capacity	7.5% Spare Capacity	10.0% Spare Capacity
Sedgemoor	10,738	268	537	805	1,074
Taunton Dean	13,750	344	687	1,031	1,375
West Somerset	4,301	108	215	323	430
South Somerset	1,170	29	59	88	117
North Somerset	18,235	456	912	1,368	1,824
Mendip	2,602	65	130	195	260
TOTAL Bedspaces	50,796	1,270	2,540	3,810	5,080

Source: English Housing Survey, local data and EDF Energy

9D.5 Owner Occupied

9D.5.1 As set out above, it is estimated that by the time of peak construction, around 450 workers will have moved to the area with their families. Some of these will form part of the operational workforce, others will be long-term construction workers.

9D.5.2 If spread over a number of years, this should be within the capacity of the local housing market, and may provide a valuable boost if the housing market remains subdued.

9D.5.3 If spread over four years of the construction programme, the resulting 100+ units per year would account for no more than 3% of all sales registered with the Land Registry in 2009, which was a low year for sales. A comparison with the higher level of sales in 2006 reduces the figure to only 1.5%. (Ref. 9D.8) These are very small impacts in the context of the regular churn of the owner–occupied housing market.

9D.6 Latent Accommodation

9D.6.1 In late 2009 and again in the spring of 2011 an advertisement was placed in several local weekly papers (Bridgwater Mercury, West Somerset Free Press, Somerset County Gazette and Burnham and Highbridge Times) inviting people to register an interest in providing accommodation to HPC workers. In addition to private rented properties, this provided a source of 'latent' accommodation, i.e. property which had not previously been offered for rent and primarily comprising rooms within people's houses. As a consequence of these advertisements and ongoing calls to EDF Energy, over 1,500 bedspaces in private accommodation have been registered to date of which over 400 are rooms within people's houses.

9D.6.2 It is likely that the amount of latent accommodation of this kind will increase over time as the construction phase starts and more people realise that they can take advantage of the commercial opportunities which arise from it. Once people are aware of construction workers arriving in the area, and see others they know renting out rooms, it is likely that more people will come forward with offers of rooms to rent. EDF Energy has recently contacted those who expressed an interest in providing accommodation to check their availability and from a limited sample it appears that most of the rooms remain available to rent.

9D.7 Summary of Accommodation Capacity

9D.7.1 Based on the above analysis it is estimated that, during the peak tourist period, and looking across all sources of accommodation, the minimum capacity that HPC construction workers would be able to use across the 60 minute zone without creating any risk of significant disruption to accommodation markets is 4,200 spaces. As explained above, this figure is based on very conservative assessments of spare capacity, in particular in relation to tourist accommodation where there is much more spare capacity outside the peak tourist season. For most of the year, there will be much more accommodation available without any risk of significant disruption to accommodation markets.

9D.7.2 This central estimate of total spare capacity is based on a number of assumptions, most notably about the spatial spread of workers and about the split between different types of accommodation that workers are likely to use. Whilst EDF Energy has some influence over the choices workers make, and can encourage them to make choices that fit better with available supply, it will not be able to direct them to specific locations or types of accommodation and workers are free to make their own decisions. The Accommodation Strategy needs to allow for that, and therefore does not assume that workers can, or should, use all the existing spare capacity across the 60 minute zone.

APPENDIX 9E: SOCIO-ECONOMIC TECHNICAL NOTE 5: SPORT / LEISURE AUDIT AND ESTIMATED DEMAND

FOREWORD

EDF Energy and the local authorities wish to ensure that they understand what sports and leisure facilities the temporary Hinkley Point C (HPC) construction workers will require, and the extent to which these are already provided in the areas where workers are expected to live.

This report includes an audit of existing provision of sports facilities in Sedgemoor, West Somerset and Taunton Deane districts, and calculates the estimated usage of facilities by number and typology of construction workers.

9E. SOCIO-ECONOMIC TECHNICAL PAPER 5: SPORT / LEISURE AUDIT AND ESTIMATED DEMAND

9E.1 Introduction and Methodology

9E.1.1 EDF Energy and the local authorities wish to ensure that they understand what sports and leisure facilities the temporary Hinkley Point C (HPC) construction workers will require, and the extent to which these are already provided in the areas where workers are expected to live.

9E.1.2 This report includes an audit of existing provision of sports facilities in Sedgemoor, West Somerset and Taunton Deane districts, and calculates the estimated usage of facilities by number and typology of construction workers.

9E.1.3 The approach taken to assessment of the existing provision of sports facilities is based on two sources of information:

- A survey undertaken by ARUP in 2010 which highlights the location and type of a range of sports and leisure facilities in West Somerset and Sedgemoor.
- Sport England's Active Places database, (Ref. 9E.1) which includes a list of facilities by type and size/capacity for all areas, and Sports Facilities Calculator. (Ref. 9E.2).

9E.1.4 Expected demand is based on an estimate of the workforce age and gender profile which is then entered into Sport England's Sports Facilities Calculator.

9E.2 Workforce Profile and Typologies

9E.2.1 The demand for sports and leisure facilities arises particularly from the proposed temporary increase in population as a result of the construction stage of Hinkley Point C.

9E.2.2 EDF has been working with the Councils to agree the evidence base for assessing the likely impacts of the HPC scheme. This has involved the production of a series of "Technical Notes". **Technical Note 1** (which has been signed off by the Councils) sets out the overall workforce profile and **Technical Note 2** (which is being reviewed by the Councils) sets out the demographic breakdown of the workforce.

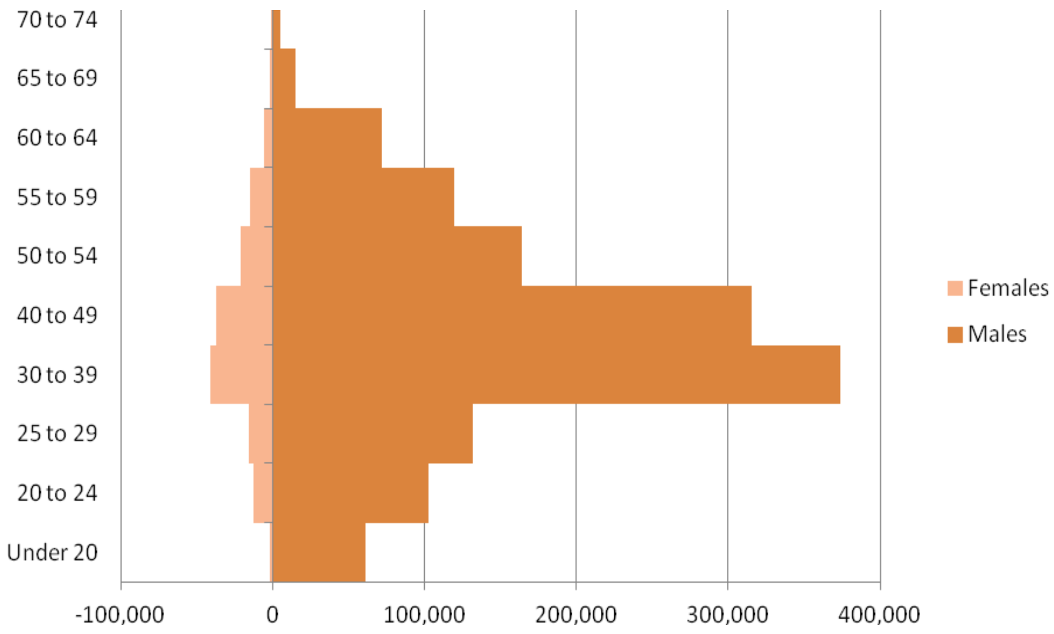
9E.2.3 The overall HPC construction workforce is expected to peak at 5,600, of which 3,700 (66%) will be non-home-based, i.e. will temporarily move into the area and therefore cause a temporary increase in demand for sports and leisure facilities.

a) Age and Gender

9E.2.4 Analysis has been undertaken using publicly-available datasets from the 2001 Census to outline the age and gender profile of construction workers in England and

South West England in particular. (Ref. 9E.3) The following split has been applied to the total non-home-based construction workers estimated at Hinkley Point C.

Plate 1.1: Age and Gender Profile Non-Home-Based HPC Workers



9E.2.5 The largest age group in the construction industry are males in their 30s, who make up 25% of the of all construction workers. The next largest group is males in their 40s, at 21%, followed by those over 50 and under 30 who make up around 19% of the industry each. Females make up 10% of the industry and they are fairly evenly distributed amongst the age groups.

b) Education

9E.2.6 According to 2001 Census data 70% of construction workers are educated to GCSE level or below; 15% are educated to A level or above. The following table translates Census (2001) data into a breakdown of expected age group and qualification level for non-home-based employees at Hinkley Point C.

Table A9E.1: Qualification Level of Non-Home-Based Workers

Age Group	Qualification Level	
	Level 3 or Lower	Level 4 or Higher
Males Under 35	1,081	101
Males 35-49	1,125	105
Males 50+	838	78
Females Under 35	117	15
Females 35-49	127	16
Females 50+	98	13

Source: Census 2001

c) Leisure Preferences

9E.2.7 Sport England, in partnership with Experian, has developed a market segmentation model to analyse the sport and leisure behaviour of England's residents based on age, gender, life situation and socio-economic characteristics. (Ref. 9E.4) Each segment is assigned a named representative person, who embodies the key characteristics of the group.

9E.2.8 Using this data, and the demographics above, we can make some predictions as to what the leisure needs of construction workers at Hinkley Point C may be.

i. Jamie

9E.2.9 Male operative construction workers in their teens and twenties will make up approximately 29% of the workforce. Sport England identifies this group as 'Jamies'. Jamie is:

- under the age of 35;
- is educated to below degree level, most likely in a vocational qualification; and
- is likely to be working class

9E.2.10 60% of this group do 30 minutes of sport at least once a week (compared to a national average of 40%) and 31% do so at least 3 times a week (compared to an average of only 15%).

9E.2.11 The most popular sports for this group are football (28%) and keep fit/gym (22%). Around 30% are members of teams or clubs, and 24% take part in competitions. This reflects the fact that amongst the most commonly cited reasons for doing sport amongst this group are: 'to meet with friends' and 'just to enjoy it.' Improving personal performance and keeping fit are also important, but losing weight is not a consideration.

9E.2.12 The group is hampered in their access to sport because they left school, have no opportunity to take part, or because of economic and work reasons. Work commitments are a concern for 27% of this group, compared to only 19% in the general population.

9E.2.13 The group is least satisfied by the quality of coaching, officials and available facilities, and have a lower impression of the value for money of sport than other groups. Improved facilities are by far the most commonly cited improvement that would encourage this group to do more sport.

9E.2.14 Apart from sport, the most common out of home pastimes for this group is going to pubs, bars and clubs or go to the cinema. They are more unlikely than most groups to visit libraries, museums or the theatre.

ii. Kev

9E.2.15 Male operative construction workers in their 30s and 40s are expected to make up approximately 30% of the workforce. Sport England identifies this group as 'Kevs'. Kev is:

- between the ages of 25 and 56, but is most likely to be 36-45;

- is likely to work in a vocational job; and
- is likely to be working class.

9E.2.16 42% of this group take part in sport at least once a week, and 17% do so at least three times a week. The most popular sports in this group are going to the gym or keep fit (14%); football (11%) and cycling (11%). They also swim and take part in athletics. 33% take part in organised sport, but only 16% take part in competitions.

9E.2.17 The group mostly take part in sport 'just to enjoy it' but also consider keeping fit to be important. Work commitments are the most likely factor to prevent the group from doing as much sport as they would like to. 'Being less busy' is the most commonly cited factor that would increase uptake.

9E.2.18 The group's satisfaction levels are broadly in line with the general population. They are especially dissatisfied by the quality of facilities and coaching. They are less satisfied with their levels of fitness than average.

9E.2.19 The group are not that likely to take part in much leisure outside the home. 57% go shopping and 54% go to restaurants, but these proportions are both less than in the general population. They are less likely than other groups to visit the theatre, library or museums.

iii. Terry

9E.2.20 Male operative construction workers in their 50s and older will be expected to make up approximately 22% of the workforce. this group are represented by Terry who:

- is aged 46-65;
- is likely to be working class, or living at subsistence level;
- works or did work as a manual labourer; and
- suffers relatively high levels of deprivation (according to the IMD) than other groups, especially with health and disability.

9E.2.21 25% of this group play sport at least once a week, but only 8% do so three times a week or more. 70% did no sport at all in the four weeks prior to the survey. The group are most likely to go to the gym (8%), or go cycling or swimming (6% each) but these levels are significantly lower than in the wider population.

9E.2.22 17% of the group are members of a club, but only 4% play team sports. Like their younger counterparts, the group's main motivation for taking part in sport is enjoyment, followed by the desire to keep fit. The group is most hampered by their injuries and disabilities, with 59% citing this as a reason for not doing as much sport as they would like. 17% of the group would do more sport if they had someone to go with.

9E.2.23 The group are less likely than average to take part in leisure activities in general. Outside the home, 56% go shopping, 55% go on days out and 41% go to bars or pubs. The group is one of the least likely to visit libraries, museums or the theatre.

iv. Paula

9E.2.24 Female operative construction workers (approximately 9% of the workforce) are likely to be in the 'Paula' market segment. Paula is:

- aged 18-45, but most commonly between 25 and 36;
- is likely to be a single mother; and
- is likely to be in low skilled or part time work .

9E.2.25 36% of this group take part in sport at least once a week and 12% do so at least three times a week. However, 63 % did not sport at all in the four weeks prior to the survey. They are unlikely to be members of a club or to compete. The most popular activities in this group are going to the gym (18%) swimming (17%).

9E.2.26 This group take part in sport because they enjoy it, (21%) to keep fit (26%) and to take their children (21%). The most important reason for not doing as much sport as they would like is family commitments, which affects this group far more than the average. Factors such as leaving school, lack of opportunities and economic and work reasons are also important.

9E.2.27 The group is slightly more satisfied with overall sports provision than the average. However, they have below average satisfaction with the 'social aspects' of the sports experience, such as feeling comfortable in the sports environment, taking part without feeling embarrassed or awkward and having their cultural and religious beliefs respected. They are also slightly less satisfied than average with the 'ease of participation' which takes into account of issues such as transport access and balancing leisure time with work and family commitments.

9E.2.28 36% of this group would do more sport if they were less busy and 33% would do so if admission prices were cheaper. Admission prices are more important for this group than for any other of the market segments.

9E.2.29 This group goes shopping for leisure more often than average, with 85% going shopping in their spare time, 59% go on days out and 57% go to restaurants. In the last 12 months, this group were least likely to have been to the theatre or to a museum but were much more likely than their male counterparts to have been to a library.

v. Ben, Tim and Phillip

9E.2.30 Male workers above operative level are likely to make up approximately 8% of the workforce. Those working above operative level, in administrative or in managerial positions who are educated to degree level or above are likely to be in the Ben (18-25); Tim (25-45) and Phillip (46+) market segments, according to their age.

9E.2.31 These segments play more sport than any others in their respective age groups, with 68% of Bens, doing sport at least once a week, 62% of Tims, and 51% of Phillips.

9E.2.32 Football and going to the gym are significant sports for all age groups, but cycling and swimming are increasingly important in the older groups. All groups would like to increase their uptake of swimming and cycling. Participation in football declines from 33% in the 18-24 group to 9% in the 46+ group. However, it is suggested that the older men are likely to continue to be connected to football in club administration capacities, such as club secretary, and 30% retain club membership, so football remains important socially.

9E.2.33 Work commitments are the main reason that these segments do not do as much sport as they like, with more than 30% in each age group with this concern. All groups are least satisfied with the quality of facilities and coaching on offer.

9E.2.34 The younger groups are most likely to see go out to pubs, bars or clubs or to the cinema. As they get older, pubs and bars are replaced by restaurants and days out become more important. ‘Tim’ is the most likely to go to museums and galleries (62%) or to the theatre (57%). Participation amongst Bens and Philips is slightly lower. These groups are less likely than others in their age groups to visit libraries.

vi. Chloe and Jackie

9E.2.35 Female workers above operative level are likely to make up approximately 0.5% of the workforce. This small group is likely to be represented by Chloe (mainly early 20s) and Jackie (late 20’s+). Chloe is more likely than other women in her age group to do sport at least once a week, with 62% doing so. However, participation for Jackies is lower, at 49%, mostly due to the pressures of having a family. These groups are most likely to swim or go to the gym, and they like to do more of both. Jackies would benefit much more than average from help with childcare.

9E.2.36 Younger women are slightly more likely than average to go to museums, galleries, libraries or the theatre, whilst the older group are slightly less likely than average to do so. Shopping is an important pastime for both groups, whilst eating in restaurants and going to pubs are more popular pastimes for younger women.

vii.Families

9E.2.37 Around 500 non-home-based workers live in family-type households, i.e. with one or more dependents (although not necessarily children). In order to assess the demand for sports facilities created by this element, it has been estimated that each family contains one construction worker, 1.2 non-construction-worker adults and 0.85 children. This is an estimate for peak employment, which is scaled down ‘pro-rata’ for non-peak times (subtracting the weighting of the campuses, which are not expected to house families).

viii. Summary

9E.2.38 For the demographic of non-home-based workers, football and going to the gym are by far the most important sports. The vast majority of workers will be “Jamies” and “Kevs” for whom football and the gym are the main activities, along with cycling which is undertaken by 11% of Kevs. There is very limited demand for swimming and racquet sports barely feature in the demand profiles.

9E.3 Estimate of Sport / Leisure Facilities Demand

9E.3.1 Sport England provides a Sports Facility Calculator (SFC) to enable developers to assess the demand for sports facilities likely to arise from the permanent residents of their development. This calculator assesses the demand likely to arise for swimming pools, sports halls, indoor bowls and synthetic pitches.

9E.3.2 The Sports Facility Calculator (SFC) was created by Sport England to help local planning authorities quantify how much additional demand for the key community sports facilities (swimming pools and sports halls) is generated by populations of new growth, development and regeneration areas. The SFC was first developed to help estimate the facility needs of the new communities in the Eastern Quarry Development, Dartford, and the Milton Keynes future growth areas. It has been used to help local authorities in infrastructure planning, s.106 and Supplementary Planning Documents. The key functions of the SFC are:

- expresses demand as facilities, e.g., 400m^2 of water;
- uses local authority population profiles from the 2001 census;
- allows you to create your own population profile;
- has the ability to test out the effect of changes in levels of participation;
- converts need for facilities into price/value (£); and
- includes up to date regional building cost variations

9E.3.3 Whilst the SFC can be used to estimate the swimming and sports hall needs for whole area populations, such as for a whole local authorities, there are dangers in how these figures are subsequently used at this level in matching it with current supply for strategic gap analysis.

9E.3.4 The SFC should not be used for strategic gap analysis; this approach is fundamentally flawed. The SFC has no spatial dimension. The figure that is produced is a total demand figure for the chosen population. It is important to note that the SFC does not take account of:

- facility location compared to demand;
- capacity and availability of facilities - opening hours;
- cross boundary movement of demand;
- travel networks and topography; and
- attractiveness of facilities

9E.3.5 The model then applies the costs of provision associated with the county that the population is expected to live within.

9E.3.6 The SFC uses information Sport England has gathered on who uses facilities and then applies this to the actual local population profile of the local area. The SFC then turns this estimation of demand (visits per week) into the equivalent amount of facility which is needed to meet these visits each week.

9E.3.7 The SFC works by applying nationally derived demand rates to the existing local population profile of the local area. However, in this instance, the temporary non-home-based population that is expected to arise from the proposed development will have a different population profile than the existing area. Therefore, a population profile has been manually inserted into the SFC based on the demographic data outlined in Section 2.

9E.3.8 Estimates for demand have been undertaken in terms of the total demands of the temporary non-home-based construction workforce and associated families, and by smaller areas based on the estimated distribution of non-home-based construction workers as expressed in SBA's June 2011 'gravity model'. These ward clusters are outlined in **Figure 1.1**, including the estimated number of non-home-based construction workers at peak.

9E.3.9 An important consideration is that the SFC is based on **permanent** residents whereas demand of non-home-based workers at Hinkley Point C is temporary. The Sports Facilities Calculator is based on demand arising from permanent housing. In the case of HPC the increase in residents will be temporary over a nine year period, peaking at 3,700 in month 64 of construction. Simply feeding in the increase in population at peak (or at any point) would therefore overstate the demand for facilities. We need to convert the number of workers moving into the area into an equivalent permanent population.

9E.3.10 It is estimated that the construction of HPC will require 20,000 to 25,000 person years of construction work (50 million hours). Of these, 63% will be non-home based. Over the nine year construction period the top end of this range equates to an annual average of close to1,800 people being temporarily in the area to construct HPC.

9E.3.11 Whilst nine years is a relatively long time, it is less than the expected lifespan of most sports facilities. For example, the life of a swimming pool is 30 years (UK Sports Council (1999) Technical Unit for Sport, Handbook of Sports & Recreational Building Design) with refurbishment required after 10-15 years (Sport England (2008) Design Guidance, Swimming Pools). A further adjustment therefore needs to be made to account for that. Allowing for use in nine years of the 15 year maintenance lifespan of the facility means a further reduction of just over a quarter, or the equivalent of 1,310 permanent residents – an overall adjustment of 65% to convert from temporary residents to a permanent equivalent. The same lifespan / maintenance period is applied to sports halls.

9E.3.12 The following assessment is based on Sport England's Sports Facilities Calculator, applied to a 'user profile' based on the likely demographic characteristics of non-home-based workers and families and children at two intervals during the construction period. The first assessment point is immediately prior to completion of the campuses, and the second is at overall construction peak when non-home-based workforce is at its highest. Assumptions on the gender and age split of the construction workforce have been based on 2001 Census data, and each 'family' is estimated to contain 0.85 children, as outlined in the Methodology section.

9E.3.13 The following table outlines the number of non-home-based workers at 27 months (the month before the Campuses are 'on-line') and 64 months (peak construction employment), identifying within that the number of families (partners) and the Sport England Facilities Calculator outputs for each interval.

Table A9E.2: Sports Facilities Demand Arising from Non-Home-Based Workers at 27 Months and 64 Months (Peak) (Sport England, 2010)

		27 Months	64 Months (Peak)	Permanent Equivalent (Peak)
Total Construction Workers		3,026	5,600	
% of which non-home-based		54%	66%	
# non-home-based		1,798	3,746	
Families (pro-rata)		286	500	
Children		243	425	
Sports Facilities Calculator				
Pools	**Area**	17.24	35.92	23.35
	Lanes	0.32	0.68	0.44
	Pools	0.08	0.17	0.11
Halls	**Courts**	0.62	1.29	0.84
	Halls	0.15	0.32	0.21

	Centres	0.01	0.03	
Synthetic Pitches	**Pitches**	0.09	0.19	

Source: Sport England 2010, Quod

9E.3.14 The Sport England Sports Facilities Calculator does not include the estimated demand for provision of gyms / health and fitness suites. Separate Sport England guidance suggests that the provision of 38 gym stations per 10,000 population is adequate provision.

9E.4 Existing Provision and Estimated Demand by Ward Cluster

9E.4.1 The Annex to this document outlines the existing provision in the area. In addition to this, there will be new on-site sports facilities provided at the BRI-A campus in Bridgwater and at the HPC site campus. This will include two synthetic pitches and a gym at each.

9E.4.2 This shows that in aggregate, the additional demand from HPC workers is modest. However, there may be local under-provision in some areas where HPC workers will live. The need for facilities locally has therefore been assessed and compared to estimated demand arising from non-home-based workers in 12 clusters across the three districts.

9E.4.3 Unfortunately, the audit undertaken by Arup does not include analysis of usage or capacity, only whether facilities exist or not. This assessment is therefore necessarily limited to whether or not facilities exist to meet forecast demand from temporary HPC workers.

9E.4.4 The following table summarises areas where facilities do not exist to meet forecast demand (using the “permanent equivalent” definition set out above):

Table A9E.3: Unmet Existing Demand for Sports Facilities (Permanent Equivalent)

Area	Possible Unmet Demand
Minehead	<0.01 of a swimming pool
Watchet/Williton	<0.01 of a swimming pool
Hinkley	0.01 of a swimming pool
Weston-Super-Mare	Adequate provision
Burnham/Highbridge	Adequate provision
Bridgwater	0.02 of a swimming pool
Cannington	<0.01 of a swimming pool <0.01 of a sports hall
Taunton	Adequate provision
Glastonbury	Adequate provision
Cheddar	Adequate provision
Somerset South	Adequate provision
Somerset West	<0.01 of a swimming pool

9E.5 Summary

9E.5.1 The Hinkley Point C (HPC) non-home-based workforce peaks at 3,700 and averages around 1,800 across the nine years of the construction phase.

9E.5.2 The age and gender profile of the workforce has been estimated based on the 2001 Census data for the construction industry.

9E.5.3 Estimates of demand for sports facilities have been based on the Sport England Sports Facilities Calculator (SFC). This relates to the need for new facilities for new permanent residential communities. The non-home-based workforce is only temporary and therefore an adjustment has been made to take account of this. The following table shows the additional demand at the peak and the average across the whole construction period.

Table A9E.4: Additional Demand for Sports Facilities: Peak and Average for Construction Period

Sports Facilities Calculator				
		Average	**Peak**	**Permanent Equivalent (Average)**
Pools	**Area**	17.24	35.92	11.21
	Lanes	0.32	0.68	0.21
	Pools	0.08	0.17	0.05
Halls	**Courts**	0.62	1.29	0.40
	Halls	0.15	0.32	0.10
Indoor Bowls	**Rinks**	0.09	0.18	

Sports Facilities Calculator				
		Average	**Peak**	**Permanent Equivalent (Average)**
	Centres	0.01	0.03	
Synthetic Pitches	**Pitches**	0.09	0.19	

9E.5.4 The Sport England Sports Facilities Calculator does not include the estimated demand for provision of gyms / health and fitness suites. Separate Sport England guidance suggests that the provision of 38 gym stations per 10,000 population is adequate provision.

9E.5.5 In addition to the SFC, Sport England has produced typologies of demand for a wider range of sports, based on key demographics such as age, gender and employment. For the demographic of non-home-based workers, football and going to the gym are by far the most important sports, along with cycling which is undertaken by a much smaller proportion. There is very limited demand for swimming, and racquet sports barely feature in the demand profiles.

9E.5.6 Demand for sports facilities is therefore very modest and is likely to be able to be met from existing provision. The exception to this is swimming pools in Minehead and Bridgwater where there is no publicly available swimming pool at present (although this may change in the near future).

9E.5.7 The provision being made on the campuses will meet most sports needs, and if this is made publicly available (either during construction or as legacy) this could be used as an off-set for the small provision of swimming pools that could be needed as mitigation.

9E.5.8 The Sports Facilities Calculator also gives indicative costs for the provision of sports facilities. In the case of the facilities (or proportions of facilities) outlined in **Table** A9E.2, this would equate to £425,794 for permanent equivalent provision at Month 27.

9E.5.9 The estimated cost of the facilities outlined above, in addition to the cost associated with the replacement of existing facilities at the Bridgwater Sports and Social Club (Bridgwater A site) is lower than the commitment to significant investment in local leisure provision in West Somerset and Sedgemoor districts as set out in the S106 for Site Preparation, and summarised in the **Section 106 Heads of Terms which are appended to the Planning Statement**.

ANNEX: ASSESSMENT OF LOCAL DEMAND FOR FACILITIES

9E.6 Minehead Ward Cluster

9E.6.1 The Minehead ward cluster, to the west of HPC, covers the northern area of Exmoor National Park and incorporates the coastal settlements of Minehead and Porlock.

a) Existing Facilities

9E.6.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.1**):

Table A9E.5: Sports Facilities in the Minehead Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
MI1	Carhampton Recreation Ground	Both	1 Cricket Pitch And 1 Badminton Court
MI2	Dunster Playing Field	Outdoor	2 Pitches (1 Full Size Football And 1 Cricket Pitch)
MI3	Minehead Barbarians RFC	Outdoor	1 Senior Rugby Union
MI4	Minehead Barbarians RFC	Outdoor	2 Senior Rugby Union Pitches
MI5	West Somerset Sports And Leisure Centre	Both	6 Lane Athletics Track, 4 Badminton Courts
MI6	West Somerset Community College	Outdoor	4 Pitches (2 Cricket Pitches, 1 Full Size Football, 1 Senior Rugby Union)
MI7	King George Fifth Recreation Grounds	Outdoor	1 Full Size Football Pitch
MI8	Minehead Middle School	Both	3 Pitches (1 Cricket Pitch, 1 Junior Football, 1 Rounders)
MI9	Minehead Bowling Club	Indoor	1 Rink
MI10	Minehead Football Club	Outdoor	1 Full Size Football Pitch
MI11	Butlins Skyline	Indoor	Leisure Pool (5 Lanes)
MI12	Minehead And West Somerset Golf Club	Outdoor	18 Hole Golf Course
MI13	Northfield Hotel Leisure Club	Indoor	Learner/Training/Teaching
MI14	Wheddon Cross Playing Fields	Outdoor	2 Pitches (1 Junior Football, 1 Cricket Pitch)
MI15	Allerford Recreation Ground	Outdoor	3 Pitches (2 Junior Football, 1 Cricket Pitch)
MI16	Porlock Recreation Ground	Outdoor	3 Pitches (1 Full Size Football, 1 Junior Football, 1 Cricket)
MI17	Hoburne Blue Anchor Caravan Park	Outdoor	Leisure Pool

9E.6.3 The following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.2**).

Table A9E.6: Sports Facilities in the Minehead Ward Cluster (ARUP Audit, 2010):

Code	Name	Facilities
Mia	Minehead Lawn Tennis Club	Tennis Courts x4
MIb	Hoburne Blue Anchor Holiday Park	Golf, Swimming
MIc	Blue Anchor Beach	Swimming
Mid	Dunster Packhorse Playing Field	Cricket, Football
Mie	Dunster Memorial Hall	Gymnastics
MIf	Minehead First School	Football (Youth), Gymnastics, Martial Arts, Netball, Swimming
MIg	Carhampton Village Hall	Badminton, Gymnastics, Martial Arts
MIh	Carhampton Recreation Field	Basketball, Cricket, Football (5-a-side)
MIi	King George V Playing Field	Football
MIj	Irnham Road Playing Field	Basketball, Football x2, Tennis Courts x2
MIk	Minehead Bowling Green	Bowls
MIl	Blenheim Gardens	Golf
MIm	Minehead Barbarians RFC	Rugby Pitches x2
Min	Timberscombe Playing Area	Football (Youth)
Mio	Alcombe Village Hall	Gymnastics
MIp	Withycombe War Memorial Hall	Bowls, Gymnastics
MIq	Timberscombe Cricket Club	Cricket x2
Mir	Butlins Minehead	Basketball x3, Football (5-a-side) x2, Football x2, Golf, Gymnastics, Swimming, Tennis x3
MIs	Minehead and West Somerset Golf Club	Golf
MIt	West Somerset Table Tennis Club	Table Tennis
MIu	The Dance Centre	Gymnastics
MIv	West Somerset Leisure Centre	Athletics, Badminton x4, Basketball x5, Cricket x4, Football (5-a-side) x2, Football, Gym x2, Gymnastics x2, Netball x3, Rugby, Squash x, Tennis x4
MIw	Minehead Middle School	Athletics, Cricket, Gym, Gymnastics, Netball x2, Swimming, Tennis x2
Mix	Timberscombe Village Hall	Gymnastics, Martial Arts
MIy	Plover Close MUGA	Basketball, Football (5-a-side)

b) Demand for Facilities

9E.6.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 57 non-home-based construction workers on average and 119 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.7: Sport England Sports Facilities Calculator Output: Minehead

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.55	1.14	0.74
	Lanes	0.01	0.02	0.01
	Pools	0.00	0.01	0.00
Halls	**Courts**	0.02	0.04	0.03
	Halls	0.00	0.01	0.01
Indoor Bowls	**Rinks**	0.00	0.01	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.01	

9E.6.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.01 sports halls, and 0.01 synthetic turf pitches. At present in the Minehead ward cluster, there are no indoor swimming facilities. However, there is currently good provision of sports halls, pitches and bowling facilities along with notable multiple provision of facilities at West Somerset Leisure Centre.

9E.7 Weston-Super-Mare Ward Cluster

9E.7.1 The Weston-Super-Mare ward cluster, to the north-east of HPC, covers the coastal area north and south of Weston-Super-Mare, including the smaller settlements of Bourton-St-Georges and Locking.

a) Existing Facilities

9E.7.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.3**):

Table A9E.8: Sports Facilities in the Weston-Super-Mare Ward Cluster (Sport England Active Places, 2011):

Code	Name	Type	Facilities
WSM1	BLAGDON CRICKET CLUB	Outdoor	1 Cricket Pitch
WSM2	WINSCOMBE SPORTS CLUB	Outdoor	1 Cricket Pitch, 1 Football Pitch, 1 Junior Football Pitch, 2 Rugby Pitches
WSM3	JUBILEE SPORTS FIELD	Outdoor	1 Junior Football Pitch
WSM4	SPRINGWOOD SPORTS FIELD	Outdoor	1 Football Pitch
WSM5	OLD BANWELL PLAYING FIELDS	Outdoor	1 Cricket Pitch, 2 Football Pitches

Code	Name	Type	Facilities
WSM6	THE CAMPUS	Both	1 Football Pitch, 2 Junior Football Pitches, 2 Badminton Court
WSM7	PRIORY COMMUNITY SCHOOL	Both	2 Cricket Pitches, 5 Football Pitches, 4 Rugby Pitches, 4 Badminton Courts, 1 Floodlit Synthetic Pitch
WSM8	CASTLE BATCH PRIMARY SCHOOL	Outdoor	1 Junior Football Pitch, 1 Rounders Pitch
WSM9	QUEENSWAY PLAYING FIELDS	Outdoor	2 Junior Football Pitches
WSM10	WORLE RECREATION GROUND	Outdoor	1 Football Pitch, 1 Junior Football Pitch
WSM11	WORLE COMMUNITY SCHOOL	Both	1 Cricket Pitch, 2 Football Pitches, 2 Junior Football Pitches, 4 Rounders Pitches, 2 Senior Rugby Pitches
WSM12	MEAD VALE PRIMARY SCHOOL	Indoor	1 Badminton Court
WSM13	BAYTREE RECREATION GROUND	Outdoor	1 Cricket Pitch, 2 Junior Football Pitches
WSM14	WORLEBURY GOLF CLUB	Outdoor	1 Standard Golf Course
WSM15	KEWSTOKE VILLAGE HALL	Both	1 Football Pitch, 1 Junior Football Pitch, 1 Badminton Court
WSM16	SAND BAY LEISURE RESORT	Both	18 Stations, 20m Swimming Pool
WSM17	HORNETS RFC	Outdoor	2 Rugby Pitches
WSM18	HUTTON MOOR LEISURE CENTRE	Both	1 Cricket Pitch, 4 Football Pitches, 2 Junior Football Pitches, 2 Rugby Pitches, 110 Stations, 8 Badminton Courts, 8 Lane 25m Swimming Pool
WSM19	ESPORTA HEALTH & FITNESS (WESTON)	Indoor	120 Stations, 4 Lane 25m Swimming Pool
WSM20	ASHCOMBE PRIMARY SCHOOL	Outdoor	2 Junior Football Pitches
WSM21	BODYTONE HEALTH AND FITNESS	Indoor	59 Stations
WSM22	SWEAT FITNESS ACADEMY	Indoor	50 Stations
WSM23	GYM CENTRAL	Indoor	75 Stations
WSM24	VICTORIA BOWLING CLUB	Indoor	1 Indoor Bowls Rink
WSM25	WOODSPRING INDOOR BOWLS CLUB	Indoor	2 Indoor Bowls Rinks
WSM26	YMCA (WESTON-SUPER-MARE)	Indoor	1 Badminton Court
WSM27	WESTON COLLEGE	Indoor	1 Badminton Court
WSM28	TRIM WISE HEALTH + FITNESS	Indoor	40 Stations
WSM29	DROVE ROAD RECREATION GROUND	Outdoor	1 Cricket Pitch, 2 Football Pitches, 4 Hockey Pitches, 4 Rugby Pitches
WSM30	WESTON-SUPER-MARE RFC	Outdoor	1 Rugby Pitch
WSM31	WYVERN SPORTS CENTRE	Both	1 Football Pitch, 1 Rugby Pitch, 15 Stations, 4 Badminton Courts, 1 Floodlit Synthetic Pitch

Code	Name	Type	Facilities
WSM32	CLARENCE PARK	Outdoor	1 Cricket Pitch, 1 Football Pitch
WSM33	WESTON-SUPER-MARE GOLF CLUB	Outdoor	1 Standard Golf Course
WSM34	BROADOAK MATHEMATICS AND COMPUTING COLLEGE	Both	1 Football Pitch, 1 Junior Football Pitch, 2 Rugby Pitches, 4 Badminton Courts
WSM35	WESTON-SUPER-MARE CRICKET CLUB	Both	2 Cricket Pitches, 2 Badminton Courts
WSM36	UPHILL CASTLE CRICKET CLUB	Outdoor	1 Cricket Pitch
WSM37	ST. ANDREWS INDOOR BOWLS CLUB	Indoor	3 Indoor Bowls Rinks
WSM38	WESTON-SUPER-MARE AFC	Both	4 Football Pitches, 1 Badminton Court
WSM39	WESTON ST JOHNS FOOTBALL CLUB	Outdoor	1 Football Pitch
WSM40	OLDMIXON RECREATION GROUND	Outdoor	2 Junior Football Pitches
WSM41	SIDCOT SCHOOL SPORTS FIELD	Outdoor	1 Cricket Pitch, 2 Football Pitches, 1 Hockey Pitch, 3 Rounders Pitches, 3 Rugby Pitches
WSM42	SIDCOT SCHOOL	Indoor	4 Badminton Courts
WSM43	BANWELL PRIMARY SCHOOL	Indoor	1 Badminton Court
WSM44	BANWELL FOOTBALL CLUB	Outdoor	1 Football Pitch
WSM45	AVON SKI CENTRE	Outdoor	4 Ski Slopes
WSM46	WESTON-SUPER-RANGE	Outdoor	1 Driving Range, 1 Par3 Course
WSM47	CHURCHILL SPORTS CENTRE	Both	1 Cricket Pitch, 1 Football Pitch, 2 Junior Football Pitches, 22 Stations, 4 Badminton Courts, 5 Lane 20m Swimming Pool
WSM48	BANWELL & CHURCHILL CRICKET CLUB	Outdoor	1 Cricket Pitch
WSM49	CHURCHILL PARISH RECREATION GROUND	Outdoor	2 Football Pitches
WSM50	CHURCHILL C OF E PRIMARY SCHOOL	Outdoor	1 Junior Football Pitch
WSM51	CLEVEDON GOLF CENTRE	Outdoor	Standard Golf Course
WSM52	CADBURY HOUSE HOTEL & LEISURE CLUB	Indoor	105 Stations, 2 Lane 20m Swimming Pool
WSM53	ST ANDREWS CHURCH OF ENGLAND JUNIOR SCHOOL	Outdoor	1 Junior Football Pitch
WSM54	CONGRESBURY CRICKET CLUB	Outdoor	1 Cricket Pitch
WSM55	BROADSTONE PLAYING FIELD	Outdoor	2 Football Pitches
WSM56	STRODE LEISURE CENTRE	Both	2 Football Pitches, 1 Junior Football Pitches, 25 Stations, 4 Badminton Courts, 6 Lane 25m Swimming Pool

Code	Name	Type	Facilities
WSM57	MENDIP SPRING GOLF CLUB	Outdoor	Standard Golf Course, Driving Range
WSM58	HAZELL CLOSE	Outdoor	2 Junior Football Pitches
WSM59	COLERIDGE VALE PLAYING FIELDS	Outdoor	1 Football Pitch, 1 Junior Football Pitch, 1 Junior Rugby Pitch, 4 Rugby Pitches
WSM60	CLEVEDON BOWLING CLUB	Indoor	2 Indoor Bowls Rinks
WSM61	THE HEALTH CLUB (CLEVEDON) LTD	Indoor	31 Stations
WSM62	SWISS VALLEY SPORTS CENTRE	Both	1 Cricket Pitch, 3 Football Pitches, 3 Rugby Pitches, 9 Stations, 5 Badminton Courts, 1 Floodlit Synthetic Pitch
WSM1	BLAGDON CRICKET CLUB	Outdoor	1 Cricket Pitch

9E.7.3 The Arup Sports Facilities audit does not cover areas outside of West Somerset and Sedgemoor.

b) Demand for Facilities

9E.7.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 218 non-home-based construction workers on average and 454 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise.

Table A9E.9: Sport England Sports Facilities Calculator Output: Weston-Super-Mare Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	2.09	4.35	2.83
	Lanes	0.04	0.08	0.05
	Pools	0.01	0.02	0.01
Halls	**Courts**	0.07	0.16	0.10
	Halls	0.02	0.04	0.03
Indoor Bowls	**Rinks**	0.01	0.02	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.01	0.02	

9E.7.5 The above table outlines demand for additional sports facilities, amounting to 0.01 swimming pools, 0.03 sports halls, 0.02 bowling rinks and 0.02 synthetic turf pitches. At present in the Weston-Super-Mare ward cluster, there is one 8-lane 25m indoor swimming pool at Hutton Leisure Centre, and this is considered adequate provision. There is also currently good provision of sports halls, pitches and bowling facilities identified by Sport England.

9E.8 Bridgwater Ward Cluster

9E.8.1 The Bridgwater ward cluster, to the south-east of HPC, covers the urban area of Bridgwater and smaller settlements of Westonzoyland to the east, North Petherton to the south and Wembdon.

a) Existing Facilities

9E.8.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.4**):

Table A9E.10: Sports Facilities in the Bridgwater Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
BR1	Eastover Park	Outdoor	1 Football Pitch
BR2	Trimwise	Indoor	40 Stations
BR3	YMCA	Both	1 Junior Football Pitch, 10 Stations, 1 Badminton Court
BR4	Robert Blake Science College	Both	1 Cricket Pitch, 1 Football Pitch, 1 Rugby Pitch, 4 Badminton Courts
BR5	Bridgwater Town FC	Outdoor	1 Football Pitch
BR6	Mansfield Park	Outdoor	2 Football Pitch
BR7	Bridgwater Indoor Bowls Club	Indoor	2 Indoor Bowls Rinks
BR8	Victoria Park	Outdoor	1 Football Pitch
BR9	Bridgwater Cricket Club	Outdoor	1 Cricket Pitch
BR10	Bridgwater College	Outdoor	2 Football Pitches, 29 Stations, 4 Badminton Courts, 1 Floodlit Synthetic Pitch
BR11	Drove House Health And Rehabilitation	Indoor	45 Stations
BR12	Bridgwater And Albion RFC	Outdoor	2 Rugby Pitches
BR13	Haygrove School Sports Field	Outdoor	1 Cricket Pitch
BR14	Bridgwater Sports And Social	Both	1 Cricket Pitch, 2 Football Pitches, 2 Indoor Bowls Rinks
BR15	East Bridgwater Sports Centre	Both	2 Football Pitches, 3 Rounders Pitches, 1 Rugby Pitch, 4 Badminton Courts
BR16	Haygrove School Sports Hall	Both	1 Football Pitch, 3 Rounders Pitches, 1 Rugby Pitch, 4 Badminton Courts
BR17	Chilton Trinity Sport And Leisure	Both	32 Stations, 4 Badminton Courts, 1 Floodlit Synthetic Pitch
BR18	Chilton Technology College	Outdoor	1 Cricket Pitch, 1 Football Pitch, 1 Junior Rugby Pitch, 3 Rounders Pitches
BR19	Wembdon Cricket Club	Outdoor	1 Cricket Pitch, 1 Football Pitch

BR20	Unique Health And Fitness	Indoor	14 Stations
BR21	Morganians RFC	Outdoor	2 Rugby Pitches
BR22	Westonzoyland Primary School	Outdoor	1 Junior Football Pitch
BR23	Westonzoyland Community Centre	Outdoor	1 Cricket Pitch, 1 Football Pitch
BR24	Westonzoyland Airfield	Outdoor	1 Football Pitch
BR25	North Petherton Cricket Club	Outdoor	1 Cricket Pitch
BR26	North Petherton	Outdoor	1 Football Pitch, 1 Junior Football Pitch
BR27	North Petherton RFC	Outdoor	3 Rugby Pitches

9E.8.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.5**).

Table A9E.11: Sports Facilities in the Bridgwater Ward Cluster (ARUP Audit, 2010)

Name	Sport
Trinity Hall	Badminton, Gymnastics
Hamp Community Junior School	Football (Youth) x3, Gymnastics
Chedzoy Village Hall	Gymnastics
Middlezoy Village Hall	Gymnastics, Martial Arts
Bawdrip Parish Hall	Gymnastics
Kingsmoor Primary School	Basketball, Football (Youth), Gymnastics, Netball
East Bridgwater Community School	Badminton, Basketball, Football (5-a-side), Football x2, Football (Youth), Gym, Gymnastics, Hockey, Squash x4
Moorland & District Village Hall	Gymnastics, Martial Arts
Othery Village Hall	Bowling
Lyng Village Hall	Gymnastics
Chilton Trinity Village Hall	Gymnastics
North Newton Village Hall	Gymnastics
Thurluxton Village Hall	Gymnastics, Martial Arts
Bridgwater Town Hall	Gymnastics
Sedgemoor Manor Community Nursery and Infant School	Athletics, Basketball, Football (Youth), Gymnastics, Netball
St Joseph's Roman Catholic Primary School	Athletics, Basketball, Gymnastics, Netball, Swimming
Haygrove School	Athletics, Badminton x3, Basketball x3, Football, Gym, Gymnastics, Hockey, Netball x3, Rugby, Tennis x2
St Mary's Church of England Primary School	Athletics, Football (Youth, Gymnastics, Netball
North Petherton Community Junior School	Athletics, Cricket, Gymnastics

Name	Sport
Wembdon St George's Primary School	Athletics, Gymnastics, Netball, Tennis
Robert Blake Science College	Athletics, Badminton x4, Basketball x3, Cricket x1, Football x2, Gym, Gymnastics, Hockey, Netball x2, Rugby x2, Tennis x3
North Petherton Community Centre	Gymnastics, Martial Arts
Durleigh Reservoir	Fishing, Sailing
Victoria Park	Football, Skate Park, Tennis x2
Church Road Play Area Wembdon	Basketball, Football
Eastover Park	Football, Skate Park
Ansons Way Play Area	Football
Whitfield Road Play Area	Basketball
Gloucester Road Play Area	Basketball
Crowpill Lane Play Area	Football
Dunwear Ponds	Fishing
Fore Street	Basketball, Football
North Lane Play Area	Basketball, Football (5-a-side)
Victoria Park Bowling Green	Bowling
Wembdon Cricket Club	Cricket, Football x2
Furze Close Cricket Pitch	Cricket
Middlezoy Sports Field	Basketball, Cricket, Football
Mansfield Park	Football
Parkersfield Close Sports Field	Football x2, Tennis x2
Cheer Lane Playing Field	Basketball, Cricket, Football
Bridgwater College Campus	Badminton x4, Basketball x3, Football (5-a-side) x3, Football x 2, Gym, Hockey
Bridgwater Rugby Club	Rugby x2
Bridgwater Town FC	Football
Bridgwater Cricket Club	Cricket x2
Bridgwater Bowling Club	Bowling x2
Bridgwater Sports and Social Club	Bowling, Cricket, Football (5-a-side), Football x2
Bridgwater YMCA	Basketball, Football (5-a-side), Football, Gymnastics, Martial Arts, Netball, Tennis x2
Eastover Park Bowling Club	Bowling
Eastover Tennis Centre	Tennis x4
Morgains Rugby Club	Football, Rugby
North Petherton Bowling Green	Bowling x2
North Petherton Cricket Club	Cricket

b) Demand for Facilities

9E.8.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 683 non-home-based construction workers on average and 1,422 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.12: Sport England Sports Facilities Calculator Output: Bridgwater Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	6.55	13.63	8.86
	Lanes	0.12	0.26	0.17
	Pools	0.03	0.06	0.04
Halls	**Courts**	0.23	0.49	0.32
	Halls	0.06	0.12	0.08
Indoor Bowls	**Rinks**	0.03	0.07	
	Centres	0.01	0.01	
Synthetic Pitches	**Pitches**	0.04	0.07	

9E.8.5 The above table outlines demand for additional sports facilities, amounting to 0.04 swimming pools, 0.08 sports halls, 0.07 bowling rinks and 0.07 synthetic turf pitches. At present in the Bridgwater ward cluster, there is a lack of swimming facilities provision, although there is good provision of indoor and outdoor sports facilities, notably at East Bridgwater Sports Centre, Bridgwater College and Chilton Trinity. In addition the proposed BRI-A accommodation campus will include the provision of sports pitches and a 20-station fitness suite, and there will be a new indoor swimming pool at Chilton Trinity.

9E.9 Hinkley Point/Stogursey Ward Cluster

9E.9.1 The Hinkley Point/Stogursey ward cluster, covers the ward which contains the proposed Hinkley Point C development.

a) Existing Facilities

9E.9.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.6**):

Table A9E.13: Sports Facilities in the Hinkley Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
HP1	Holford Cricket Club	Outdoor	1 cricket pitch not floodlit
HP2	Kilve Cricket Club	Outdoor	1 cricket pitch not floodlit

9E.9.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.7**).

Table A9E.14: Sports Facilities in the Hinkley Ward Cluster (ARUP Audit, 2010)

Code	Name	Name
HPa	Stogursey Victory Hall	Basketball, Football (5-a-side), Football, Gymnastics
HPb	Stogursey Primary School	Gymnastics, Netball
HPc	Stogursey Youth Club	Gymnastics
HPd	Holford Village Hall	Gymnastics, Martial Arts
HPe	Stogursey Church Rooms	Gymnastics, Martial Arts
HPf	Kilve Village Hall	Gymnastics, Martial Arts
HPg	Holford Play Area and MUGA	Basketball, Football (5-a-side) (MUGA)
HPh	Kilve Cricket Club	Cricket
HPi	Holford Cricket Ground	Cricket

b) Demand for Facilities

9E.9.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 248 non-home-based construction workers on average and 516 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.15: Sport England Sports Facilities Calculator Output: Hinkley Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	2.38	4.95	3.22
	Lanes	0.04	0.09	0.06
	Pools	0.01	0.02	0.02
Halls	**Courts**	0.09	0.18	0.12
	Halls	0.02	0.04	0.03
Indoor Bowls	**Rinks**	0.01	0.02	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.01	0.03	

9E.9.5 The above table outlines demand for additional sports facilities, amounting to 0.02 swimming pools, 0.03 sports halls, 0.02 bowling rinks and 0.03 synthetic turf pitches. At present in the Hinkley ward cluster, there is a lack of formal sports facilities due to few large settlements in the area. The provision of a new accommodation campus would include sports pitches and a 20-station health and fitness suite to cater for additional demand.

9E.10 Taunton Ward Cluster

9E.10.1 The Taunton ward cluster, covers the urban area of Taunton and surrounding areas of Bishop's Lydeard and Kingston St Mary.

a) Existing Facilities

9E.10.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.8**):

Table A9E.16: Sports Facilities in the Taunton Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
TA1	Bishops Lydreard Cricket Club	Outdoor	
TA2	Cedar Falls Health Spa	Both	9 hole golf course, 1 leisure pool, 1 lido
TA3	Bishops Lydeard AFC	Outdoor	4 pitches (3 full size football, 1 junior football)
TA4	Kingston St Mary Village Hall	Indoor	1 badminton court
TA5	Wellsprings Leisure Centre	Indoor	6 badminton courts
TA6	The Taunton Academy	Outdoor	2 full size football pitches
TA7	Taunton Green Playing Fields	Outdoor	4 pitches (1 full size football, 2 junior football, 1 cricket pitch)
TA8	Cotford St Luke Playing Field	Outdoor	
TA9	Norton Fitzwarren Playing Field	Outdoor	2 full size football pitches
TA10	Bishops Hull Playing Field	Outdoor	2 pitches (1 full size football, 1 cricket pitch)
TA11	Trull Cricket Club	Outdoor	1 cricket pitch not floodlit
TA12	Queens College Sports Centre	Both	15 pitches, 4 badminton courts, 4 lane swimming pool, 2 sand-based pitches)
TA13	Galmington Playing Fields	Outdoor	3 pitches (1 full-size football, 2 junior football)
TA14	Somerset College Of Arts And Technology	Both	1 full size football pitch, 4 badminton court
TA15	The Castle School	Outdoor	6 pitches
TA16	Castle Sports Centre	Both	6 lane athletics track, 4 badminton court, 1 rubber crumb pile 3G pitch)
TA17	Staplegrove Sports Ground	Outdoor	2 pitches (1 full size football, 1 cricket pitch)
TA18	Corkscrew Lane Playing Fields	Outdoor	2 full size football pitches
TA19	Taunton Vale Sports Club	Both	2 cricket pitches, 1 sandbased pitch

Code	Name	Type	Facilities
TA20	Taunton School Playing Fields	Outdoor	9 pitches inc rugby, hockey, cricket and 1 sandbased astro
TA21	Taunton School Sports Club	Both	5 pitches inc cricket, hockey, rugby, 5 badminton courts,5 lane swimming pool
TA22	Taunton Swimming Pool	Indoor	6 lane swimming pool
TA23	St James Street Baths	Indoor	2 pools - 1 main and 1 learner/teaching/training pool
TA24	Esporta Health And Fitness	Indoor	n/a
TA25	Taunton Bowling Club	Indoor	3 rinks
TA26	Taunton Dean Cricket Club	Outdoor	1 cricket pitch not floodlit
TA27	Wyvern Club	Outdoor	3 pitches (1 full-size football, 1 senior rugby union, 1 cricket)
TA28	Bishop Fox's School	Both	9 pitches inc rugby, hockey, cricket, football
TA29	Richard Huish College	Indoor	4 badminton courts
TA30	Kings College	Both	5 badminton courts, 6 lane swimming pool, 1 rubber crumb pile pitch
TA31	Kings College Astroturf Pitch	Outdoor	1 sand-based astro
TA32	Spirit Health Club	Indoor	4 lane swimming pool
TA33	Hamilton Gault Playing Field	Outdoor	4 pitches (2 full size football, 1 junior football, 1 cricket pitch)
TA34	Taunton Town Football Club	Outdoor	1 full size football pitch
TA35	Victoria Park Playing Fields	Outdoor	4 pitches (3 full size football, 1 cricket pitch)
TA36	Hermes Health And Fitness Studio	Indoor	n/a
TA37	The Taunton Academy 2	Indoor	1 badminton court
TA38	Priorswood Playing Field	Outdoor	4 pitches (2 full size football, 1 junior football, 1 cricket pitch)
TA39	Priorswood Playing Field (East)	Outdoor	1 full size football pitch
TA40	Taunton Rugby Club	Outdoor	3 senior rugby union pitches
TA41	Heathfield Community School	Both	4 badminton courts, 1 sand-based pitch
TA42	West Monkton Cricket Club	Outdoor	1 cricket pitch not floodlit
TA43	Creech St Michael Recreation Ground	Outdoor	1 full size football pitch

9E.10.3 The Arup Sports Facilities audit does not cover areas outside of West Somerset and Sedgemoor.

b) Demand for Facilities

9E.10.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 174 non-home-based construction workers on average and 362 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.17: Sport England Sports Facilities Calculator Output: Taunton Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	1.67	3.47	2.26
	Lanes	0.03	0.07	0.04
	Pools	0.01	0.02	0.01
Halls	**Courts**	0.06	0.12	0.08
	Halls	0.01	0.03	0.02
Indoor Bowls	**Rinks**	0.01	0.02	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.01	0.02	

The above table outlines demand for additional sports facilities, amounting to 0.01 swimming pools, 0.02 sports halls, 0.02 bowling rinks and 0.02 synthetic turf pitches. At present in the Taunton ward cluster, there is a good provision of indoor and outdoor sports pitches, halls and bowling facilities, along with a 6-lane swimming pool

9E.11 Burnham / Highbridge Ward Cluster

9E.11.1 The Burnham / Highbridge ward cluster includes the coastal settlements of Highbridge and Burnham-on-Sea to the north-east of Bridgwater.

a) Existing Facilities

9E.11.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.9**):

Table A9E.18: Sports Facilities in the Burnham/Highbridge Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
BH1	ISLE OF WEDMORE GOLF CLUB	Outdoor	18 Hole Standard Golf Course
BH2	WEDMORE RECREATION GROUND	Outdoor	1 Cricket Pitch, 1 Football Pitch, 1 Junior Football Pitch
BH3	HUGH SEXEY CHURCH OF ENGLAND MIDDLE SCHOOL	Indoor	1 Badminton Court
BH4	PRIORY MARK COLLEGE	Indoor	4 Badminton Courts

Code	Name	Type	Facilities
BH5	PRIORY MARK COLLEGE PITCHES	Outdoor	1 Cricket Pitch, 1 Football Pitch, 2 Junior Rugby Pitches
BH6	MARK CRICKET CLUB AND FOOTBALL FIELD	Outdoor	1 Cricket Pitch, 1 Junior Football Pitch
BH7	EAST HUNTSPILL RECREATION GROUND	Outdoor	1 Cricket Pitch, 1 Football Pitch
BH8	EAST HUNTSPILL CRICKET GROUND	Outdoor	1 Cricket Pitch
BH9	HIGHER PLAYING FIELD WOOLAVINGTON	Outdoor	1 Football Pitch
BH10	R M SMITH PLAYING FIELD	Outdoor	1 Football Pitch
BH11	PURITON PLAYING FIELDS	Both	1 Cricket Pitch, 1 Football Pitch, 2 Bowls Rinks
BH12	PAWLETT PLAYING FIELD	Outdoor	1 Cricket Pitch, 1 Football Pitch, 1 Junior Football Pitch
BH13	THE WAR MEMORIAL GROUND	Outdoor	2 Cricket Pitch, 1 Football Pitch, 1 Junior Football Pitch, 1 Rounders Pitch
BH14	LYMPSHAM SPORTS CLUB	Outdoor	1 Cricket Pitch
BH15	BURNHAM AND BERROW GOLF CLUB	Outdoor	18 Hole Standard Golf Course, 9 Hole Standard Golf Course
BH16	BURNHAM ASSOCIATION SPORTS CLUB	Outdoor	1 Cricket Pitch, 1 Football Pitch, 2 Junior Rugby Pitches, 3 Senior Rugby Pitches
BH17	BURNHAM ON SEA SWIM AND SPORTS ACADEMY	Indoor	4 Lane 25m Swimming Pool
BH18	FIT 4 ALL HEALTH AND FITNESS STUDIO	Indoor	60 Stations
BH19	FUSION LEISURE CENTRE	Indoor	21 Stations, 15m Swimming Pool
BH20	BURNHAM GOLF RANGE	Outdoor	Driving Range
BH21	HIGHBRIDGE RECREATION GROUND	Outdoor	1 Football Pitch
BH22	THE KING ALFRED SCHOOL	Outdoor	1 Cricket Pitch, 2 Football Pitches, 1 Rounders Pitch, 2 Senior Rugby Pitches
BH23	KING ALFRED SPORTS CENTRE (HIGHBRIDGE)	Both	26 Stations, 4 Badminton Courts, 1 Floodlit Synthetic Pitch
BH24	BURNHAM ROAD PLAYING FIELD	Outdoor	4 Football Pitches, 1 Junior Football Pitch
BH25	RED ROAD PLAYING FIELDS	Outdoor	3 Football Pitches, 1 Junior Football Pitch
BH26	BREAN GOLF CLUB	Outdoor	1 Standard, 1 Par3

9E.11.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.10**).

Table A9E.19: Sports Facilities in the Burnham/Highbridge Ward Cluster (ARUP Audit, 2010)

Code	Name	Facilities
BHa	Puriton Village Hall	Martial Arts
BHb	Mark Village Hall	Bowling, Gymnastics
BHc	Woolavington Village Hall	Gymnastics, Martial Arts
BHd	Woolavington Primary School	Athletics, Basketball, Football (Youth), Gymnastics
BHe	Puriton Primary School	Football (Youth), Gymnastics, Netball
BHf	Edington Village Hall	Gymnastics
BHg	Cossington Village Hall	Gymnastics
BHh	Burtle Village Hall	Gymnastics, Martial Arts
BHi	St Andrew's Church of England School	Athletics, Basketball, Football (Youth), Gymnastics, Netball
BHj	St Joseph's Primary School	Football (Youth), Gymnastics
BHk	East Huntspill Village Hall	Gymnastics
BHl	Watchfield Hall	Gymnastics
BHm	Brent Knoll Parish Hall	Gymnastics
BHn	East Brent Village Hall	Bowling, Gymnastics, Martial Arts
BHo	Manor Hall	Gymnastics
BHp	Catcott Primary School	Football (5-a-side), Football (Youth), Gymnastics
BHq	Wedmore Village Hall	Badminton, Gymnastics
BHr	Wedmore Primary School	Athletics, Football (Youth), Gymnastics, Swimming
BHs	Brent Knoll Primary School	Athletics, Football (Youth), Gymnastics, Netball
BHt	East Brent C of E Primary School	Gymnastics
BHu	The King Alfred Secondary School	Athletics, Badminton x3, Basketball x3, Cricket, Football, Gymnastics, Hockey, Netball x3, Rugby, Tennis x11

BHuuu	Brean Golf Club	Golf

b) Demand for Facilities

9E.11.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 181 non-home-based construction workers on average and 378 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.20: Sport England Sports Facilities Calculator Output: Burnham / Highbridge Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	1.74	3.62	2.36
	Lanes	0.03	0.07	0.04
	Pools	0.01	0.02	0.01
Halls	**Courts**	0.06	0.13	0.08
	Halls	0.02	0.03	0.02
Indoor Bowls	**Rinks**	0.01	0.02	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.01	0.02	

9E.11.5 The above table outlines demand for additional sports facilities, amounting to 0.01 swimming pools, 0.02 sports halls, 0.02 bowling rinks and 0.02 synthetic turf pitches. At present in the Burnham / Highbridge ward cluster, there is a wide provision of indoor and outdoor sports pitches including cricket and football provision, halls, athletics and bowling facilities, although a lack of formal indoor swimming.

9E.12 Glastonbury Ward Cluster

9E.12.1 The Glastonbury ward cluster includes the urban area of Glastonbury and surrounding villages and countryside, including Street and Somerton.

a) Existing Facilities

9E.12.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.11**):

Table A9E.21: Sports Facilities in the Glastonbury Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
GL1	LONG SUTTON GOLF CLUB	Outdoor	1 Standard Golf Course, Driving Range
GL2	LONG SUTTON	Outdoor	1 Cricket Pitch, 1 Football Pitch
GL3	SOMERTON SPORTS FIELD	Outdoor	1 Cricket Pitch, 3 Football Pitches, 1 Junior Football Pitch, 1 Rounders Pitch, 1 Rugby Pitch
GL4	PITNEY PLAYING FIELD	Outdoor	1 Cricket Pitch, 1 Football Pitch
GL5	HIGH HAM PLAYING FIELD	Outdoor	1 Junior Football Pitch
GL6	COMPTON DUNDON CRICKET CLUB	Outdoor	1 Cricket Pitch
GL7	MILLFIELD SENIOR SCHOOL SPORTS FACILITIES	Both	1 6-Lane Athletics Track, 6 Cricket Pitches, 10 Football Pitches, 7 Rugby Pitches, 3 Indoor Tennis Courts, 5 Badminton Courts, 1 8-Lane 50m Swimming Pool, 1 Floodlit Synthetic Pitch
GL8	STRODE COLLEGE SPORTS CENTRE	Both	1 Football Pitch, 4 Badminton Courts, 1 Floodlit 3G Synthetic Pitch
GL9	CRISPIN COMMUNITY SCHOOL	Both	2 Football Pitches, 2 Hockey Pitches, 1 Rounders Pitch, 2 Rugby Pitches, 5 Badminton Courts
GL10	STRODE SWIMMING POOL	Indoor	34 Stations, 6 Lane 33.3m Swimming Pool
GL11	GREENBANK SWIMMING POOL	Outdoor	1 32m Lido
GL12	ELMHURST JUNIOR SCHOOL	Outdoor	1 Cricket Pitch, 1 Junior Football Pitches, 3 Rounders Pitches
GL13	VICTORIA FIELD SPORTS AND SOCIAL CLUB	Both	1 Cricket Pitch, 1 Football Pitch, 2 Rounders Pitches
GL14	BROOKSIDE COMMUNITY PRIMARY SCHOOL	Outdoor	1 Junior Football Pitch
GL15	SHAPWICK SCHOOL (SHAPWICK SENIOR)	Indoor	3 Badminton Courts
GL16	ASHCOTT AND SHAPWICK CRICKET CLUB	Outdoor	1 Cricket Pitch
GL17	MEARE & WEST HAY PLAYING FIELDS	Outdoor	1 Cricket Pitch, 2 Football Pitches
GL18	WALTON VILLAGE HALL	Both	1 Cricket Pitch, 1 Football Pitch, 1 Badminton Court
GL19	TOR LEISURE CENTRE	Outdoor	2 Cricket Pitches, 3 Football Pitches, 8 Junior Football Pitches, 6 Rounders Pitches

Code	Name	Type	Facilities
GL20	TRAIN STATION HEALTH AND FITNESS (GLASTONBURY)	Indoor	61 Stations

9E.12.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.12**).

Table A9E.22: Sports Facilities in the Glastonbury Ward Cluster (ARUP Audit, 2010)

Code	Name	Facilities
GLa	Ashcott Village Hall	Badminton, Bowling, Martial Arts
GLb	Ashcott Primary School	Athletics, Gymnastics
GLc	Shapwick Village Hall	Gymnastics
GLd	Shapwick School	Athletics, Badminton, Basketball, Cricket, Football x2, Gymnastics, Rugby x2, Tennis
GLe	Ashcott Playing Field	Football x2, Tennis
GLf	Ashcott and Shapwick Cricket Ground	Cricket

b) Demand for Facilities

9E.12.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 39 non-home-based construction workers on average and 81 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.23: Sport England Sports Facilities Calculator Output: Glastonbury Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.78	0.37	0.50
	Lanes	0.01	0.01	0.01
	Pools	0.00	0.00	0.00
Halls	**Courts**	0.03	0.01	0.02
	Halls	0.01	0.00	0.00
Indoor Bowls	**Rinks**	0.00	0.00	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.00	

9E.12.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.00 sports halls, 0.00 bowling rinks and 0.00 synthetic turf pitches. At present in the Glastonbury ward cluster, there is a good provision of indoor and outdoor sports pitches, halls and bowling facilities, and potentially accessible swimming facilities.

9E.13 Watchet /Williton Cluster

9E.13.1 The Watchet / Williton ward cluster includes the urban area of Glastonbury and surrounding villages and countryside, including Street and Somerton.

a) Existing Facilities

9E.13.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.13**):

Table A9E.24: Sports Facilities in the Watchet/Williton Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
WW2	Watchet War Memorial Ground	Outdoor	3 pitches (1 full size football, 1 junior football, 1 cricket pitch)
WW3	Watchet Indoor Bowling Club	Indoor	1 rink
WW4	The Knights Templar School	Indoor	Learning/teaching/training
WW5	Danesfield Coe Community Middle School	Both	3 grass pitches (1 junior football, 1 junior rugby union, 1 cricket pitch) and 1 badminton court
WW6	Williton Memorial Ground	Outdoor	2 pitches (both full size football)
WW7	Stogumber Cricket Club	Outdoor	1 cricket pitch not floodlit
WW8	Crowcombe Cricket Club	Outdoor	2 pitches (1 junior football, 1 cricket pitch)
WW9	Roadwater Cricket Club	Outdoor	1 cricket pitch not floodlit
WW10	Hoburne Blue Anchor Caravan Park	Outdoor	Leisure pool

9E.13.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.14**).

Table A9E.25: Sports Facilities in the Watchet/Williton Ward Cluster (ARUP Audit, 2010)

Code	Name	Facilities
WWa	East Quantoxhead Village Hall	Gymnastics
WWb	Washford Memorial Hall	Gymnastics, Martial Arts
WWc	Old Cleeve Community Hall	Badminton, Bowling
WWd	Stogumber Village Hall	Bowling, Football (Youth), Gymnastics
WWe	Sandford Brett Village Hall	Gymnastics
WWf	Watchet Youth Club	Football (Youth), Gymnastics
WWg	Danesfield Church of England Middle School	Athletics x2, Basketball, Football (5-a-side), Football, Gym, Gymnastics, Hockey, Martial Arts, Netball x3, Tennis x4
WWh	Bicknoller Village Hall	Gymnastics, Martial Arts
WWi	St Audries Village Hall	Gymnastics, Martial Arts
WWj	Watchet Boxing Club	Boxing

WWk	Watchett Marina	Sailing
WWl	Bicknoller Play Area	Basketball, Football (5-a-side)
WWm	Williton Recreation Ground	Football
WWn	Watchett Memorial Playing Field	Basketball, Cricket, Football (5-a-side), Football x2, Tennis x2
WWo	Henry Davey Playing Field	Basketball, Football (Youth) x2, Skate Park
WWp	Watchet Bowling Green	Bowling
WWq	Kesteven Recreation Ground	Cricket x2, Tennis
WWr	Stogumber Cricket Club	Cricket
WWs	Wiliton Bowling Club	Bowling

b) Demand for Facilities

9E.13.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 72 non-home-based construction workers on average and 150 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.26: Sport England Sports Facilities Calculator Output: Watchet/ Williton Ward Cluster

Sports Facilities Calculator				
		27 Months	**64 Months**	**Permanent Equivalent**
Pools	**Area**	0.69	1.44	0.93
	Lanes	0.01	0.03	0.02
	Pools	0.00	0.01	0.00
Halls	**Courts**	0.02	0.05	0.03
	Halls	0.01	0.01	0.01
Indoor Bowls	**Rinks**	0.00	0.01	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.01	

9E.13.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.01 sports halls, 0.01 bowling rinks and 0.01 synthetic turf pitches. At present in the Watchet / Williton ward cluster, there is a good provision of bowling facilities and some indoor and outdoor sports pitches / halls, but a lack of formal indoor swimming facilities.

9E.14 Cheddar Ward Cluster

9E.14.1 The Cheddar ward cluster includes the urban area of Cheddar and Axbridge and surrounding villages and countryside, and is bisected by the A38 and A371.

a) Existing Facilities

9E.14.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.15**):

Table A9E.27: Sports Facilities in the Cheddar Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
CH1	WEBBINGTON HOTEL LEISURE CLUB	Indoor	29 Stations
CH2	ALLERTON CRICKET CLUB	Outdoor	1 Cricket Pitch
CH3	CHEDDAR FOOTBALL CLUB	Outdoor	1 Football Pitch
CH4	FAIRLANDS MIDDLE SCHOOL	Both	1 Cricket Pitch, 1 Rounders Pitch
CH5	KINGS FITNESS AND LEISURE	Indoor	29 Stations
CH6	SHARPHAM ROAD PLAYING FIELDS	Outdoor	1 Cricket Pitch, 1 Football Pitch, 1 Junior Football Pitch, 1 Rugby Pitch
CH7	THE FURLONG	Outdoor	1 Football Pitch

9E.14.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.16**):

Table A9E.28: Sports Facilities in the Cheddar Ward Cluster (ARUP Audit, 2010)

Code	Name	Facilities
CHa	Shipham Village Hall	Badminton, Gymnastics, Martial arts
CHb	Axbridge Town Hall	Martial Arts
CHc	Badgworth & Biddisham Hall	Gymnastics
CHd	Cross Memorial Hall	Gymnastics
CHe	Old School Rooms Allerton	Gymnastics
CHf	Axbridge Youth Club	Basketball, Football (5-a-side)
CHg	The Kings of Wessex Community School	Athletics, Badminton x3, Cricket, Gymnastics, Hockey, Rugby
CHh	Fairlands Middle School	Athletics, Cricket, Football, Gymnastics, Netball x5, Tennis x5
CHi	Shipham Church of England First School	Athletics, Football (Youth), Gymnastics, Netball
CHj	King of Wessex Leisure Centre	Badminton x3, Basketball x3, Football (5-a-side), Gym x3, Gymnastics, Hockey, Martial Arts, Squash x2, Swimming, Tennis x4
CHk	Penn Way Recreation Ground	Football x3, Football (youth) x1
CHl	War Memorial Playing Field	Cricket, Football
CHm	Cheddar Reservoir	Fishing

Code	Name	Facilities
CHn	Cheddar Lawn Tennis Club	Tennis x4
CHo	Cheddar Valley Rugby Club	Rugby x2
CHp	Sharpham Road Playing Field	Cricket, Football x3
CHq	Cheddar FC Sports and Social	Football
CHr	Bristol Corinthian Yacht Club	Sailing
CHs	Shipham Sports Field	Football
CHt	Allerton Cricket Ground	Cricket

b) Demand for Facilities

9E.14.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 34 non-home-based construction workers on average and 70 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.29: Sport England Sports Facilities Calculator Output: Cheddar Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.33	0.67	0.44
	Lanes	0.01	0.01	0.01
	Pools	0.00	0.00	0.00
Halls	**Courts**	0.01	0.02	0.02
	Halls	0.00	0.01	0.00
Indoor Bowls	**Rinks**	0.00	0.00	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.00	

9E.14.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.00 sports halls, 0.00 bowling rinks and 0.00 synthetic turf pitches. At present in the Cheddar ward cluster, there is a good provision of sports halls, pitches and swimming, for example at King of Wessex Leisure Centre and Churchill Sports Centre.

9E.15 Somerset South Ward Cluster

9E.15.1 The Somerset South ward cluster includes the area to the south-east of Taunton, including the settlements of Wellington and Ilminster.

a) Existing Facilities

9E.15.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.17**):

Table A9E.30: Sports Facilities in the Somerset South Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
SS1	STOKE ST GREGORY PLAYING FIELD	Outdoor	1 cricket pitch not floodlit
SS2	CURRY RIVAL CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SS3	WESTFIELD RECREATION GROUND	Outdoor	2 pitches (1 full size football pitch, 1 junior football pitch)
SS4	ILTON CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SS5	FIVEHEAD PLAYING FIELD	Both	2 pitches (1 full size football pitch, 1 junior football pitch), 1 badminton court hall
SS6	GREENWAY PLAYING FIELD PAVILION	Outdoor	1 full size football pitch
SS7	TAUNTON VALE GOLF COURSE	Outdoor	1 driving range and 2 18 hole courses
SS8	SWINGRATE GOLF CENTRE	Outdoor	1 driving range and 1 par 3
SS9	STOKE ST MARY CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SS10	TAUNTON AND PICKERIDGE GOLF CLUB	Outdoor	18 hole golf course
SS11	CHURCHINFORD SPORT CLUB	Outdoor	2 pitches (1 full size football pitch, 1 cricket pitch)
SS12	PITMINSTER & ANGERSLEIGH PLAYING FIELDS	Outdoor	1 full size football pitch
SS13	SAMPFORD ARUNDEL CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SS14	DOBREE PARK	Outdoor	1 full size football pitch
SS15	BODYWISE HEALTH AND FITNESS SPA	Indoor	n/a
SS16	COURT FIELDS COMMUNITY SCHOOLS	Both	3 pitches (1 full size football, 1 junior football, 1 cricket pitch), 4 badminton court hall

Code	Name	Type	Facilities
SS17	THE PRINCESS ROYAL SPORTS COMPLEX	Both	6 badminton courts, 1 sand-based pitch
SS18	WELLINGTON RECREATION GROUND	Outdoor	2 pitches (1 full size football and 1 junior football)
SS19	WELLINGTON PLAYING FIELD	Outdoor	4 pitches (1 full size football, 1 senior rugby union, 1 junior football, 1 cricket pitch)
SS20	WELLINGTON SPORTS CENTRE	Indoor	4 badminton court hall, 6 lane swimming pool
SS21	WELLINGTON RUGBY CLUB	Outdoor	2 senior rugby union

9E.15.3 The Arup Sports Facilities audit does not cover areas outside of West Somerset and Sedgemoor.

b) Demand for Facilities

9E.15.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 27 non-home-based construction workers on average and 55 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.31: Sport England Sports Facilities Calculator Output: Somerset South Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.26	0.53	0.34
	Lanes	0.00	0.01	0.01
	Pools	0.00	0.00	0.00
Halls	**Courts**	0.01	0.02	0.01
	Halls	0.00	0.00	0.00
Indoor Bowls	**Rinks**	0.00	0.00	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.00	

9E.15.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.00 sports halls and 0.00 synthetic turf pitches. At present in the Somerset South ward cluster, there is a good level of playing pitch provision and sports halls / courts and bowling rinks, and there is a 6-lane swimming pool at Wellington Sports Centre.

9E.16 Somerset West Ward Cluster

9E.16.1 The Somerset West ward cluster includes the area to the west of Taunton, including the southern section of Exmoor National Park and small settlements including Milverton and Wiveliscombe.

a) Existing Facilities

9E.16.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.18**):

Table A9E.32: Sports Facilities in the Somerset West Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
SW1	WINSFORD VILLAGE HALL	Indoor	1 badminton court
SW3	BRIDGTOWN CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SW2	WINSFORD RECREATION GROUND	Outdoor	1 cricket pitch not floodlit
SW4	ASHBRITTLE CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SW5	KINGSMEAD COMMUNITY SCHOOL	Indoor	4 badminton courts
SW6	WIVELISCOMBE RECREATION GROUND	Both	3 pitches (1 senior rugby union, 1 junior rugby union, 1 cricket pitch) and 1 lido
SW7	BROMPTON RALPH CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SW8	LYDEARD ST LAWRENCE CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SW9	FITZHEAD CRICKET CLUB	Outdoor	1 cricket pitch not floodlit
SW10	MILVERTON RECREATION GROUNDS	Outdoor	2 pitches (1 full size football, 1 cricket pitch)
SW11	OAKE MANOR GOLF CLUB	Outdoor	Driving range and standard golf course
SW12	HILLVIEW GROUND	Outdoor	1 full size football pitch
SW13	BAGBOROUGH CRICKET CLUB	Outdoor	1 cricket pitch not floodlit

9E.16.3 The Arup Sports Facilities audit does not cover areas outside of West Somerset and Sedgemoor.

b) Demand for Facilities

9E.16.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 9 non-home-based construction workers on average and 19 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise.

Table A9E.33: Sport England Sports Facilities Calculator Output: Somerset West Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.09	0.18	0.12
	Lanes	0.00	0.00	0.00
	Pools	0.00	0.00	0.00
Halls	**Courts**	0.00	0.01	0.00
	Halls	0.00	0.00	0.00
Indoor Bowls	**Rinks**	0.00	0.00	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.00	

The above table outlines demand for additional sports facilities, amounting to less than 0.00 swimming pools, less than 0.00 sports halls and less than 0.00 synthetic turf pitches. At present in the Somerset West ward cluster, there are several facilities that include indoor and outdoor halls and pitches, although no swimming facilities.

9E.17 Cannington Ward Cluster

9E.17.1 The Cannington ward cluster, to the south-east of Hinkley C, covers a single ward between the site and the closest large settlement of Bridgwater. It includes the smaller settlement of Cannington.

a) Existing Facilities

9E.17.2 An audit of existing sport and leisure facilities, using Sport England's Active Places website, has identified the following existing sports facilities in the area (See **Figure 2.19**):

Table A9E.34: Sports Facilities in the Cannington Ward Cluster (Sport England Active Places, 2011)

Code	Name	Type	Facilities
CA2	Over Stowey Cricket Club	Outdoor	1 cricket pitch not floodlit
CA3	Quantock Lodge	Indoor	5 badminton courts, 6 lane pool
CA4	Spaxton Village Hall Playing Field	Outdoor	3 pitches (2 full size football, 1 cricket pitch)
CA5	Enmore Park Golf Club	Outdoor	18 hole golf course
CA6	Cannington Playing Field	Outdoor	3 pitches (1 full size football, 1 senior rugby union, 1 cricket pitch)
CA7	Cannington Golf Centre	Outdoor	1 driving range and a 9 hole course

9E.17.3 In addition, the following sports facilities were identified by ARUP through their sports and leisure facilities audit (See **Figure 2.20**).

Table A9E.35: Sports Facilities in the Cannington Ward Cluster (ARUP Audit, 2010)

Code	Name	Facilities
CAa	Enmore Memorial Hall	Badminton
CAb	St Mary's Church Centre	Badminton
CAc	Nether Stowey Primary School	Football (Youth), Gym, Gymnastics
CAd	Nether Stowey Village Hall	Gymnastics
CAe	Brymore Boarding School	Basketball, Cricket, Football (5-a-side), Football x2, Gym, Hockey, Rugby x2, Swimming
CAf	Otterhampton Primary School	Football (Youth), Gymnastics, Netball
CAg	Otterhampton Village Hall	Bowling
CAh	Spaxton Church of England School	Football (Youth), Gymnastics, Netball
CAi	Cannington Youth Club	Gymnastics
CAj	Quantock Lodge Leisure Centre	Gym, Swimming
CAk	Fiddington Play Area	Football (Youth)
CAl	Spaxton Village Play Area	Cricket, Football x2, Football (Youth)
CAm	Hawkridge Reservoir	Fishing, Sailing
CAn	Cannington Play Area	Football (Youth)
CAo	Combwich Common	Football
CAp	Combwich Fishing Lake	Fishing
CAq	Over Stowey Cricket and Tennis Field	Cricket
CAr	Enmore golf club	Golf
CAs	Cannington Sports Field	Football
CAt	Cannington Pitch and Putt	Golf
CAu	Cannington Golf Course	Golf
CAv	Bridgwater College Cannington Campus	Cricket, Football x2, Rugby x2

b) Demand for Facilities

9E.17.4 Based on the latest version of the Gravity Model, the wards that make up this cluster are expected to accommodate 58 non-home-based construction workers on average and 120 non-home-based construction workers at peak. Using Sport England's Sports Facility Calculator (see main report for methodology notes), the following demands are estimated to arise:

Table A9E.36: Sport England Sports Facilities Calculator Output: Cannington Ward Cluster

Sports Facilities Calculator				
		27 Months	64 Months	Permanent Equivalent
Pools	**Area**	0.56	1.15	0.75
	Lanes	0.01	0.02	0.01
	Pools	0.00	0.01	0.00
Halls	**Courts**	0.02	0.04	0.03
	Halls	0.00	0.01	0.01
Indoor Bowls	**Rinks**	0.00	0.01	
	Centres	0.00	0.00	
Synthetic Pitches	**Pitches**	0.00	0.01	

9E.17.5 The above table outlines demand for additional sports facilities, amounting to 0.00 swimming pools, 0.01 sports halls and 0.01 synthetic turf pitches. At present in the Cannington ward cluster, there are several indoor and outdoor facilities, with potentially a lack of indoor courts and public swimming facilities.

APPENDIX 9F: SOCIO-ECONOMIC TECHNICAL NOTE 6: COMMUNITY COHESION

FOREWORD

The National Policy Statements for Energy (EN-1) and specifically for proposed nuclear developments (EN6) identify issues which should be addressed by those proposing developments. These issues include the "significant social and economic impacts of the development" including how any significant negative impacts would be mitigated.

This note focuses on the specific dimension of "community cohesion". It identifies a working definition of community cohesion, and reviews current and recent community cohesion issues in the South West, which already has a substantial migrant workforce. It then identifies how EDF Energy will seek to deal with these issues in the context of the wider socio-economic strategy, and mitigation of development impacts.

9F. APPENDIX 9F: SOCIO-ECONOMIC TECHNICAL NOTE 6: COMMUNITY COHESION

9F.1 Context

9F.1.1 The National Policy Statements for Energy (NPS EN-1) (Ref. 9F.1) and specifically for proposed nuclear developments (NPS EN-6) (Ref. 9F.2) identify issues which should be addressed by those proposing developments.

9F.1.2 EN-1 states:

> *"While not required by the EIA Directive, the IPC will find it helpful if the applicant also sets out information on the likely significant social and economic effects of the development, and shows how any likely significant negative effects would be avoided or mitigated. This information could include matters such as employment, equality, community cohesion and well-being."*

9F.1.3 EDF Energy's evidence base for the impacts of the proposed development at Hinkley Point C is based on a technical evidence base produced by the Impact Assessment Unit at Oxford Brookes University, and a series of Technical Notes which provide more detailed assessments on specific topic areas.

9F.1.4 Technical Note 1 identifies the likely workforce required to construct Hinkley Point C and the likely labour market catchment areas. Technical Note 2 identifies the likely demographic breakdown of the workforce including, age, gender and household types. It also identifies the proportions of non-UK nationals and Black and Minority Ethnic (BAME) communities in the UK and South West workforces. Technical Note 3 sets out research findings on the Spatial Distribution of the Construction Workforce.

9F.1.5 This note focuses on the specific dimension of "*community cohesion*". It identifies a working definition of community cohesion, and reviews current and recent community cohesion issues in the South West, which already has a substantial migrant workforce. It then identifies how EDF Energy will seek to deal with these issues in the context of the wider socio-economic strategy, and mitigation of development impacts.

9F.2 Definitions of Community Cohesion

9F.2.1 The Local Government Association (LGA) first defined Community Cohesion as a starting point for councils in 2002 as part of the national response to the disturbances in Burnley, Bradford and Oldham in 2001:

"A cohesive community is one where:

- There is common vision and a sense of belonging for all communities.
- The diversity of people's different backgrounds and circumstances are appreciated and positively valued.
- Those from different backgrounds have similar life opportunities.
- Strong and positive relationships are being developed between people from different backgrounds in the workplace, in schools and within neighbourhoods." (Ref. 9F.3).

9F.2.2 As work and thinking about community cohesion has developed, there have been other definitions. The Commission for Integration and Cohesion (Ref. 9F.4) in 2007 defined an integrated and cohesive community as one with:

- "A defined and widely shared sense of the contribution of different individuals and groups to a future local or national vision.
- A strong sense of an individual's local rights and responsibilities.
- A strong sense that people with different backgrounds should experience similar life opportunities and access to services and treatment.
- A strong sense of trust in institutions locally, and trust that they will act fairly when arbitrating between different interests and be subject to public scrutiny.
- A strong recognition of the contribution of the newly arrived, and of those who have deep attachments to a particular place – focusing on what people have in common.
- Positive relationships between people from different backgrounds in the workplace, schools and other institutions."

9F.2.3 More recently, in 2008, the Department for Communities and Local Government (Ref. 9F.5) stated that:

"Community Cohesion is what must happen in all communities to enable different groups of people to get on well together. A key contributor to community cohesion is integration which is what must happen to enable new residents and existing residents to adjust to one another.

"Our vision of an integrated and cohesive community is based on three foundations:

- People from different backgrounds having similar life opportunities.
- People knowing their rights and responsibilities.
- People trusting one another and trusting local institutions to act fairly".

9F.2.4 Up until 2010 councils were required to measure if residents felt that people from different backgrounds got on well together, as part of the national audit and inspection process. Many councils have developed their own local definitions of cohesion to reflect their local issues. This is likely to evolve in the context of the Government's plans for the "Big Society" aimed at achieving greater decentralisation and participation as set out in the Localism Bill. (Ref. 9F.6).

9F.3 Migration in the South West

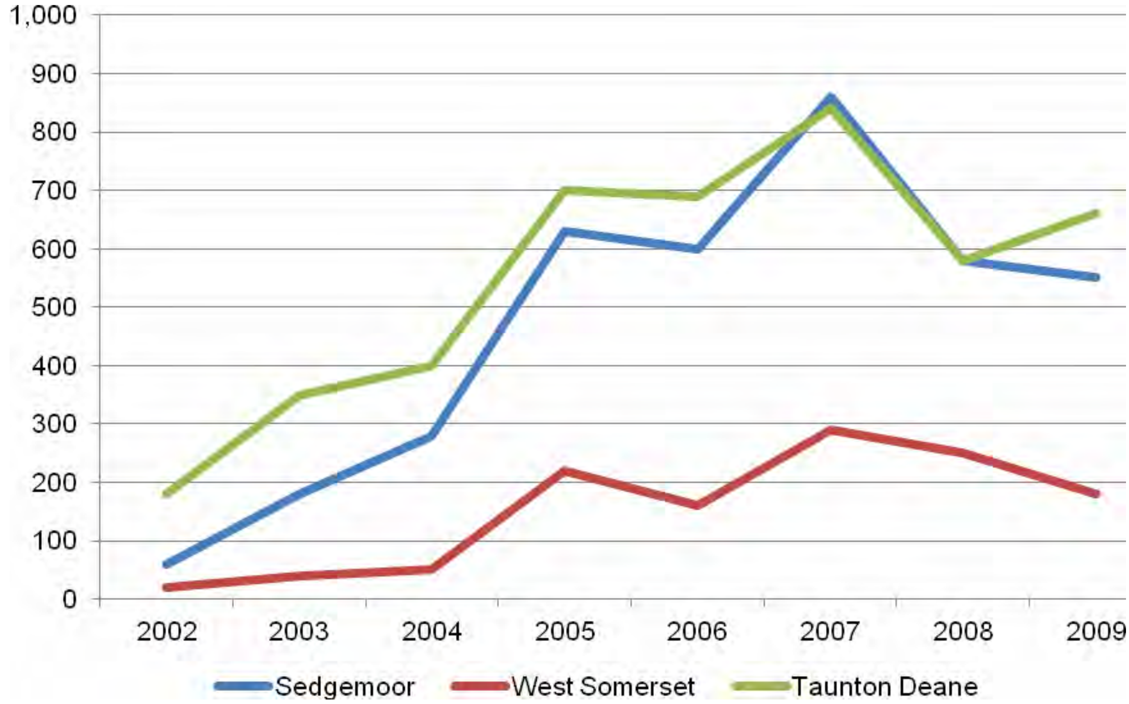
9F.3.1 The South West region sees significant annual population turnover. Like most places "internal migration", that is migration from elsewhere in the UK, significantly outweighs international migration. The most recent data shows a net gain of around 19,000 residents in 2009/10 from within the UK and a net loss of population from international migration of 3,850 in 2008/9 (Ref. 9F.7).

9F.3.2 For the most recent year for which figures are available (2008-2009) Government migration data suggests that around 12,000 people moved in to the three districts (Sedgemoor, Taunton Deane and West Somerset) and around 11,000 people moved out. The area also sees significant seasonal tourism inflows with around 5 million overnight visitors a year.

9F.3.3 The 2001 Census data suggested that the south-west had a small ethnic minority population, with 97% being classified as white British or Irish. (Ref. 9F.8) Although 2011 census data is not yet available it is clear that that figure will have increased, particularly since EU enlargement in 2004. This gave residents of the eight "accession states" (known as the A8: Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, and Slovenia) the right to live and work in the UK.

9F.3.4 The **Plate A9F.1** below shows the number of National Insurance Number (NINO) registrations for foreign national adults in the three districts covered by the HPC assessments. (Ref. 9F.9) These numbers do not track the numbers who become permanent residents or the duration of their stay. Many will be temporary seasonal workers. They do however demonstrate a clear upward trend from the early 2000s, particularly after 2004, which appears to have fallen since the onset of the recession. However, in the context of annual migration figures described above they still form a minority of migration to the south west.

Plate A9F.1: Total Number of National Insurance Number Registrations by Foreign National Adults by Year in the Three Districts (Sedgemoor, West Somerset and Taunton Deane)



9F.3.5 Research published by the Institute of Fiscal Studies suggests that, contrary to popular perception, migrant workers from A8 Accession countries make a net fiscal contribution to the UK Exchequer. (Ref. 9F.10) This is because they are almost all in work, and have lower take up of benefits and public services, partly as they are younger and less likely to have dependents. An analysis of social housing lettings data in 2006/7, the peak year for migration, shows only 55 lettings across the entire south-west compared to over 20,000 A8 workers being registered under the NINO scheme in the region over the same period. (Ref. 9F.11).

9F.3.6 In this context it is important to bear in mind that, although the research on community cohesion has focussed on black and minority or foreign migrants, they are not the only, or even the main cause of population turnover or transience in an area. Therefore whilst some of the issues identified (e.g. language problems) are specific to an international migrant workforce, many can also be addressed by more general actions required to manage a construction workforce.

9F.4 Research on Community Cohesion in the South West

9F.4.1 One of the earliest local studies into migrant workers in the South West was conducted by **South Somerset District Council**. (Ref. 9F.12) This project was one of the first pieces of primary survey research into migrant workers by any Local Authority. The aim of this study was to examine the diversity and geographical spread of migrant worker communities in South Somerset. The aim of the project was to identify language needs and the range of information that migrant workers would find useful in their own languages to help them to settle in South Somerset. Research uncovered many migrant workers in more isolated rural areas within the District as well as urban centres. The research led to a Somerset Countywide Welcome Pack in a variety of languages (a comprehensive on-line resource), funded by the Local Strategic Partnership (South Somerset Together). (Ref. 9F.13).

9F.4.2 Further mapping work was undertaken by **Somerset County Council** (Ref. 9F.14) on particular localities and industry sectors as follows:

- Chard: Portuguese workers in food preparation and production.
- Frome: Polish workers.
- Burnham-on-Sea/Highbridge and Minehead: in tourism and care sectors.
- Yeovil: NHS.
- Wiveliscombe: pig farming.
- Taunton: care sector.
- Fruit farms and the transportation industry.

9F.4.3 **Taunton Deane Local Strategic Partnership** also conducted a study of migrant workers, employers and providers in order to gain a better understanding of the needs of migrant workers and their families. (Ref. 9F.15) The research explored both language and other possible needs so that service areas can work to meet these. Methods used included telephone interviews with employers, informal questioning of representatives from local and regional groups and government employment organisations, questioning of local English for Speakers of Other Languages (ESOL) providers, and focus groups with ESOL learners.

9F.4.4 The study identified the need for a more co-ordinated response to the majority of employers who would like information leaflets on ESOL, Literacy, Numeracy, and IT provision and the need for ‘Welcome’ or ‘Information’ packs for migrant workers, including information on: opening bank accounts, National Insurance numbers, locations of community services, help with accommodation, local transport and taxis, and cultural information.

9F.4.5 The **South West Regional Development Agency** (RDA) commissioned a Scrutiny Review (Ref. 9F.16) in 2007 to gain a greater understanding of the scale and nature of migrant working in the region and the impact on business and the economy. The study revealed that between 2003 and 2005 hard to fill vacancies in the South West fell by 44 per cent, partly because of the increased use of migrant labour. Skill shortage vacancies also fell by 14 per cent over the same period, leading to an increase in business productivity. The sectors in which there was a greatest reliance on migrant labour were identified as agriculture, hospitality, food processing and care.

9F.4.6 It was difficult to identify where migrant workers were living or to build up a picture of concentration. Low absolute numbers, dispersal and 'invisibility' were highlighted as posing particular issues for service provision. Authorities in Cornwall and Dorset had experienced some issues concerning caravan sites in relation to overcrowding or unauthorised caravans, but elsewhere this did not appear to have been an issue. Only four councils were able to identify towns with relatively high numbers of houses in multiple occupation, including Taunton, Wellington, Torridge, Exmouth, Park District, Weymouth, Penzance and Hayle. One council noted that 'Available staff resource is insufficient for the Council to be confident that all licensable HMOs have been identified'.

9F.4.7 **The top five issues facing migrants** were identified as housing, exploitation, English language needs, information, advice and guidance (IAG) and racial tensions:

a) Housing

9F.4.8 The high price of accommodation and unscrupulous landlords and houses in multiple occupancy featured as the main issue. The requirement of a large deposit up front in the private sector means that multiple occupancy is the only way in which the deposit can be found. When houses in multiple occupation are closed down, there are often re-housing issues which can be difficult to meet. Limited entitlement to benefits means that those who are not able to find work or lose their jobs unexpectedly can then become homeless. Several respondents highlighted housing as an area where new pressures would be felt as workers bring their families over and begin to look for different sorts of accommodation.

b) Exploitation:

9F.4.9 Despite the establishment of the Gangmasters Licensing Authority (GLA), migrant workers are still being exploited and examples were given of workers being tied into employer accommodation; housed in sub-standard accommodation; having money deducted from their wages for housing, union fees, registration, transport etc; working for wages below the legal minimum; and being injured through unsafe working practices. The rural nature of large parts of the region means that it is easier for unscrupulous employers to remain undetected because of their geographic isolation.

c) English language needs:

9F.4.10 The study pointed out that a key protection against exploitation is English language development, yet the study found huge unmet needs for English courses and real issues around courses being delivered at the wrong time, wrong place and wrong level. The research carried out in Taunton Deane showed a need for 'short, sharp' classes in English as well as ESOL.

d) Information, advice and guidance:

9F.4.11 This is still a key area, despite a number of innovative initiatives across the region. As more dependants arrive, migrant workers' support needs are changing, with advice sought for families, housing, children, integration into school and pre-school. Welcome packs have proved useful, but can quickly become outdated.

e) **Racial tensions:**

9F.4.12 The study concluded that the above issues can become self-perpetuating with a lack of English language leaving new arrivals vulnerable to exploitation from employers and landlords, and unable to readily understand English laws. In turn, this can give rise to complaints about recycling; driving offences; over-crowding etc. so that migrant workers come to the attention of the local community through 'issues'. Language is not needed just for economic integration but also for social integration and community cohesion. The study found that hate crimes were on the increase as were assaults on people perceived to be Eastern European.

9F.4.13 The **South West Regional Assembly Scrutiny and Review Panel** undertook a wide ranging review involving several agencies in 2009 on the impact of migration. (Ref. 9F.17) They found that Worker Registration Scheme (WRS) registrations in the South West postal region fell by 47 per cent from 3,760 between July and September 2008 to 2,040 between October and December 2008. The recession and the decline in the value of the pound were cited as the reason for this. Migration from Bulgaria and Romania has continued to increase in 2006/07 and 2007/08, although this remains small in comparison to other nationalities (particularly Poles, but also Slovaks, Czechs, Hungarians and several non-EEA communities). The most recent national data suggests that A2 migration may also be beginning to fall. In a piece of research conducted by Equality South West to inform the Review, 27% of the businesses sampled felt that a substantial decline in migrant workers could result in them going out of business.

9F.4.14 The review found that the **skills** of migrant workers in the region are often not fully utilised by **employers**. Many migrant workers in occupations regarded as 'low skilled' have experience and/or qualifications commensurate with 'higher skilled' jobs. However, issues such as lack of English language skills and difficulty getting qualifications recognised and understood may prevent many migrant workers from taking up some positions. Research conducted by Equality South West found that while over 50 per cent of the migrant workers they surveyed had professional qualifications only a minority were using these in their current job. It was however noted that some migrant workers come to the UK with the specific intention of improving their English, and are content to work in relatively low skilled jobs whilst they do so, despite being essentially 'overqualified'. Equality South West research revealed that having more opportunities to learn English, and access to jobs of an appropriate level, are important factors in encouraging migrant workers to remain with them. However, some employers are understandably reluctant to invest in training for migrant workers, because they may only remain in the region for a relatively short length of time. It was noted that 'high skilled' sectors of the South West economy like nuclear, that rely on Science, Technology, English and Maths (STEM) skills also need to employ migrant workers.

9F.4.15 The review found that, in some areas, migration has contributed to significant **community tension** including public perceptions that migrant workers are 'taking our jobs' and being given preferential access to housing and other benefits. The media was identified as posing a significant challenge to community cohesion by perpetuating myths and stereotypes. Local agencies in the region were urged to work collectively to challenge negative or inaccurate reporting, and to identify and promote case studies to exemplify the positive contribution that migrant workers are making to the region's economy and communities. The Cornwall Migrant Worker

Group is developing a multi-agency 'media strategy' to help to dispel stereotypes and directly address negative media coverage. The Group are trialling engagement strategies, like carrying out regular briefings for local editors and broadcasting station managers to develop positive working relationships and encourage balanced and accurate coverage of migration issues. A similar approach was advocated at a regional level and it was stressed that migrant workers should not be viewed in isolation but integrated into mainstream service provision.

9F.4.16 The review made 22 recommendations to promote a more strategic and co-ordinated approach around migrants, including a review of the emerging Action Plan by the Forum for Migrant Workers which includes over 50 representatives from 37 organisations across the region.

9F.4.17 The **South West Regional Development Agency** (RDA) commissioned a study by the Equality South West (ESW) Migrant Workers Project (Ref. 9F.18) from May 2008 to March 2010 focused on the impact of migration on **business, employment and skills**. The findings were fed into the Scrutiny Review described above.

9F.4.18 The study found that while inflows of migrant workers to the South West have declined over the last 2-3 years, and a significant number of A8 nationals have gone home, there are increasing signs of migrant workers settling in the region (44% of respondents said that they did not know when they would return to their country of origin). The number of pupils with English as an additional language has risen from 11,600 in 2004 to 22,690 in 2009. According to DWP figures the number of migrant workers entering the region peaked in 2006/07 at just over 41,000, but since then it has declined to under 24,000 in 2009/10. Entrants in 2009/10 came from Poland (c.4,200); Latvia (c.1000) and Lithuania (c.900). Significant numbers of migrants also come from non-European Union countries, particularly China, India and the Philippines. Due to the growth of immigration restrictions most of these migrants work in more highly skilled areas of the economy.

9F.4.19 ESW uncovered a range of good practice case studies of employers offering English classes in the workplace and also encouraging migrants to move from entry level to specialist positions e.g. Delta Form, a packaging company based in Bridgewater, who ensure that all relevant skills and experience are captured on migrants' application forms. One company even laid on Polish taster courses for other workers to support the integration of Polish workers and improve relations.

9F.4.20 The studies described above have led to the development of a multi-agency **Migrant Workers Action Plan** (Ref. 9F.19) covering four themes:

a) Regional and Local Structures:

9F.4.21 Ensuring there are appropriate decision making structures at both regional and local level. Migration is an issue which transcends a number of different policy areas, including the economy, employment, community cohesion, health, education, housing and social inclusion. As such no single agency has responsibility for all the issues affecting migrant workers so a partnership approach is required. This section sets out a number of actions to ensure effective working between agencies.

b) Economy, Skills and Employer Engagement:

9F.4.22 Migration is of crucial benefit to the region's economy. Overall the Government has estimated that migrants contributed between 8.1% and 10% of regional Gross Value Added in the South West in 2008, of which between 2.0% and 2.4% was from migrants who arrived in the region after 2004. While the benefits of migration have been substantial there is a sense that the region is not taking advantage of the full economic potential that migrants bring. This section sets out a number of actions to support skills development and employer needs.

c) Supporting Migrant Workers:

9F.4.23 Many migrants are among the most vulnerable workers in the region's labour force. Lack of health and safety advice, poor accommodation provision, bonded labour, and illegal deductions from and sometimes non-payment of wages are among some of the conditions which many migrants meet when they come to the region. In contrast many other employers in the region support their migrant workforce, offering English language training and advice on living in the UK. It is important to ensure that on the one hand migrants are made aware of their employment rights and that enforcement agencies are given appropriate support to shut down bad employers, and on the other that those incidences of employer good practice are promoted and taken up by more employers. The public's perception of migrant workers varies considerably and is often informed by myths that migrants are 'stealing jobs' (when they primarily fill hard to fill vacancies) and are 'draining the public purse' (when they are actually net contributors). Consequently there is a need to promote positive images of migrant workers and explain to the wider public the benefits of migration. This section sets out a number of priorities and actions designed to support migrant workers directly and promote their integration into the wider community.

d) Responsive Public and Voluntary Services:

9F.4.24 As direct (and invariably net) contributors to public finances, migrant workers should be able to access all the public services they are legally entitled to in the same way that established communities can. However migrants coming into the region are often unaware of the most appropriate places to go in order to obtain services. In some cases this can create community tensions and produce a strain on public services, for example, when some migrants go to A&E services when it would be more appropriate to visit a GP. The need to provide appropriate multi-lingual advice (where migrants have not been able to gain fluency in English yet) on what is available is a major challenge for service providers. Another major issue, relevant for migrants working unconventional hours, will be appropriate information on out of hours' services. Education provision is of vital importance to community cohesion with access to suitable means of interpretation a critical issue for many schools in the region. This section sets out priorities for service providers in responding to migrants' needs.

9F.5 Implications for Hinkley Point C

9F.5.1 Technical Note 1 suggests that, at peak, HPC will require around 3,700 non-home-based workers, that is people who will move to primarily Somerset temporarily to work on the development. Technical Note 2 suggests around 90% will be male, and 85% will be single person households. Reflecting the wider construction industry a proportion of the workforce are likely to be foreign nationals, although it is not possible to accurately predict how many.

9F.5.2 The evidence review described above is mainly qualitative, identifying a broad range of issues which have been raised by a (international) migrant workforce. It is therefore not possible to make a quantitative assessment of what the impacts of the HPC workforce might be. However we can identify the types of things which could arise and plan to avoid any negative effects. Some of these issues are relevant to a non-home-based workforce regardless of nationality, whilst others, in relation to language issues for example, could arise from the specific needs of foreign nationals.

9F.5.3 For the first category, covering all non-home-based workers, the key issues are:

- ***The need for the provision of information*** e.g. Welcome Packs, and on-going information, advice and guidance for workers (Accommodation Management Strategy).
- ***Housing***: The need to signpost access to housing for workers, and to manage impacts, particularly on houses in multiple occupation (Accommodation Strategy/Fund).
- ***Employment and Jobs Training***: Ensuring that current residents feel they have equal access to employment opportunities, through positive projects to provide outreach and support employment training; (Construction Workforce Development Strategy).
- ***Access to Services***: Ensuring that non-home-based workers have access to necessary public services, whilst at the same time ensuring that existing residents feel they have equal access to provision. (EDF Energy contributing towards Education, Health, Leisure and the Community Fund).
- ***Addressing Potential Community Tension***; ensuring that a pre-dominantly male non-home-based workforce behaves well in the area, preventing tensions building up through other actions (e.g. local employment training and access to services) and ensuring that the police and other services have the resources to deal with any specific problems should they arise. (Accommodation Management Strategy, Worker Code of Conduct, Strategic Relationship Protocols and CSMP and through Campus and Leisure Management/Liaison).

GLOSSARY / ABBREVIATIONS

An explanation of the specific acoustic terminology referred to within this report is provided below.

dB	Sound levels from any source can be measured in frequency bands in order to provide detailed information about the spectral content of the noise i.e. whether is it high pitched, low pitched or with no distinct tonal character. These measurements are usually undertaken in octave or 1/3 octave frequency bands. If these values are logarithmically summed a single dB figure is obtained. This is usually not very helpful as it simply describes the total amount of acoustic energy measured and does not take any account of the ear's ability to hear certain frequencies more readily than others.
dBL_A	The dBL_A figure is used to relate better to the loudness of the sound heard. The dBL_A figure is obtained by subtracting an appropriate correction, which represents the variation in the ear's ability to hear different frequencies, from the individual octave or 1/3 octave band values, before logarithmically summing them. As a result, the single dBL_A value provides a good representation of how loud a sound is.
L_{Aeq}	As almost all sounds vary or fluctuate with time it is helpful, instead of having an instantaneous value to describe the noise event, to have an average of the total acoustic energy experienced over its duration. The L_{Aeq}, 07:00-19:00 for example, describes the equivalent continuous noise level over the 12 hour period between 7am and 7pm.
L_{Amax}	The L_{Amax} is the loudest instantaneous noise level. This is usually the loudest 125 milliseconds measured during any given period of time.
L_{An}	Another method of describing with a single value a noise level which varies over a given time period, is to consider the average amount of acoustic energy and the length of time for which a particular noise level is exceeded. If a level of x dB(A) is exceed for say 6 minutes within one hour, that level can be described as being exceeded for 10% of the measurement period. This is denoted as the $L_{A10,1hr}$ = x dB. The L_{A10} index is often used to describe road traffic noise whilst the L_{A90}, the noise level exceeded for 90% of the time, is the usual descriptor of the underlying background noise. L_{A1} in addition to L_{Amax} are common descriptors of construction noise.

EXECUTIVE SUMMARY

Electricité de France (EDF) proposes to construct and operate a new nuclear power station west of the existing Hinkley Point A (being decommissioned) and B facilities. The new station will comprise two new UK EPR type reactors and ancillary buildings.

This report details a baseline noise monitoring survey, undertaken between 27th April and 7th May 2009, as part of the Environmental Impact Assessment required for this development.

Measurements of ambient noise levels were undertaken at 10 locations to enable the assessment of potential impacts associated with both the construction and operation phases of the development.

Typical dominant noise sources identified during the survey included local road traffic, birdsong and surf movement (at a coastal monitoring location). The determined ambient noise levels were typical of a rural environment, dropping very low during the night time, and wind noise masking having an observable effect.

Operation of the Hinkley Point B power station was not typically observed, although a single significant short-term noisy event (venting) was recorded the Hinkley Point Visitors centre. Given the magnitude of the measured noise level, it is possible that this event would have been heard at neighbouring receptor locations.

1.0 INTRODUCTION

To assess properly the environmental noise impacts of the construction and operational phases of the Hinkley Point C development, it is essential that the existing ambient noise levels at the most noise sensitive locations are established prior to the commencement of the construction works.

A baseline noise survey was therefore undertaken by AMEC consultants between 27th April and 7th May 2009. All AMEC personnel involved in the monitoring programme have attained the UK Institute of Acoustics Certificate of Competence in Environmental Noise Measurements.

The scope and methodology of the survey was agreed in advance with relevant representatives from West Somerset (WSC) and Sedgemoor District (SDC) Councils. Noise monitoring locations were agreed in principle only, prior to discussions with property owners and/or residents.

This report is a factual document containing the results of the baseline noise measurements undertaken in the vicinity of the Hinkley Point site. There is no discussion regarding the implications of the results on the acoustic design of the buildings, this will be provided in a subsequent technical report that will be the basis of the EIA chapter.

The following sections of this report describe the measurement work undertaken and give a summary of the results. A glossary of acoustic terminology is provided above and the raw broadband monitoring data is provided in Appendix C.

1.1 Planning policy and guidance

The key regulations that relate to this study are set out below:

- Planning Policy Guidance 24: Planning and Noise (PPG 24).
- British Standard (BS) 7445: Parts 1-3: 1991/2003 – Description and measurement of environmental noise.

2.0 SITE DESCRIPTION

2.1 Site location and context

The Site is located on the north Somerset coast, east of Minehead and north of Bridgwater. Between 10 km and 20 km from the Site are the settlements of Williton, Watchet, Burnham-on-Sea, Bridgwater and Taunton and there are a number of smaller villages closer to the Site.

The Site is bounded to the north by the Bristol Channel (Bridgwater Bay) and to the south and west by agricultural fields. Land to the east is occupied by two nuclear power stations, Hinkley A and Hinkley B, which form the existing Hinkley Point power station complex. Hinkley A operated between 1965 and 2000 and is currently undergoing decommissioning. The station is now fully defueled and is being prepared for a period of aftercare and maintenance. Full site clearance is planned for 2095.

Hinkley B has operated since 1976. It is currently producing 70% of its maximum potential output of 860 MW and is scheduled to continue operating until at least 2016. Decommissioning will commence once operations have ceased.

2.2 Summary of proposed development

Electricité de France (EDF) plans to construct and operate a new nuclear power station at Hinkley Point ("Hinkley Point C) on the north Somerset coast. The site EDF has selected for the proposed development (the 'Site') is situated adjacent to the existing Hinkley A nuclear power station which is currently being decommissioned.

The principal component of the proposed power station will comprise two UK European Pressurised Reactors (UK EPRs), nominally unit C1 and C2. Each unit will have a net electrical output of up to 1630MW for export to the electricity grid.

In addition to the two UK EPRs, a range of ancillary buildings, related infrastructure and waste storage facilities will be required. In order to facilitate construction of this development, construction of a marine off-loading facility adjacent to the Site and extension to the existing sea defences may be required.

A summary of the key elements of each phase with respect to potential noise impacts on nearby receptor locations is provided below so that appropriateness of monitoring location selection is apparent.

2.2.1 Primary noise-generating activities during the construction phase

The primary noise and vibration sources during the development construction phase are those typical of an industrial construction site. Potential impacts will vary through the following major stages of the development:

- Mobilisation

- Upgrading work at Combwich Wharf
- Offloading operations at Combwich Wharf
- Earthworks and site platform construction
- Building construction
- EPR commissioning

Throughout these stages, the volume of construction traffic on local roads will vary considerably, with the potential to affect noise sensitive receptors along the main road network connecting the Site with the M5 motorway to the east.

2.2.2 Primary noise-generating activities during the operation phase

The primary noise sources of an operational EPR Unit include the following:

- The discharge stack
- Air entry and exit openings
- Ventilation openings
- Pumping stations
- Steam pipes
- Machine rooms

In addition to site plant noise, operation of the UK EPRs will generate road traffic, primarily for the transportation of the site workforce. Occasional heavy vehicular traffic will be generated for materials delivery during periods of heavy maintenance work.

2.2.3 Nearest noise sensitive receptors

Description of the nearest noise sensitive receptors to the proposed development will be provided. A table will be presented which identifies the locations of the receptors and their distances from site.

The nearest receptor locations to the Site comprise residential dwellings in the villages of Burton, Shurton and Wick to the south. Baseline noise survey locations that are representative of these locations have therefore been selected, as well as locations on the northern and southern site boundaries.

Construction and operation of the development also has the potential to impact on noise sensitive operational activities (e.g. office spaces) at the Hinkley B site immediately to the east of the Site.

Noise generated by construction and operation road traffic on the main road network will have the potential to impact on noise sensitive receptors aligning the likely transportation route corridor. Baseline monitoring has been undertaken at two locations representative of dwellings that are likely to experience the most significant impacts.

The baseline noise monitoring locations, are described in Table 1 see Appendix A for full description and plans.

Table 1 Baseline noise monitoring locations

Ref.	**Location**	**Representative of**	**Grid Ref.**	**Approximate distance (m)**	
				from the boundary of the SSA boundary	**from the nearest proposed EPR Unit**

3.0 SURVEY METHODOLOGY

3.1 Measurement methodology

The scope and methodology of the monitoring survey was agreed in advance with relevant representatives from West Somerset (WSC) and Sedgemoor District (SDC) Councils. Noise monitoring locations were agreed in principle only, prior to discussions with property owners and/or residents, and assessment of appropriate siting conditions at each location.

3.1.1 Planning Policy Guidance 24 'Planning and Noise' (PPG 24)

PPG 24 was introduced by the Department of the Environment in 1994. Paragraph 1 on page 1 of PPG 24 indicates that it was issued to:

> *'…provide advice on how the planning system can be used to minimise the adverse impact of noise without placing unreasonable restrictions on development or adding unduly to the costs and administrative burdens of business … It outlines some of the main considerations which local planning authorities should take into account in drawing up development plan policies and when determining planning applications for development which will either generate noise or be exposed to existing noise sources'*

For new developments that will introduce noise into an area PPG 24 confirms, in Annex 3, that it is appropriate to continue using previously established assessment routines, for example when assessing 'Noise from road traffic' (Annex 3, paragraph 1), 'Noise from industrial and commercial developments' (Annex 3, paragraphs 19-20) and 'Noise from construction sites' (Annex 3, paragraph 21). The appropriate assessment routines applicable to this development are discussed in the following sections.

3.1.2 BS 7445:2003 Part 1 'Description and measurement of environmental noise – Guide to quantities and procedures'

BS 7445-1:2003 defines the verification and traceability of instrumentation and noise measurement, as well as describing the basic procedures for the determination of environmental noise levels.

BS 7445-1 defines the following criteria for selection of appropriate noise level measurement locations:

- Microphone position either:
    - at least 3.5 m from any reflecting surface (other than the ground), i.e. in 'free-field' and 1.2 – 1.5 m above the ground (acknowledgement is made to other standards with specific heights); or,

  - 1 – 2 m from the façade of a receptor building, and 1.2 – 1.5 m above each floor level of interest.

- Minimise interference due to meteorological conditions by either:
  - measurement over a range of meteorological conditions to determine the long-term average sound level; or,
  - measurement under carefully specified meteorological conditions (i.e. conditions that would result in the most stable sound propagation)

BS 7445-1 also describes procedures for equipment calibration, which is described in Section 3.4, Quality Control Procedures.

3.1.3 Calculation of Road Traffic Noise (CRTN)

Paragraphs 43 and 44 of CRTN describes its Shortened Measurement Procedure for determining $L_{10(18\text{-hour})}$ road traffic noise levels. This involves the continuous measurement of traffic noise over any three consecutive hours between 10:00 and 17:00. This generates the $L_{10(3\text{-hour})}$ which is the arithmetic average of the three $L_{10,1\text{hour}}$ levels measured. Subtraction of 1 dB from the $L_{10(3\text{-hour})}$ gives the estimated $L_{10(18\text{-hour})}$ value.

CRTN stipulates that the following physical conditions should prevail for suitable measurement:

- Dry road surface;
- Appropriate wind conditions:
  - Prevalence of wind in the direction from the road to the microphone;
  - Average wind speed no more than 2 m/s from the road to the microphone;
  - Wind speed should not exceed 10 m/s in any direction (wind shield to be used)

CRTN stipulates that the monitoring location should have a substantially unobstructed (angle of view greater than 160°) view of the road, at a distance of 4 – 15 m from the near side carriageway edge.

The microphone should be positioned at 1.2 m above the road surface with the diaphragm horizontal, and in 'free-field' conditions, where possible.

3.1.4 BS 4142: 1997 'Method for rating noise affecting mixed residential and industrial areas'

BS 4142: 1997 details a method of rating the acceptability of increases in the background noise level L_{A90} at noise-sensitive developments affected by noise from proposed fixed developments.

The ambient background noise varies throughout the day and night-time periods. For new plant that may operate on a 24-hour basis, it is appropriate to measure the reasonable minimum ambient background noise level (which would normally occur in the early hours of the morning) at nearest noise-sensitive developments (normally local residential properties) and to use this value for comparison against the predicted rating noise level from the new plant.

BS4142 stipulates that measurement locations should be representative of outside locations *"at buildings where people are likely to be affected"*. Measurements should be undertaken in 'free-field' (at least 3.5 m from any reflecting surface other than the ground), ideally at a height of 1.2 – 1.5 m above the ground. If first floor (or higher) measurements are to be undertaken, the microphone should be located 1 m from the building façade.

In order to minimise the influences of external interference, noise measurements should not be undertaken:

- during excessive wind speeds (a wind shield should be used, BS4241 states that a wind shield is likely to be effective up to wind speeds of 5 m/s);
- during periods of heavy rainfall; and,
- close to high voltage power lines or radio transmitters

BS4142 stipulates two distinct reference time intervals to be assessed:

- 1 hour during the day
- 5 minutes during the night

The document does not define day and night, only expressing that night should refer to the period "when the general adult population are preparing for sleep or are actually sleeping". PPG 24, which recommends the use of BS4142, defines day and night-time periods as 07:00 – 23:00 and 23:00 – 07:00, respectively.

3.2 Monitoring period, duration and frequency

A combination of short-term attended and medium-term unattended measurements were undertaken. A summary of the monitoring regime and details of the microphone position, as well as a commentary of the significant noise sources at each location, is provided below:

3.2.1 ML1 Northern SSA boundary

The monitoring location was next to the coastal path, approximately 40 m south of the cliff edge. For all measurements, the sound level meter was positioned 1.5m above ground level, in free-field conditions.

For health and safety purposes, attended measurements were not undertaken during periods of darkness. The sound level meter was therefore deployed unattended overnight at this location.

The main daytime noise sources at this location include birdsong and surf. The movement of foliage in the wind also contributed to the ambient noise levels. Although not observed during the measurement period, intermittent noisy events are also likely to occur at this location, including: farming activities and nuclear plant operations (such as gas venting).

3.2.2 ML2 Knighton Farm

The monitoring location was approximately 30 m north of the nearest residential farm building, at Knighton Farm. For all measurements, the microphone was positioned 1.5 m above ground level, in free-field conditions.

Continuous monitoring was undertaken between Monday 27th and Thursday 30th April 2009.

During the measurement period, the main daytime noise sources at this location were mobile farming equipment and birdsong. The movement of foliage in the wind also contributed to the ambient noise levels. During the night-time, very low background noise levels, as low as 20 dB $L_{A90,15min}$, were recorded.

3.2.3 ML3 Doggetts

The monitoring location was approximately 7 m from the western façade of the residential dwelling ‘Doggetts’. For all measurements, the microphone was positioned 1.5 m above ground level, in free-field conditions.

Continuous monitoring was undertaken between Monday 27th and Tuesday 28th April 2009, and again between Thursday 30th April and Tuesday 5th May 2009. It was observed that, during the bank holiday week-end the resident had erected a decking platform approximately 5 m from the measurement position. Noise generated during this construction work (electric drill, screwdriver, hammering) is likely to have adversely affected measurements during the afternoon periods of the 2nd and 3rd May.

The main noise sources at this location during typical periods include the movement of foliage in the wind and birdsong. Distant road traffic on the A39 was also observed during the survey visit.

3.2.4 ML4 Wick House

The monitoring location was approximately 35 m northeast of the nearest residential dwelling at Wick House, and approximately 95 m south east of Wick Farm. For all measurements, the microphone was positioned 1.5 m above ground level, in free-field conditions.

Continuous monitoring was undertaken between Thursday 30th April and Sunday 3rd May 2009. Higher noise levels were recorded during the afternoon period of Saturday 2nd May which is likely to be due to children playing near to the sound level meter, notably using a trampoline which had been positioned approximately 12 m away.

The main noise sources at this location during typical periods include the movement of foliage in the wind; birdsong; and road traffic on the A39.

3.2.5 ML5 Southern SSA boundary

The monitoring location was close to a field border hedgerow, in any area of open, undulating countryside, approximately 180 m north of the nearest residential receptor location (Bishops Farm House). For all measurements, the microphone was positioned 1.5 m above ground level, in free-field conditions.

Short-term attended measurements were undertaken during the afternoon of the 28th April, and the morning of the 6th May 2009. Continuous unattended monitoring was undertaken during the evening and overnight between 6th and 7th May 2009.

The main noise sources at this location during typical periods include the movement of foliage in the wind and birdsong. Although not observed during the measurement period, intermittent noisy events associated with farming activities are also likely to occur at this location.

3.2.6 ML6 Hinkley Point Power Station (visitors centre)

The monitoring location was approximately 80 m north of the Hinkley Point power station Visitors Centre, at the northeast corner of the car park, approximately 160 m south of the coastline. For all measurements, the microphone was positioned 1.5 m above ground level, in free-field conditions.

Short-term measurements (two samples of 15-min duration) were undertaken during each of the daytime (07.00-17.00 hours), evening (17.00-23.00 hours) and night-time (23.00-07.00 hours) periods.

Continuous unattended monitoring was undertaken between Wednesday 6th and Thursday 7th May 2009. An operative cutting the grassland (using a strimmer) north of the measurement period on the afternoon of the 6th May contributed to the measured ambient noise levels. The background acoustic climate at this location was dominated by industrial noise from the Hinkley Point A and B sites, and therefore the L_{A90} did not drop below 45 dB throughout the monitoring period. Between the hours of 04:45 and 05:00 on the 7th May 2009, a significant event occurred, which generated a level of 86 dB $L_{Amax(fast)}$. Analysis of the 1/3rd octave spectral L_{max} data shows the noise emission contained significant high frequency sound (above 1 kHz). This, as well as analysis of the statistical data, indicates that the source was likely to be short-term gas venting at the existing Hinkley Point B site.

Other noise sources at this location include: surf, birdsong and occasional vehicle movements in the visitors centre car park.

3.2.7 ML7 Short-term attended monitoring (Rodway)

The monitoring location was 4 m east of the carriageway edge of Rodway road, north of Cannington, at the entrance to the Cannington community football pitch. This location was representative of residential dwellings in north Cannington, and between Cannington and Combwich.

The microphone was positioned 1.5 m above the road surface, in free-field conditions. At this location Rodway has a speed limit of 40 mph, with a good surface (dry during the measurement period) and there is a significant upward gradient from the south. The microphone position had a 180º view of the road, and there were no opposite reflections.

The existing Baseline Noise Level (BNL) was determined in accordance with the CRTN Shortened Measurement Procedure. An attended measurement was carried out over three consecutive daytime hours (13:00 – 16:00).

The daytime acoustic climate at this location was dominated by road traffic on Rodway. Other, less significant noise sources included birdsong and intermittent tractor-mower movements on the football pitch.

3.2.8 ML8 Short-term attended monitoring (Chad's Hill)

The monitoring location was 3 m east of the carriageway edge of Chad's Hill, 40 m north of its junction with Park Lane and Sandy Lane. This location was representative of residential dwellings on Park Lane, Sandy Lane and Chad's Hill.

The microphone was positioned 1.2 m above the road surface, in free-field conditions. At this location Chad's Hill has a speed limit of 30 mph, and is a reasonably level single lane track, used primarily for access to and from Castle Hill Quarry to the north, and by farm vehicles. The road surface was dry during the measurement period, and the microphone position had a 150º view of the road, with no opposite reflections.

The existing Baseline Noise Level (BNL) was determined in accordance with the CRTN Shortened Measurement Procedure. An attended measurement was carried out over three consecutive daytime hours (10:00 – 13:00). A vehicle count during the measurement period shows a significant number of HGVs (34%) which were primarily quarry trucks, and farm vehicles (10%), with cars and light vans making up the remainder.

Throughout the measurement survey, significant noise from Castle Hill Quarry was observed. Notable sources included an aggregate crusher plant (repetitive clunks) and quarry vehicle reversing bleepers.

Other noise sources identified during the survey included: birdsong; foliage moving in the wind; sheep bleating; and distant road traffic in Cannington.

3.2.9 ML9 Short-term attended monitoring (Combwich)

The monitoring location was approximately 22 m southeast of the nearest residential property on Riverside, Combwich, and approximately 43 m north of the existing Combwich Wharf facility. The microphone was positioned 1.2 m above ground level, in free-field conditions.

Short-term attended measurements were undertaken for a period of 1 hour during the morning of Wednesday 29th April 2009.

During the survey, noise sources that contributed to the acoustic climate at this location included birdsong, occasional vehicle movements on Riverside and in the car park at the BE laboratory to the south.

3.2.10 ML10 Short-term attended monitoring (Northbrook Road)

The monitoring location was approximately 10 m southwest of the nearest residential property on Northbrook Road, and 240 m northeast of the carriageway edge of the A39 roundabout, which is the dominant noise source in the area. This location was representative of residential dwellings on Northbrook Road, Lonsdale Road and Southbrook Close. The microphone was positioned 1.2 m above the road surface, in free-field conditions.

The existing Baseline Noise Level (BNL) for the A39 was determined in accordance with the CRTN Shortened Measurement Procedure. An attended measurement was carried out over three consecutive daytime hours (14:00 – 17:00). At this location the A39 has a speed limit of 40 mph, with a good surface (dry during the measurement period). The microphone position had a limited angle of view of the road (35º), and there were no opposite reflections.

Other noise sources identified at this location included birdsong and intermittent roofing work at a property 180 m to the south.

3.3 Equipment

Equipment used during this measurement survey included:

Rion NL-31	Class 1 Sound Level Meter	s/n 672900
Rion NA-28	Class 1 Sound Level Meter	s/n 00370312
Rion UC-53A	Microphone	s/n 312092
Rion UC-59	Microphone	s/n 00405
Rion NC-74	Class 1 Sound Level Calibrator	s/n 34712641

3.4 Quality control procedures

All AMEC personnel involved in the monitoring programme have attained the UK Institute of Acoustics Certificate of Competence in Environmental Noise Measurements.

All equipment specified in Section 3.3 above (sound level meters, microphones, preamplifiers and field calibrators) had been fully calibrated within the 12 months preceding the survey. Calibration certificates for all monitoring equipment used are provided in Appendix D.

As stipulated in BS7445-1: 2003, field calibrations were carried out in accordance with the manufacturer's specifications before and after each series of measurements. A class 1 field calibrator in accordance BS EN 60942: 2003 was used to set the sensitivity of the entire sound measurement system at the start of each series of measurements, or each medium-term monitoring period, and to check that no significant sensitivity drift had occurred upon completion.

3.5 Constraints and variations

Two additional noise monitoring locations were included that were not previously included in the Noise Monitoring Plan to account for changes to the emerging development construction programme and transportation options studies. These included a short-term measurement at the nearest residential receptor location to Combwich Wharf to enable an assessment of the potential upgrade and use of this facility. A further road traffic noise survey was included in Cannington to assess the potential impacts of a possible new bypass.

There were no other deviations from the Noise Monitoring Plan.

3.6 Meteorological conditions

A record was kept of the prevailing weather conditions during the monitoring period. A summary of observations as well as intermittent measurements of wind speed and ambient temperature is provided in Table 2.

In addition, meteorological data was recorded continuously at a temporary weather station on the Hinkley Point site (Grid Ref. 320790,145525). The output data for the entire baseline noise survey period from this site is summarised in Figures 1 and 2 below, and the full data is provided in Appendix E.

Despite occasional light rain, the overall meteorological conditions throughout the measurement period were conducive to obtaining suitable baseline monitoring data.

Table 2 Summary of meteorological conditions during the baseline noise survey

Date	Time	Ambient Temp. (°C)	Average Wind Speed (m/s)	Prevailing Wind Direction (from)	Observations
27/04/09	13:15	10	1 – 3	NW	Overcast, light rain
27/04/09	16:35	15	4 – 5	NW	3/8 cloud, dry
27/04/09	18:30*	14	4 – 5	NW	2/8 cloud, dry
27/04/09	20:00	11	4 – 5	NW	2/8 cloud, dry
28/04/09	08:00	13	1 – 2	NNW	4/8 cloud, dry
28/04/09	10:12	19	2 – 3	NNW	2/8 cloud, dry
28/04/09	11:00	22	< 1	NW	1/8 cloud, dry
28/04/09	14:00*	17	4 – 5	NNW	4/8 cloud, dry
28/04/09	15:00	14	1 – 2	NW	1/8 cloud, dry
29/04/09	08:25	19	< 1	W	1/8 cloud, dry
29/04/09	16:10	22	2 – 3	W	4/8 cloud, dry
30/04/09	10:00	19	2 – 4	SSW	Overcast, light rain
05/05/09	12:15	16	4 – 5	W	7/8 cloud, dry
05/05/09	14:00	17	1 – 2	NW	7/8 cloud, dry
06/05/09	08:45	12	1 – 2	NW	4/8 cloud, dry
06/05/09	12:00	18	1 – 2	NW	2/8 cloud, dry
06/05/09	14:00	20	< 1	W	1/8 cloud, dry
06/05/09	17:45*	15	4 – 5	NW	6/8 cloud, dry
07/05/09	09:45*	14	1 – 3	NW	6/8 cloud, dry

Note: * observations at ML1 (coast) where stronger winds persisted.

Figure 1 Measured wind speed and temperature data (27th April – 7th May 2009)

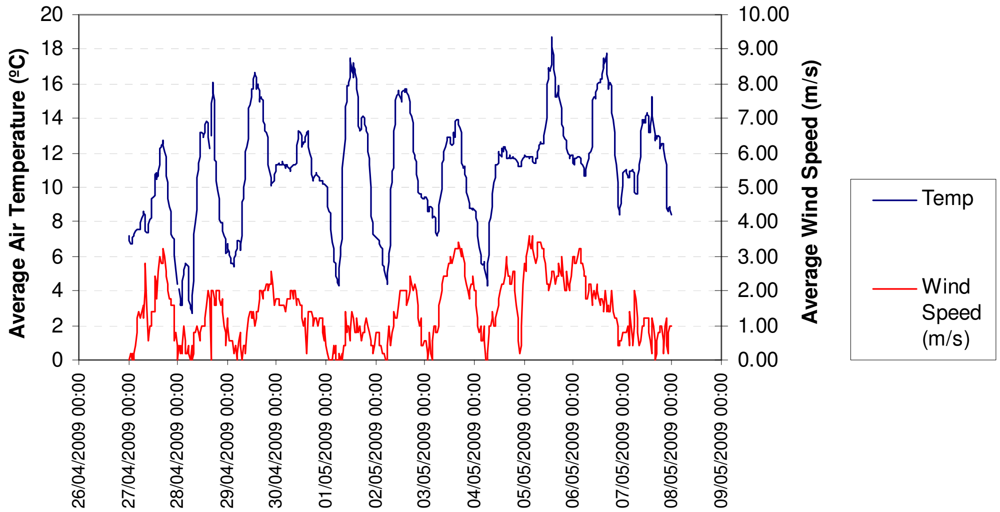

Figure 2 Measured rainfall data (27th April – 7th May 2009)

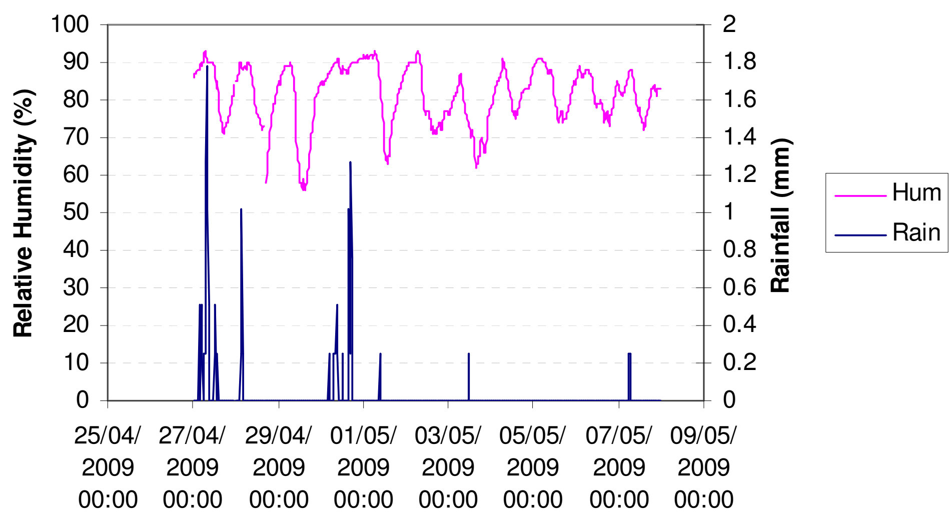

4.0 SUMMARY OF MEASUREMENT RESULTS

4.1 Monitoring data

A summary of the results of the baseline noise measurements are tabulated below. Full broadband datasets are provided in Appendix C. One third octave data was obtained at four monitoring locations (ML1, ML2, ML4 and ML6). This data will be used in the analysis of potential impacts, and presented in the technical assessment report where applicable.

For each monitoring period: 'Day' represents 07:00 – 23:00; 'Evening' represents 19:00 – 23:00; and, 'Night' represents 23:00 – 07:00.

Table 3 Monitoring location 1 – Northern SSA boundary

Monitoring Period (start date)	Start Time	Measurement Duration (T)	Sound Pressure Level, dB (fast time-weighting)			
			$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{A10,T}$ *	$L_{Amax,T}$
Day (29/04/09)	16:25	2 hour	44.7	36.0	48.0	60.6
Day (07/05/09)	07:00	3 hour	41.9	36.8	43.6	64.0
Evening (06/05/09)	19:00	4 hour	45.2	41.1	45.9	61.5
Night (06/05/09)	23:00	8 hour	46.5	41.6	46.0	64.5

Notes: All values are in dB re $2x10^{-5}$Pa, Free-field.

* L_{A90} and L_{A10} values are arithmetic averages of individual 15-minute measurements

Table 4 Monitoring location 2 – Knighton Farm

Monitoring Period (start date)	Start Time	Measurement Duration (T)	Sound Pressure Level, dB (fast time-weighting)			
			$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{A10,T}$ *	$L_{Amax,T}$
Day + (27/04/09)	14:15	8.75 hour	44.1	33.3	42.2	74.4
Evening (27/04/09)	19:00	4 hour	41.0	26.8	35.5	64.9
Night (27/04/09)	23:00	8 hour	45.7	31.0	39.1	77.0
Day (28/04/09)	07:00	16 hour	45.3	30.4	44.3	74.4
Evening (28/04/09)	19:00	4 hour	37.4	26.4	33.9	74.4
Night (28/04/09)	23:00	8 hour	42.7	26.1	34.2	69.9
Day (29/04/09)	07:00	16 hour	47.5	32.9	46.5	79.0
Evening (29/04/09)	19:00	4 hour	40.7	30.9	39.0	71.8
Night (29/04/09)	23:00	8 hour	42.8	26.3	36.8	77.5

Notes: All values are in dB re $2x10^{-5}$Pa, Free-field.

* L_{A90} and L_{A10} values are arithmetic averages of individual 15-minute measurements.

+ Incomplete daytime period.

Table 5 Monitoring location 3 – Doggetts

Monitoring Period (start date)	Start Time	Measurement Duration (T)	Sound Pressure Level, dB (fast time-weighting)			
			$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{A10,T}$ *	$L_{Amax,T}$
Day + (27/04/09)	14:15	8.75 hour	59.4	37.5	45.8	91.9
Evening (27/04/09)	19:00	4 hour	62.8	32.9	42.4	55.3
Night (27/04/09)	23:00	8 hour	43.2	36.1	42.1	62.1
Day + (28/04/09)	07:00	7.75 hour	44.6	33.9	44.5	75.0
Day + (30/04/09)	10:00	13 hour	40.2	32.3	40.4	70.5
Evening (30/04/09)	19:00	4 hour	34.5	29.8	36.2	49.2
Night (30/04/09)	23:00	8 hour	39.7	29.5	35.5	66.2

Appendix C. Raw monitoring data

Raw broadband monitoring data are provided in the following tables. One third octave monitoring data were also obtained at four locations (ML1, ML2, ML 4 and ML6); this data will be used in the analysis of potential impacts, and presented in the technical assessment report where applicable.

All sound pressure level data presented are expressed in dB re: 20 µPa. Start times are British Summer Time (BST).

Table C1.1 ML1 (29/04/09)

Start Time	15-minute Sound Pressure Level, dBA (fast), Free-field			
	L_{Aeq}	L_{A90}	L_{A10}	L_{Amax}
08:23	44.2	39.5	46.9	63
08:38	44.3	40	47	52.7
08:53	42.9	38.3	45.8	53.7

Appendix D. Calibration certificates

D1.1 Rion NL-31 (s/n 00672900)

Reviewed by
RC
16/12/2008.

Measurement Systems

CERTIFICATE OF CALIBRATION

Certificate Number CAL110802
Date of Issue 04/11/2008

Customer AMEC Earth & Environmental Ltd.

Description of Instrument

Sound Level Meter
Rion NL-31 Sound Level Analyser [Serial No. 00672900] with
Rion UC-53A Microphone [Serial No.312092] and
Rion NH-21 Preamplifier [Serial No.23077]
Fitted with a WS-10 foam windshield.

The instrument successfully completed the Class 1 Periodic Tests of BS EN 61672.

Associated Calibrator
Rion NC-74 [Serial No. 34973224] with ½" adaptor type NC-74-002 fitted. This calibrator was calibrated by ANV Measurement Systems on 04/11/08 [Certificate No.110801].

Date of Calibration 04/11/2008.

Test Procedure
ANV/CAL/SLM/002a
Calibration Results currently at Issue 3
Test procedures in accordance with BS EN 61672-3:2006.
NOTE: Test 10.1 (Self Generated Noise with Microphone Installed) omitted.

GLOSSARY / ABBREVIATIONS

An explanation of the specific acoustic terminology referred to within this report is provided below.

dB	Sound levels from any source can be measured in frequency bands in order to provide detailed information about the spectral content of the noise i.e. whether is it high pitched, low pitched or with no distinct tonal character. These measurements are usually undertaken in octave or 1/3 octave frequency bands. If these values are logarithmically summed a single dB figure is obtained. This is usually not very helpful as it simply describes the total amount of acoustic energy measured and does not take any account of the ear's ability to hear certain frequencies more readily than others.
dBL_A	The dBL_A figure is used to relate better to the loudness of the sound heard. The dBL_A figure is obtained by subtracting an appropriate correction, which represents the variation in the ear's ability to hear different frequencies, from the individual octave or 1/3 octave band values, before logarithmically summing them. As a result, the single dBL_A value provides a good representation of how loud a sound is.
L_{Aeq}	As almost all sounds vary or fluctuate with time it is helpful, instead of having an instantaneous value to describe the noise event, to have an average of the total acoustic energy experienced over its duration. The L_{Aeq}, 07:00-19:00 for example, describes the equivalent continuous noise level over the 12 hour period between 7am and 7pm.
L_{Amax}	The L_{Amax} is the loudest instantaneous noise level. This is usually the loudest 125 milliseconds measured during any given period of time.
L_{An}	Another method of describing with a single value a noise level which varies over a given time period, is to consider the average amount of acoustic energy and the length of time for which a particular noise level is exceeded. If a level of x dB(A) is exceed for say 6 minutes within one hour, that level can be described as being exceeded for 10% of the measurement period. This is denoted as the $L_{A10,1hr}$ = x dB. The L_{A10} index is often used to describe road traffic noise whilst the L_{A90}, the noise level exceeded for 90% of the time, is the usual descriptor of the underlying background noise. L_{A1} in addition to L_{Amax} are common descriptors of construction noise.
PPV	The Peak Particle Velocity is the maximum velocity which is recorded during a particular event and can refer to a particular orientation (vertical or horizontal) or to the maximum (units: mm/s).

EXECUTIVE SUMMARY

Electricité de France (EDF) proposes to construct and operate a new nuclear power station west of the existing Hinkley Point A (being decommissioned) and B facilities. The new station will comprise two UK EPR type reactors and ancillary buildings.

This report details a noise and vibration monitoring survey, undertaken between 20th and 29th April 2010, during earthworks blasting tests as part of the site investigative works. The monitoring regime enabled the determination of existing background noise and vibration levels, as well as measurement during blasting events.

Measurements of both environmental noise and vibration levels were undertaken at two locations, including: a residential property in Shurton and between the blasting site and Hinkley Point A.

The measurement results indicate that the vibration magnitude of blast events, although possibly perceptible to alerted residents, was determined to be Very Low in relation to nuisance impact criteria. Cosmetic damage to buildings is highly unlikely as threshold values for buildings are much higher than those for perception and disturbance used in this study.

The maximum noise levels generated by blasting events were very low and are not considered significant in terms of nuisance disturbance.

1.0 INTRODUCTION

As part of the earthworks programme for the construction the Hinkley Point C nuclear power station, blasting of the bedrock may be required. These operations have the potential to generate noise and vibration at the nearest sensitive receptors, including private residential dwellings in Shurton.

Testing of blasting operations has therefore been undertaken by EDF's earthworks contractors to determine how the underlying bedrock reacts to such events.

A noise and vibration survey was undertaken by AMEC consultants between 20th and 29th April 2010, allowing collection of baseline data as well as measurements during blasting events. All AMEC personnel involved in the monitoring programme have attained the UK Institute of Acoustics Certificate of Competence in Environmental Noise Measurements.

This report is a factual document containing the results of the continuous noise and vibration measurements undertaken at two locations simultaneously. Commentary is also provided regarding the potential for noise and/or vibration impacts based upon published disturbance criteria.

The following sections of this report describe the measurement work undertaken and give a summary of the results.

2.0 SITE DESCRIPTION

2.1 Site location and context

The Site is located on the north Somerset coast, east of Minehead and north of Bridgwater. Between 10 km and 20 km from the Site are the settlements of Williton, Watchet, Burnham-on-Sea, Bridgwater and Taunton and there are a number of smaller villages closer to the Site.

The Site is bounded to the north by the Bristol Channel (Bridgwater Bay) and to the south and west by agricultural fields. Land to the east is occupied by two nuclear power stations, Hinkley A and Hinkley B, which form the existing Hinkley Point power station complex. Hinkley A operated between 1965 and 2000 and is currently undergoing decommissioning. The station is now fully defueled and is being prepared for a period of aftercare and maintenance. Full site clearance is planned for 2095.

Hinkley B has operated since 1976. It is currently producing 70% of its maximum potential output of 860 MW and is scheduled to continue operating until at least 2016. Decommissioning will commence once operations have ceased.

2.2 Nearest noise and vibration sensitive receptors

The nearest receptor locations to the Site comprise residential dwellings in the villages of Burton, Shurton and Wick to the south. Baseline noise survey locations that are representative of these locations have therefore been selected, as well as locations on the northern and southern site boundaries.

Construction and operation of the development also has the potential to impact on noise sensitive operational activities (e.g. office spaces) at the Hinkley B site immediately to the east of the Site.

Noise generated by construction and operation road traffic on the main road network will have the potential to impact on noise sensitive receptors aligning the likely transportation route corridor. Baseline monitoring has been undertaken at two locations representative of dwellings that are likely to experience the highest magnitude of impact.

The baseline noise monitoring locations, are described in Table 1.

Table 1 Noise and vibration monitoring locations

Ref.	Location	Representative of	Grid Ref.	Approximate distance from trial blasting pits (m)
ML1	Bayleys Brook House	Residential dwellings in Shurton	320225, 144380	1,600
ML2	Knighton Farm (residential)	North of Hinkley Point B Training and Visitors Centre	320680, 146152	800

3.0 TRIAL BLAST EVENTS

Table 2 identifies the three trial blasts that were undertaken during the measurement period. Figure A.1 in Appendix A identifies the location of the trial blast pits in relation to the noise and vibration monitoring locations.

Table 2 Log of blast events

Date	Reference	Time	Maximum Instantaneous Charge (kg)	Description
22/04/10	B-BBH2	14:53	15	Depth 9.40 m below ground level with soft slurry in base
	B-BBH3	15:50	22.5	Depth 9.60 m below ground level with soft slurry in base
	B-BBH1	15:55	22	Depth 9.40 m below ground level with soft slurry in base

4.0 METHODOLOGY

4.1 Measurement methodology

The following guidance methodologies were adopted:

4.1.1 Noise

BS 7445:2003 Part 1 'Description and measurement of environmental noise – Guide to quantities and procedures'

BS 7445-1:2003 defines the verification and traceability of instrumentation and noise measurement, as well as describing the basic procedures for the determination of environmental noise levels.

BS 7445-1 defines the following criteria for selection of appropriate noise level measurement locations:

- Microphone position either:
    - at least 3.5 m from any reflecting surface (other than the ground), i.e. in 'free-field' and 1.2 – 1.5 m above the ground (acknowledgement is made to other standards with specific heights); or,
    - 1 – 2 m from the façade of a receptor building, and 1.2 – 1.5 m above each floor level of interest.
- Minimise interference due to meteorological conditions by either:
    - measurement over a range of meteorological conditions to determine the long-term average sound level; or,
    - measurement under carefully specified meteorological conditions (i.e. conditions that would result in the most stable sound propagation).

BS 7445-1 also describes procedures for equipment calibration, which are presented in Section 3.4, Quality Control Procedures.

4.1.2 Vibration

BS 6472:2008 Part 2 'Guide to evaluation of human exposure to vibration in buildings' - Blast-induced vibration'

BS 6472-2 recommends that measurement of vibration from blasting events should determine the Peak Particle Velocity (PPV), which is measured in mm/s. With respect to measurement location, BS 6472-2 states:

> *"…measurements should be made outside the building on a well-founded hard surface as close to the building as possible".*

4.2 Assessment criteria

4.2.1 Noise

Based on advice provided in Annex E of British Standard BS 5228: 2009 *'Noise and vibration control on construction and open sites' - Part 1 'Noise'*, the assessment criteria presented in Table 3 has been developed for earthworks associated with the construction of Hinkley Point C.

Table 3 Noise magnitude scale for preliminary works construction activities at Hinkley Point C

Assessment Period		**Construction Noise Magnitude dB $L_{Aeq,1hour}$ (free-field)**			
Day of Week	**Time of Day**	**Very Low**	**Low**	**Medium**	**High**
Monday – Friday	07.00 – 19.00	<45	45-55	55-65	>65
	19.00 – 23.00	<40	40-50	50-60	>60
	23.00 – 07:00	<35	35-40	40-45	>45
Saturday	07.00 – 19.00	<45	45-55	55-65	>65
	19.00 – 23.00	<40	40-50	50-60	>60
	23.00 – 07:00	<35	35-40	40-45	>45
Sunday and Bank Holidays	07.00 – 19.00	<40	40-50	50-60	>60
	19.00 – 23.00	<35	35-45	45-55	>55
	23.00 – 07:00	<35	35-40	40-45	>45

Notes: dB re: 20 μPa

4.2.2 Vibration

In terms of vibration perception, BS 5228-2 suggests that a level of 0.3 mm/s *"…might be just perceptible in residential environments"*. However, in terms of nuisance effects this relates to permanent continuous vibration sources, rather than infrequent blasting events as proposed.

BS 5228-2 provides useful discussion on the perception and effects of vibration on a community:

> *"Vibration nuisance is frequently associated with the assumption that, if vibrations can be felt, then damage is inevitable; however, considerably greater levels of vibration are required to cause damage to buildings and structures, or to cause computers and similar electronic equipment to malfunction. Vibrations transmitted from site activities to the neighbourhood can, therefore, cause anxiety as well as annoyance, and can disturb sleep, work or leisure activities. In*

any neighbourhood, some individuals will be more sensitive to vibration than others."

"…adverse community reaction is sometimes based upon concern over building damage, even when the vibration is just perceptible. It is therefore important to assure the community that vibration levels generally have to be of significant magnitude for even cosmetic damage to occur."

Table 1 of BS 6472-2 provides recommended maximum satisfactory magnitudes of vibration with respect to human response for up to three blast vibration events per day. These criteria, as measured at a residential receptor location, are presented in Table 4 below.

Table 4 Vibration magnitude assessment criteria (blasting operations)

Magnitude	Guidelines
High	Generation of PPV in excess of 24 mm/s
Medium	Generation of PPV in the range of >10 to <24mm/s
Low	Generation of PPV in the range of >6 to <10 mm/s
Very Low	Generation of PPV below 6 mm/s

In addition to the above, BS 6472-2 also recommends a limit of 2 mm/s for blast events occurring during the night-time period (23:00 – 07:00).

4.3 Monitoring period, duration and frequency

Long-term unattended measurements were undertaken at both monitoring locations. A summary of the monitoring regime and details of the microphone and seismograph positions, as well as a commentary of the significant noise sources at each location, is provided below.

4.3.1 ML1 Bayleys Brook House

The vibration transducer was positioned on a concrete surface connected to the northern extent of Bayleys Brook House residential property, approximately 1,600 m south of the trial blasting pits. A sandbag was placed over the transducer to hold it securely in place throughout the monitoring period.

The microphone was positioned approximately 3 m from the northern façade of Bayley Brook House at a height of 1.5 m above ground level.

Continuous monitoring was undertaken between Tuesday 20th and Thursday 29th April 2010.

The main daytime noise sources at this location include birdsong, surf, earthworks machinery operating to the south west and various industrial sources at Hinkley

Point A. Operation of Hinkley Point B is likely to have also contributed to the background noise levels, notably during the quieter night-time periods.

4.3.2 ML2 North of Hinkley Point B Training and Visitors Centre

The monitoring location was approximately 800 m east of the trial blasting pits, and approximately 30 m west of the Hinkley Point A boundary fence and access gate. A sandbag was placed over the transducer to hold it securely in place throughout the monitoring period.

The microphone was positioned at the same location but at a height of 1.5 m above ground level, in free-field conditions.

Continuous monitoring was undertaken between Tuesday 20th and Wednesday 28th April 2010.

The main daytime noise sources at this location include birdsong and residential activities such as gardening (lawn-mowing).

4.4 Equipment

Equipment used during this measurement survey included:

Rion NL-31	Class 1 Sound Level Meter	s/n 583274
Rion NA-31	Class 1 Sound Level Meter	s/n 773044
Vibrock V901	Seismograph	s/n 1449
Vibrock V901	Seismograph	s/n 896

4.5 Quality control procedures

All AMEC personnel involved in the monitoring programme have attained the UK Institute of Acoustics Certificate of Competence in Environmental Noise Measurements.

All equipment specified in Section 4.4 above (sound level meters, microphones, preamplifiers and field calibrators) had been fully calibrated within the 12 months preceding the survey. Calibration certificates for all monitoring equipment used are provided in Appendix D.

As stipulated in BS 7445-1: 2003, field calibrations (noise) were carried out in accordance with the manufacturer's specifications before and after each series of measurements. A class 1 field calibrator in accordance BS EN 60942: 2003 was used to set the sensitivity of the entire sound measurement system at the start of each series of measurements, or each medium-term monitoring period, and to check that no significant sensitivity drift had occurred upon completion.

4.6 Meteorological conditions

Throughout the monitoring period, the weather was generally dry and with above average temperatures for the time of year. On the day of the blasting tests (22/04/10): an easterly wind prevailed at a speed of 2-7 mph; the ambient temperature just exceeded the average maximum high (13˚C); and, there was no rainfall.

5.0 SUMMARY OF MEASUREMENT RESULTS

5.1 Monitoring data

A summary of the results of the noise and vibration measurements are presented in Tables 5 to 8. Graphs showing the variation in noise and maximum vibration levels are provided in Appendices B and C respectively.

For each monitoring period: 'Day' represents 07:00 – 23:00; 'Evening' represents 19:00 – 23:00; and, 'Night' represents 23:00 – 07:00.

Table 5 Summary of ambient noise levels – Bayleys Brook House (ML1)

Monitoring period (start date)	Measurement duration (T)	Sound Pressure Level, dB (fast time-weighting)		
		$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{Amax,T}$
Night (20/04/10)	8 hours	43.2	35.7	72.1
Day (21/04/10)	16 hours	53.8	37.5	93.7
Night (21/04/10)	8 hours	44.9	36.7	80.0
Day (22/04/10)	16 hours	45.9	37.1	80.0
Night (22/04/10)	8 hours	43.5	35.1	65.4
Day (23/04/10)	16 hours	46.5	35.3	86.9
Night (23/04/10)	8 hours	43.9	34.0	73.5
Day (24/04/10)	16 hours	63.8	36.1	103.9
Night (24/04/10)	8 hours	43.8	33.9	67.8
Day (25/04/10)	16 hours	48.2	37.1	83.5
Night (25/04/10)	8 hours	45.8	33.7	75.7
Day (26/04/10)	16 hours	46.1	37.6	78.9
Night (26/04/10)	8 hours	45.2	35.9	74.5
Day (27/04/10)	16 hours	49.9	36.4	80.5
Night (27/04/10)	8 hours	44.0	31.9	68.0
Day (28/04/10)	16 hours	45.1	36.5	74.7
Night (28/04/10)	8 hours	49.4	33.2	82.6

Notes: All values are in dB re 20 µPa, Free-field.

* L_{A90} values are arithmetic averages of individual 1-minute measurements

Table 6 Summary of ambient noise levels – North of Hinkley Point B Training and Visitors Centre (ML2)

Monitoring period (start date)	Measurement duration (T)	Sound Pressure Level, dB (fast time-weighting)		
		$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{Amax,T}$

6.0 DISCUSSION

Figures 1 - 4 show the measured noise and vibration levels recorded at the moment of each blast event at each measurement position.

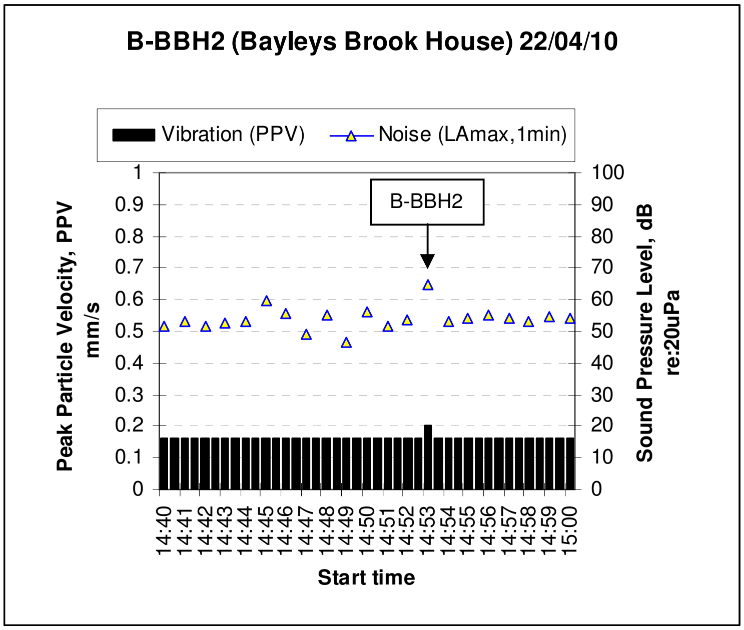

Figure 1 Measured noise and vibration levels at Bayleys Brook House during blast event B-BBH2

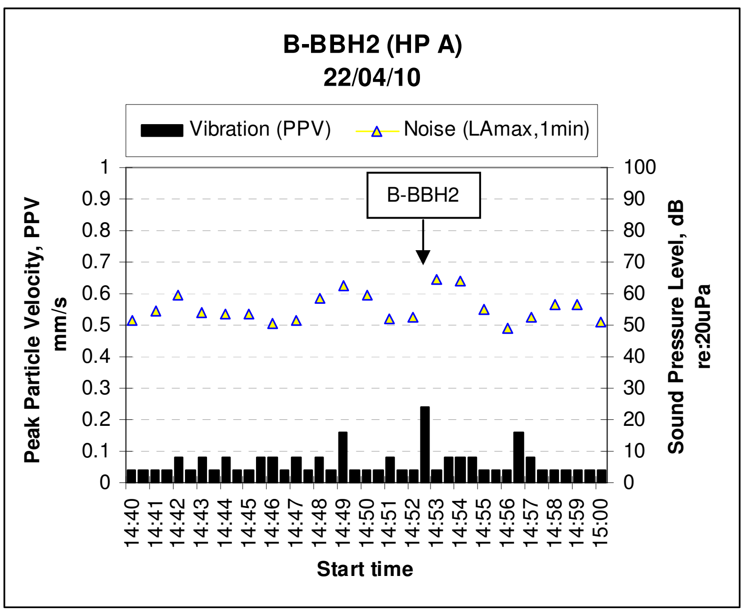

Figure 2 Measured noise and vibration levels at Hinkley Point A monitoring location during blast event B-BBH2

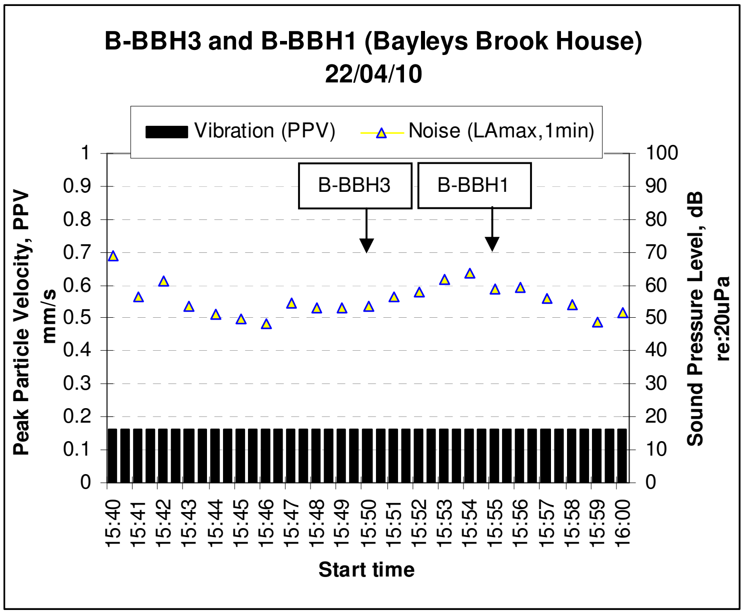

Figure 3 **Measured noise and vibration levels at Bayleys Brook House during blast events B-BBH3 and B-BBH1**

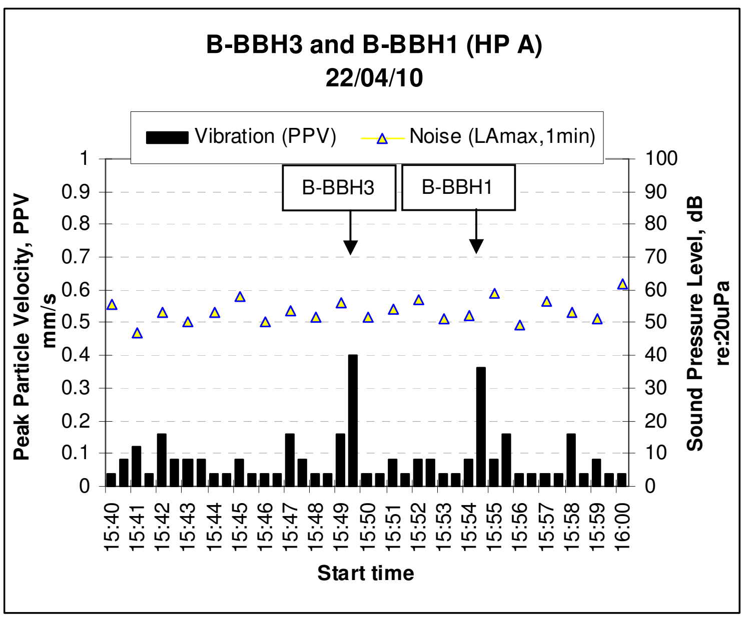

Figure 4 **Measured noise and vibration levels at Hinkley Point A monitoring location during blast events B-BBH3 and B-BBH1**

The figures above clearly indicate that vibration levels from blasting operations are unlikely to exceed the Very Low magnitude criteria (6 mm/s) identified in Table 4. Only blast event B-BBH2 registered an observable increase in vibration above the background level at Bayleys Brook House. This maximum recorded PPV level (0.201 mm/s) is below the 0.3 mm/s level that BS 5228-2 suggests *"…might be just perceptible in residential environments"*. It is however above 0.14 mm/s, the level at which BS 5228-2 states that *"…might be just perceptible in the most sensitive situations for most vibration frequencies associated with construction."*

It should be noted that good practice for community relations and health and safety, i.e., notifying the community of planned blast events, and the pre-blast alarm, both serve to raise the sensitivity of local residents to both noise and vibration. Therefore, vibrations may have been perceived by alerted residents.

Peak vibration levels from the blast events are more clearly discernible in the measurement data obtained at the Hinkley Point A monitoring location, approximately half the distance (but in a different direction) from the blast site. However, the generated vibration levels at this location were again well below the Very Low magnitude criteria (6 mm/s).

It is difficult to be certain of the exact cause of the measured L_{Amax} during a given 1-minute measurement period. However, the maximum A-weighted instantaneous noise level at Bayleys Brook House did not exceed 65 dB $L_{Amax,T}$ as a result of the trial blasts.

Overall, it is concluded that the vibration magnitude of blast events, although possibly perceptible to alerted residents, was determined to be Very Low in relation to nuisance impacts. Cosmetic damage to buildings is highly unlikely as threshold values for buildings are much higher than those for perception and disturbance used in this study.

APPENDIX 11C: INTRODUCTION TO NOISE AND VIBRATION PRINCIPLES

Introduction to noise and vibration principles

Noise

1.1.1 Between the quietest audible sound and the loudest tolerable sound, there is a million to one ratio in sound pressure (measured in pascals, Pa). Because of this wide range, a noise level scale based on logarithms is used in noise measurement called the decibel (dB) scale. Audibility of sound covers a range of approximately 0 to 140 dB.

1.1.2 The human ear system does not respond uniformly to sound across the detectable frequency range and consequently instrumentation used to measure noise is weighted to represent the performance of the ear. This is known as the 'A weighting' and annotated as dB L_A.

Table 11C.1 Sound pressure level in dB L_A for common situations

Typical Noise Level, dB L_A	Example
0	Threshold of hearing
30	Rural area at night, still air
40	Public library Refrigerator humming at 2 m
50	Quiet office, no machinery Boiling kettle at 0.5 m
60	Normal conversation
70	Telephone ringing at 2 m Vacuum cleaner at 3 m
80	General factory noise level
90	Heavy goods vehicle from pavement Powered lawnmower, operator's ear
100	Pneumatic drill at 5 m
120	Discotheque – 1 m in front of loudspeaker
140	Threshold of pain

1.1.3 The noise level at a measurement point is rarely steady, even in rural areas, and varies over a range dependent upon the effects of local noise sources. Close to a busy motorway, the noise level may vary over a range of 5 dB L_A, whereas in a suburban area this may increase up to 40 dB L_A and more due to the multitude of noise sources in such areas (cars, dogs, aircraft etc.) and their variable operation. Furthermore, the range of night-time noise levels will often be smaller and the levels significantly reduced compared to daytime levels. When considering environmental noise, it is necessary to consider how to quantify the existing noise (the ambient noise) to account for these second to second variations.

1.1.4 A parameter that is widely accepted as reflecting the underlying background noise level is the L_{A90} index. This is the noise level exceeded for 90% of the measurement period and generally reflects the noise level in the lulls between individual noise events. Over a 1-hour period, the L_{A90} will be the noise level exceeded for 54 minutes.

1.1.5 The equivalent continuous A-weighted sound pressure level, L_{Aeq}, is the single number that represents the total sound energy measured over that period. L_{Aeq} is the sound level of a notionally steady sound having the same energy as a fluctuating sound over a specified measurement period. It is commonly used to describe environmental noise from individual sources that vary in level over their operational cycle.

1.1.6 The index historically adopted by the government since the early 1970s to assess road traffic noise is the L_{A10}. This is the noise level exceeded for 10% of the measurement time, over a 1-hour period the L_{A10} will be the noise level exceeded for 6 minutes.

1.1.7 Time weighting determines how quickly the sound level meter responds to changes in noise level. The ‘fast’ time weighting averages the measured level every eighth of a second, whereas the ‘slow’ weighting averages every one second. The ‘fast’ time weighting most closely follows the response of the human ear to sound level changes and is most commonly specified for environmental noise measurement purposes (including the L_{A10} and L_{A90} statistical parameters).

1.1.8 Most environmental noise measurements and assessments are undertaken in ‘free-field’, away from any existing reflecting surfaces (other than the ground). However, it is sometimes necessary to consider noise levels immediately external to a façade when considering the impact on residents inside properties and this normally requires the addition of up to 3 dB L_A to the predicted (or measured) free-field level due to noise reflection from the façade. The assessment of road traffic noise in the UK, for example, is based on a predicted (or measured) ‘façade’ noise level (using the L_{A10} statistical parameter).

1.1.9 Human subjects, under laboratory conditions, are generally only capable of noticing changes in steady levels of 3 dB L_A or more (PPG 24, 1994)2. It is generally accepted that a change of 10 dB L_A in an overall, steady noise level is perceived to the human ear as a doubling (or halving) of the noise level (PPG 24, 1994). (These findings do not necessarily apply to transient, non-steady or intermittent noise sources).

Vibration

1.1.10 When an object is in contact with a vibrating surface it is displaced about its reference (stationary) position. Displacement (in mm) is therefore one parameter that can be used to describe the magnitude of a vibration. For sinusoidal signals, displacement, velocity (m/s) and acceleration (m/s^2) amplitudes are related mathematically by a function of frequency and time. If phase is neglected (as is always the case when making time-averaged measurements), then the velocity can be obtained by dividing the acceleration signal by a factor proportional to frequency (measured in Hertz, Hz) and the displacement can then be obtained by dividing the acceleration signal by a factor proportional to the square of frequency.

1.1.11 For a complex acceleration signal giving rise to a complicated time history, there are several additional quantities that may be used to describe the vibration:

- The root mean square value (rms) is obtained by taking the square root of the mean of the sum of the squares of the instantaneous acceleration measured during the total measurement time (T);
- The peak value is the maximum instantaneous acceleration measured during the measurement time, (T). It is a useful indicator of the magnitude of short duration shocks;
- The Peak Particle Velocity (PPV) is the maximum instantaneous velocity of a particle at a point during a given time interval.

1.1.12 The limit of human perception to vibration is of the order of 0.15 mm/s to 0.3 mm/s PPV, in the frequency range 0.1 Hz to 1500 Hz. The human body is not equally sensitive to all frequencies of vibration and weighting curves to reflect the frequency dependency of the body have been developed and are contained within International Organisation of Standardisation (ISO) Standards. The weighting gives a good correlation between the measured vibration level and the subjective feeling or impact produced by the vibration.

1.1.13 The weightings can be incorporated into modern vibration meters, thus enabling measurement of vibration levels that correspond to human perception. Those vibrations occurring between 1-80 Hz are of particular interest when measuring exposure to whole-body vibration.

1.1.14 Vibration-induced damage to buildings can arise in different ways, making it difficult to arrive at universal criteria that will adequately and simply indicate damage risk. Damage can occur directly due to high dynamic stresses, due to accelerated ageing or indirectly when high quasi-static stresses are induced by, for example, soil compaction.

1.1.15 Figure B.1 of British Standard BS 5228: 2009 'Code of practice for noise and vibration control on construction and open sites', Part 2. 'Vibration' indicates, for example, that for a residential building (line 2) a PPV of greater than 15 mm/s at 4 Hz or greater than 50 mm/s at 40 Hz or above, measured at the base of the building, may be expected to result in cosmetic damage.

APPENDIX 11E: DETAILED CONSTRUCTION NOISE MODELLING

Construction Noise Prediction Modelling Using CadnaA Software

a) Objective

The objective of the noise prediction modelling exercise was to predict construction noise levels at discrete points in time during the preliminary works and HPC construction phase at the nearest noise sensitive receptor locations. This exercise is intended to be supplemental to the detailed construction noise calculations presented in **Appendix 11D** of **Chapter 11, Volume 2** of the Environmental Statement. The following scenarios were assessed:

Scenario A (approx. Q4 2011) - two months into preliminary works, assuming the following activities:

- residual hedge and tree removal;
- stripping of topsoil;
- topsoil stockpiling at both at the southern operational extent of the Southern Construction Phase Area (latitude 144750mN) and at the western boundary of the Southern Construction Phase Area; and
- preparation works for construction of the northern roundabout close to Pixies Mound.

Scenario B (approx. Q2 2012) **-** six months into preliminary works, assuming the following activities:

- deep (rock) excavation would be ongoing at UK EPR Units 1 and 2;
- excavated materials would continue to be transported to the stockpiles within the Southern Construction Phase Area;
- dump truck using circular haul route between northern and southern land; and
- site levelling at the site of the proposed southern access roundabout.

Scenario C (approx. Q2 2013) - During this phase of works, the following activities are assumed to be ongoing:

- deep excavation and concrete substitution at the location of the UK EPR reactor units;
- construction of temporary and permanent ancillary buildings;
- operation of the temporary jetty;
- tunnelling and construction of the cooling water inlet and outlets;
- construction of the National Grid 400kV substation;
- construction of the on-site accommodation campus; and
- distribution of removed overburden, and storage on the SCPA land.

Scenario D (approx. Q4 2014) - During this phase of works, the following activities are assumed to be ongoing:

- construction of nuclear island buildings;

- construction of temporary and permanent ancillary buildings;
- operation of the temporary jetty;
- construction of the National Grid 400kV substation;
- tunnelling and construction of the cooling water inlet and outlets;
- distribution of removed overburden, and storage on the SCPA land; and
- occupation of the on-site accommodation campus.

Scenario E (approx. Q4 2014) **–** During this phase of works, the following activities are assumed to be ongoing and the night-time construction/maintenance activities would be undertaken:

- construction of nuclear island buildings;
- construction of temporary and permanent ancillary buildings;
- operation of the temporary jetty;
- occupation of the on-site accommodation campus;
- tunnelling and construction of the cooling water inlet and outlets; and
- distribution of tunnel arisings to the fresh rock stockpile area south of Green Lane.

Construction machinery type and numbers assumed for each assessed scenario were in accordance with equipment list for the respective activities presented in Table 11D.9 of **Appendix 11D**.

b) Noise prediction modelling software and calculation methodology

Noise propagation calculations were undertaken in accordance with British Standard BS5228:2009 'Noise and vibration control on construction and open sites' - Part 1 'Noise', which is embedded as a software module.

Predictions of construction noise levels at the receptor locations take account of features that may affect propagation, such as ground absorption; and, screening by the natural and/or formed topography. Other factors, such as the length of the working, traverse and the machinery 'on-time' are also included within the calculations. For this study, it was assumed that all plant and machinery are operating continuously over a 1-hour period, therefore no 'on-time' correction was applied.

Predicted noise levels are therefore a worst case basis and in practice the actual noise levels may not attain those predicted. It should be noted that predicted noise levels are based upon the assumption that standard good construction practice measures will be applied. Such measures to control noise impacts are outlined in BS5228-1:2009. Therefore, source noise data, used in the construction noise calculations, for specified plant (provided in BS5228-1) is based upon well-maintained equipment, and where appropriate integral acoustic enclosures. It should be noted that, in applying the BS5228-1:2009 noise prediction calculation methodology, a maximum screening attenuation of 10dB is used. In reality, attenuation due to screening (for example, by topographical features) might be significantly higher than calculated. The predicted construction noise levels are therefore considered to be overestimated and precautionary.

c) Modelling parameters

i. Modelling the topography

The existing topography of was modelled using 1m LIDAR (Light Reflection and Ranging) data. Beyond this area, 10m Ordnance Survey contours were imported into the model. For each assessed scenario, the local topography of both the northern Built Development Area East and West) and southern land (Southern Construction Phase Area) was adjusted.

Overall, the general gradient change is from the north (sea level) to the south, where the nearest sensitive receptor buildings are located at a level of 20 – 30 m AOD.

ii. Modelling buildings and other obstacles

Existing buildings and cylinders (including chimney stacks) were incorporated within the model. The location and 2-dimensional extent of existing building were based on the 1:10,000 colour raster Ordnance Survey tile.

The height of buildings located on the existing Hinkley Point A and B power stations have been estimated, whilst the height of all sensitive receptor buildings have been set to 6m, allowing for properties of up to two storeys.

iii. Modelling noise sources (emission points)

The following two types of noise sources were included in the model:

- Point sources (construction equipment and machinery)
- Line sources (haul roads)

Octave band noise emission data for each type of construction and earthworks machinery (for example: bulldozers, excavators and dump trucks) were obtained from the Appendices of BS5228-1:2009, where available. The octave sound power levels for equipment assumed in each model scenario (see Tables 11E.1 to 11E.2) are presented in Table 11E.3.

Table 11E.1: Hinkley Point C construction phase noise sources assumed for each assessed scenario

Machinery	Number of operating noise sources				
	A	B	C	D	E
17t Scraper	10	8	0	0	0
28t Dozer	11	10	6	6	2

Note: * Sound power level per square metre (dB/m^2)

d) Other modelling parameters

i. Ground absorption

All land outside of the HPC development site and the existing nuclear power generation sites at Hinkley Point was assigned a sound absorption factor of 1.00 (soft ground) for the purpose of noise propagation calculations. Land within the construction area, including the Southern Construction Phase Area was assigned an absorption factor of 0.25.

ii. Meteorological conditions

Annual hourly sequential meteorological data which was generated using the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction Model for the Hinkley Point site was used to define meteorological condition in the noise propagation model. This dataset provides sequential hourly of data (from 1 January 2004 to 31 December 2008).

The following meteorological conditions were assumed:

- Temperature: 10ºC (average temperature 2004 – 2008 inclusive was 11.3ºC).
- Relative Humidity: 70% (average relative humidity 2004 – 2008 inclusive was 77.5%)

iii. Foliage/woodland areas

Areas of existing foliage have been identified within the model. However, these areas have no acoustic features and are therefore not accounted for within noise propagation calculations.

iv. Reflections

Given the distance separation between the Built Development Areas and the nearest noise sensitive receptors, a single order of reflection was permitted within the model.

e) Noise sensitive receptor locations (immission points)

Immission points are positions of noise reception calculation. Modelled prediction calculations determine both the broadband noise and the octave band data at each immission point resulting during each assessed construction scenario.

Immission points were positioned in free-field (i.e. greater than 3.5 m from any reflecting surface other than the ground) at three residential receptor locations and four public amenity locations (footpaths, permissive routes and Pixies Mound). These positions are defined in Table 11E.4 below, and shown in **Figure 11.1** of the ES.

Table 11E.4 Noise Immission Points

Receptor location	Ref.	Ordnance Survey co-ordinates		
		x	y	z (relative to local ground level), m
Knighton Farm	R9	320598.6	144714.1	1.8
Bishops House Farm	R10	319375.7	144513.5	1.8
Doggetts	R7	320092.1	144405.7	1.8
Benhole Lane (south) - public footpath	R5	319714.8	144975.3	1.8
Benhole Lane (north) - public footpath	R4	319535.8	145806.0	1.8
Coastal footpath	R1	319857.7	146151.8	1.8
Pixies Mound	R3	320890.2	145573	1.8

f) Model outputs

Table 11E.5 summarises the construction noise levels, predicted using CadnaA modelling in accordance with BS 5228-1, at each selected receptor location during each assessed scenario. The predicted noise levels are worst-case, assuming that all plant and machinery is operating.

Table 11E.5 Summary of predicted Hinkley Point C construction noise levels at identified sensitive receptor locations (excluding existing ambient noise)

Ref.	Receptor	Type	Predicted $L_{Aeq,T}$ Sound Pressure Level, dB (Free-field)				
			A	B	C	D	E
R9	Knighton Farm	Private residential	52	56	54	46	39
R10	Bishops House Farm	Private residential	49	49	46	47	39
R7	Doggetts	Private residential	47	48	44	43	38
R5	Benhole Lane (south)	Outdoor amenity - Public footpath/PRoW	61	61	54	59	50
R4	Benhole Lane (north)	Outdoor amenity - Public footpath/PRoW	65	57	58	62	58
R1	Coastal footpath	Outdoor amenity - Public footpath/PRoW	60	53	54	57	52
R3	Pixies Mound	Outdoor amenity - Historical feature	69	57	59	61	52

Table 11E.6 below shows the effect of adding measured typical ambient daytime noise levels to these values and therefore provides an indication of potential impacts when compared with magnitude threshold values.

Table 11E.6 Summary of predicted ambient noise levels at identified sensitive receptor locations during Hinkley Point C construction (including existing ambient noise)

Ref.	Receptor	Type	Predicted $L_{Aeq,T}$ Sound Pressure Level, dB (Free-field)

R3	Pixies Mound	Outdoor amenity - Historical feature	69	58	59	61	52

Predicted site preparation noise levels include the arithmetic mean of the measured baseline ambient daytime noise levels ($L_{Aeq,15min}$) at receptor locations between 07:00 and 19:00. Ambient daytime noise levels:

- Knighton Farm = 46 dB $L_{Aeq,T}$;
- Doggetts = 45 dB $L_{Aeq,T}$;
- Bishops Farm House = 41 dB $L_{Aeq,T}$;
- Benhole Lane (S) = 41 dB $L_{Aeq,T}$;
- Benhole Lane (N) and coastal footpath = 43 dB $L_{Aeq,T}$; and
- Pixies Mound = 49 dB $L_{Aeq,T}$.

Figures 11.3 to **11.7** show CadnaA noise contour plots, excluding existing ambient noise levels, for each assessed scenario, modelled at a height of 4 m above ground level. The predicted noise levels are worst-case, assuming that all plant and machinery is operating.

APPENDIX 11F: DETIALED OPERATIONAL NOISE MODELLING

1.1 Operational noise prediction modelling using Cadna A software

a) Objective

The objective of the noise prediction model was to determine the overall noise contribution from all operational sources associated with both proposed UK EPR units at the nearest noise sensitive receptor locations.

b) Noise prediction modelling software and calculation methodology

The Hinkley Point C (HPC) noise modelling study utilised Cadna A noise prediction model (Version 4) software, created by DataKustik GmbH, Germany. Noise propagation calculations were undertaken in accordance with the International Standards Organisation guidance document ISO 9613: Part 2: 1996 'Attenuation of sound during propagation outdoors' (Ref. 11F.1).

ISO 9613 specifies an engineering method for calculating the attenuation of sound during propagation outdoors, in order to predict the levels of environmental noise at a distance from a variety of sources. The method predicts the sound pressure level under meteorological conditions favourable to propagation from source to the receiver. These conditions are for downwind propagation, as specified in 5.4.3.3 of IS0 1996/BS 7445 or, equivalently, propagation under a well-developed moderate ground-based temperature inversion, such as can occur at night.

The method specified in part 2 of IS0 9613 consists specifically of octave-band algorithms (with nominal mid-band frequencies from 63 Hz to 8 kHz) for calculating the attenuation of sound that originates from a point sound source, or an assembly of point sources. The source (or sources) may be moving or stationary. Specific terms are provided in the algorithms for the following physical effects:

- geometrical divergence A_{div};
  - $A_{div} = [20 \log(d/d_0) +11]$ dB
  - where: d= the distance from source to receiver (m) and d_0 is the reference distance (1m).
- atmospheric absorption Aatm;
  - $A_{atm} = \alpha d/1000$
  - where; α = the atmospheric absorption coefficient (dB Km^{-1}), d = distance in metres.
- ground effect A_{gr};
  - A_{gr} = A, + A, + A,
  - Where A, = attenuation in the source region, A, = attenuation in the receiver region and A, = attenuation in the middle region.
- screening by obstacles A_{bar};
  - Where A_{bar} is calculated using an octave band based Makaewa/fresnel number based algorithm taking into account diffraction over the top and around the edges of any barrier.

Additionally the methodology includes allowances for reflection of sound off surfaces in the vertical plane (reflections off the ground and in the horizontal plane are allowed for in the calculation of the ground effect).

The ISO 9613 method is applicable in practice to a great variety of noise sources and environments. It is applicable, directly or indirectly, to most situations concerning road or rail traffic, commercial and industrial noise sources, construction activities, and many other ground-based noise sources.

The calculation of the equivalent continuous downwind sound pressure level at a receiver location, L_{AT}(DW), is calculated for each point source, using:

$$L_{AT}(DW) = L_w + D_c - A$$

Where:

L_w, is the octave-band sound power level, in decibels, produced by the point sound source relative to a reference sound power of one picowatt (1 pW);

D_c is the directivity correction, in decibels, that describes the extent by which the equivalent continuous sound pressure level from the point sound source deviates in a specified direction from the level of an omni-directional point sound source producing sound power level L_w; D_c equals the directivity index D_I of the point sound source plus an index D_Ω, that accounts for sound propagation into solid angles less than 4π steradians; for an omni-directional point sound source radiating into free space, D_c, = 0 dB. Where sources are immediately external to building elements (façades/roof), the model includes directivity (i.e. $D_c = 3$);

A is the octave-band attenuation, in decibels, that occurs during propagation from the point sound source to the receiver.

The attenuation term A is given by:

$$A = A_{div} + A_{atm} + A_{gr} + A_{bar} + A_{mis}$$

Where:

- A_{div} is the attenuation due to geometrical divergence;
- A_{atm} is the attenuation due to atmospheric absorption;
- A_{gr} is the attenuation due to the ground effect;
- A_{bar} is the attenuation due to a barrier; and
- A_{mis} is the attenuation due to miscellaneous other effects.

c) Modelling parameters

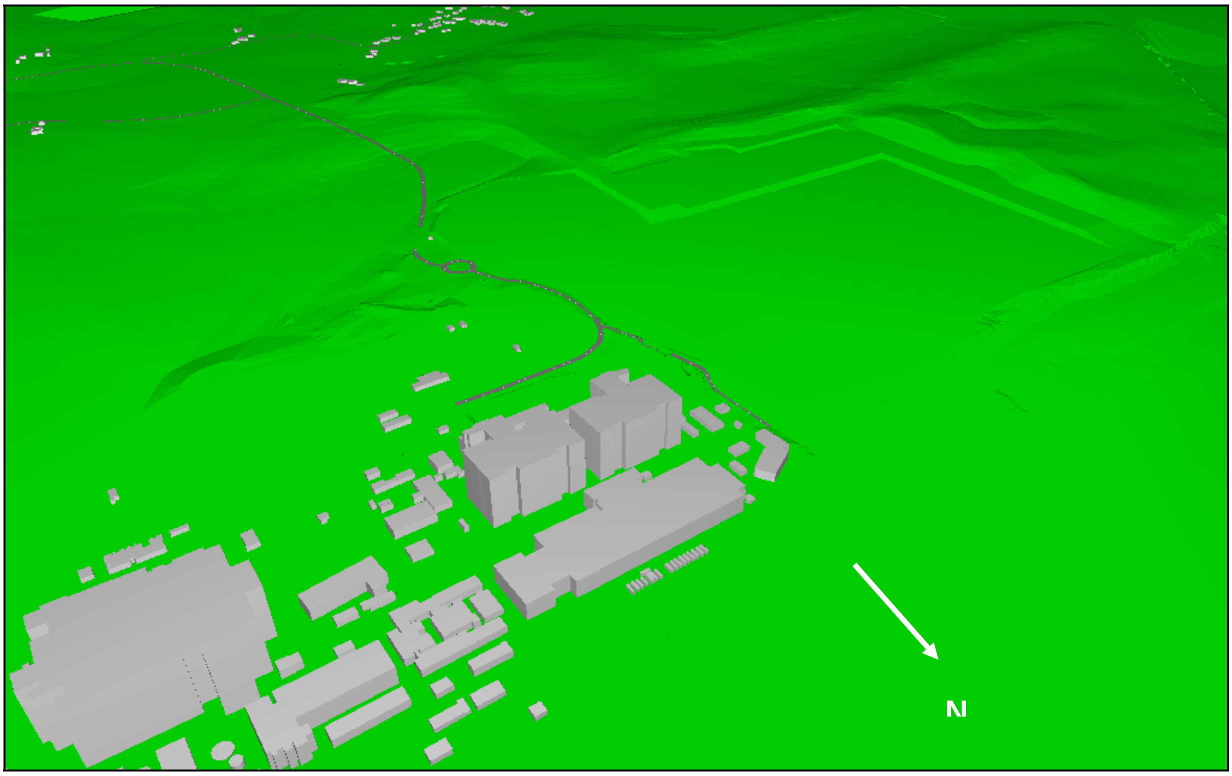
i. *Modelling the topography*

The existing topography of was modelled using 1m LIDAR (Light Detection and Ranging) data. Beyond this area, 10 m Ordnance Survey contours were imported into the model. The local topography of the Hinkley Point C site was adjusted in light of design decisions, including a +14.00m AOD level for the nuclear island platform, and other terracing for permanent ancillary buildings, the landscape restoration plan and site layout plan (see **Volume 2, Chapter 2** of the ES).

Overall, the general gradient change is from the north (sea level) to the south, where the nearest sensitive receptor buildings are located at a level of 20 – 30m AOD. The modelled contours for the site and surrounding land are shown in **Plate 11F.1** and represented in a 3-dimensional view in **Plate 11F.2**.

Plate 11F.1: Topographical model showing proposed development height contours

Plate 11F.2: 3D image of the topography with proposed Built Development Area platforms



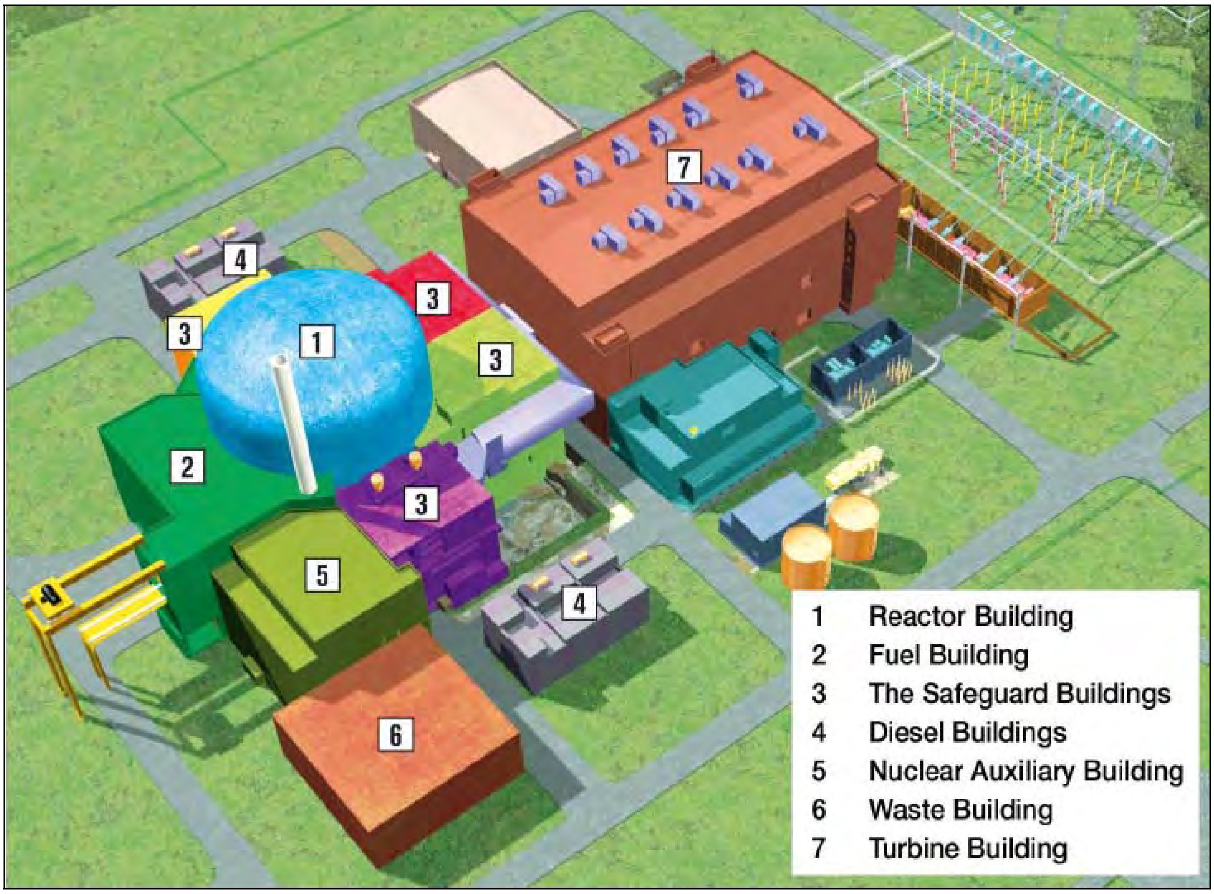
ii. *Modelling buildings and other obstacles*

Existing and proposed buildings and cylinders (including chimney stacks) were incorporated within the model based on the HPC site layout plan as presented in **Chapter 2** of the ES. The location and 2-dimensional extent of existing building were based on the 1:10,000 colour raster Ordnance Survey tile.

The height of buildings located within the existing Hinkley Point Power Station Complex have been estimated, whilst the height of all sensitive receptor buildings have been set to 6 m, allowing for properties up to two storeys.

A typical UK EPR plant configuration image is presented in the Pre-Construction Environmental Report (Sub-Chapter 1.2, Figure 1). This image is replicated in **Plate 11F.3** below. It should be noted however that, as a result of ongoing engineering and architectural studies at this and other EPR construction sites, **Plate 11F.3** does not accurately represent the proposed nuclear island design of HPC UK EPR units (as shown in **Plates 11F.4 and 11F.5**).

Plate 11F.3: Typical UK EPR plant configuration



The full complement of proposed buildings, chimney stacks and tanks associated with the HPC development, including relative height data, is provided in **Tables 11F.1 and 11F.2** below.

The proposed Nuclear Island and Conventional Island buildings as modelled in the assessment are presented in **Plate 11F.4** below. **Plate 11F.5** shows a 3-dimensional graphic of the buildings in the nuclear island.

Plate 11F.4: Building model showing the layout of the proposed HPC nuclear island and ancillary buildings

Plate 11F.5: 3D image of proposed HPC Nuclear Island and ancillary buildings

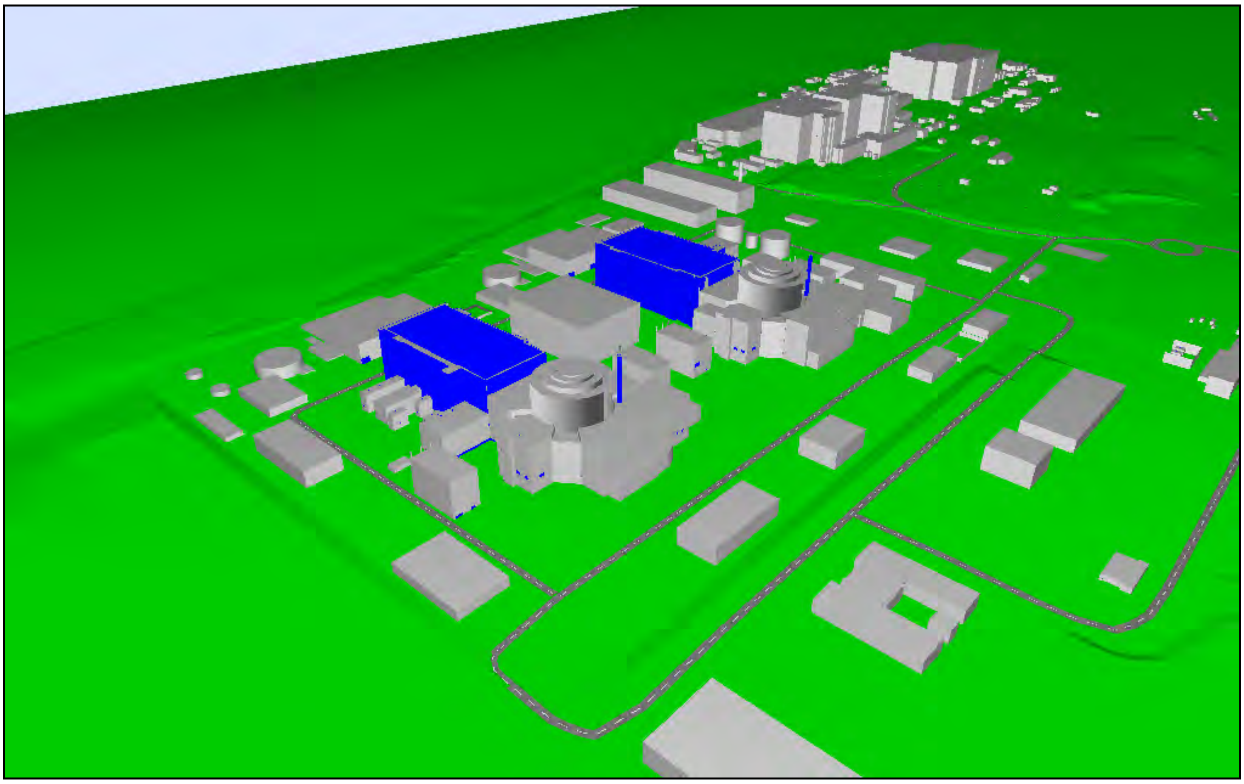

Plate 11F.6 below identifies the location of the noise sensitive receptor (R) and baseline monitoring (ML) locations used in the impact assessment and their respective position relative to the existing and proposed nuclear power generation sites.

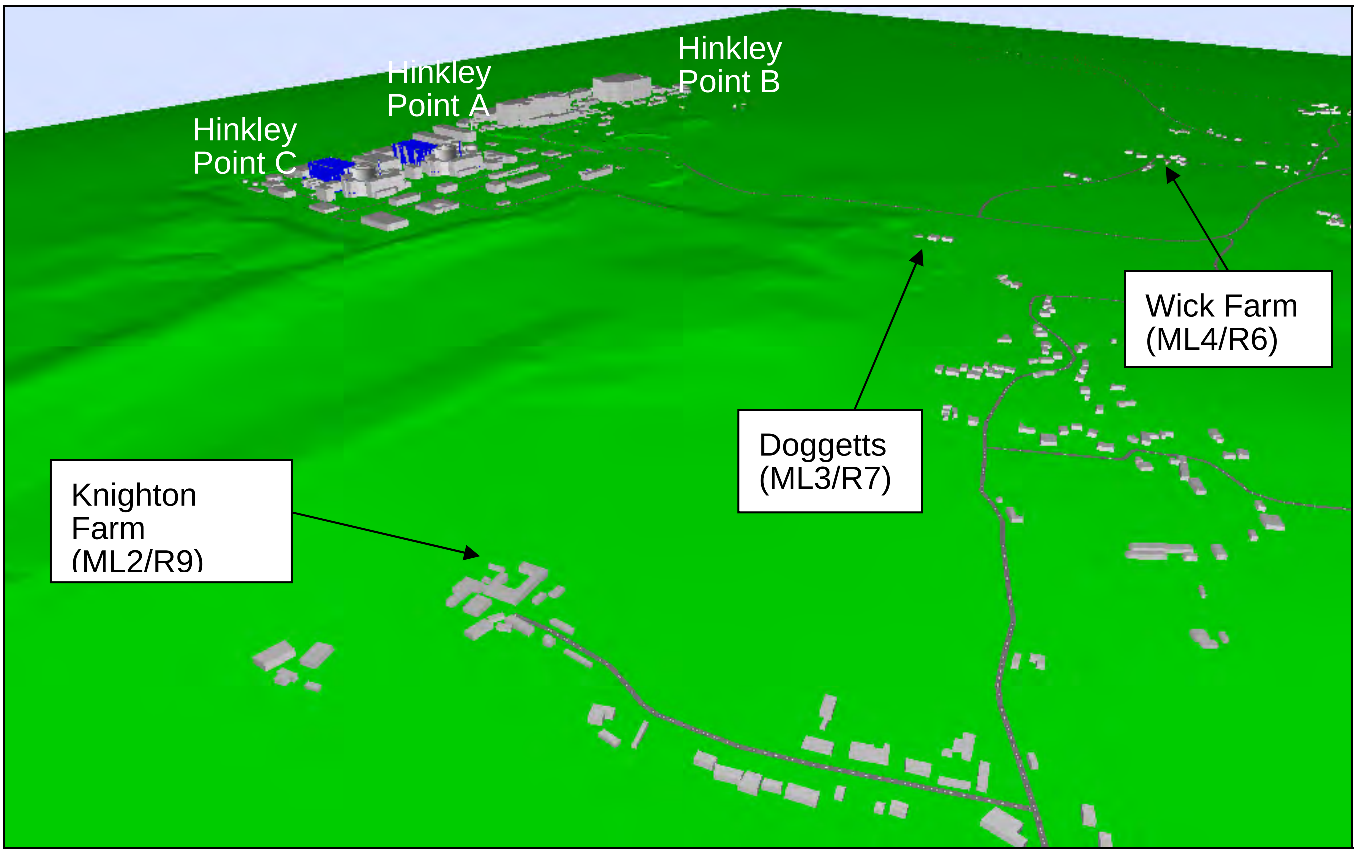
Plate 11F.6: 3D image of noise sensitive receptor locations and proposed HPC



iii. *Modelling noise sources (emission points)*

Three types of noise sources were included in the model, including:

- Point sources;
- Area sources – vertical area sources were used to model openings and air vents in building façades;
- Line sources – used for pipelines; and
- The directivity of noise emissions was based upon the source type (e.g. chimney stack exit or building façade) and the source location (openings in building façades).

Octave band noise emission data was derived from 1/3rd octave band data presented in an acoustic assessment report for a proposed EPR development at Penly, France. This report also defined the dimensions and height of each individual noise source. Individual noise sources associated with the proposed Nuclear Island and Conventional Island for a single UK EPR unit are presented in **Table 11F.3** below.

Table 11F.3: Noise sources of a single UK EPR unit

Building			Noise sources	Sound Power Level dB L_{WA}
Nuclear island	Nuclear auxiliaries building	HN	Refrigerant group DER	102.1 per unit
			Hopper HNX	87.7
	Fuel building	HK	Chimney - Chimney stack - Chimney opening	104.9, made up of: 91.3 104.7
	Electrical building	HLA	Hopper	91.3
		HLB	Air inlet	89.9
		HLC	Air inlet	89.9
		HLD	Hopper	88.9
			Air outlet	95
		HLA and HLD	Refrigerant group DEL	101.4 per unit
		HLA and HLC	Hopper	96.3
	Diesel	HDA and HDB	Hopper 01VB	89.4 per opening
			Hopper 01VB	87.7 per opening
			Hopper 03VB	105 per opening
		HDC and HDD	Hopper 01VB	89.4 per opening
			Hopper 01VB	87.7 per opening
			Hopper 03VB	105 per opening
	Above the electrical buildings		Steam piping Division 1	82.6
			Steam piping Division 2	82.4
			Steam piping Division 3	82.4
			Steam piping Division 4	82.6
	Spent fuel building	HHK	Air-water heat exchanger towers (4 towers each containing 2 exchangers)	102.8 per exchanger unit
Conventional island	Turbine hall	HM	Facades and roof	94.1
			Roof vents (40 vents per EPR unit)	91.0
			Lamellae (2 lamellae per EPR unit – NE and SW)	97.4
	Unclassified Electrical Building	HF	Refrigerant group	88.8 per unit
	Pumping station	HP	Pumping station	90.3
	Main transformer	HT	Pole TP	105.2 per unit

Building			Noise sources	Sound Power Level dB L_{WA}
			Ventilation TP	88.2 per unit
	Step down transformer		Pole TS	98 per unit
			Ventilation TS	88.7 per unit
	Auxiliary transformer	HJ	Pole TA	98
			Ventilation TA	88.7 per unit
	POE		Refrigerant group	101.4 per unit
National Grid Substation	Series Inductors		Inductor	100 dB per unit

This broadband sound power level from each building was further distributed between the discrete sound emitting elements. The octave band data for each of these elements as used in the noise prediction model are presented in **Table 11F.4** below.

A number of worst-case assumptions were made regarding operation of some noise sources listed in **Table 11F.3**. Notably, it was assumed that four of the eight emergency diesel generators (EDGs) and two of four Station Black Out (SBO) generators are in operation. This is safety equipment, providing backup power supply in the unlikely event of loss of the main off-site power supply when house load operation fails, so that the EPR unit can be secured and the reactor cooled. These backup generators routinely operate during periodic tests, which represent an estimated 60 hours per year for each of the EDGs and SBO generators. Each EDG and SBO will also be operational for 242.5 hours per year and 738 hours per year, respectively, during the initial commissioning of the plant.

Similarly, it is assumed that eight of the 12 heat exchangers associated with the spent fuel building are in operation. However, ventilation will only be required during periods of high ambient air temperature and/or on occasions of large inventory stored in the cooling ponds. It should be noted that operation of all 12 heat exchangers would only occur in the event of an emergency.

d) Other modelling parameters

i. *Ground absorption*

All land outside of the Development Site and the existing Hinkley Point Power Station Complex was assigned a sound absorption factor of 1.00 (soft ground) for the purpose of noise propagation calculations. The remaining ground was assigned a ground absorption factor of 0.20, to account for hard surfaces and small obstacles (machinery, vehicles etc). Areas supporting pylons and other electrical plant on the proposed substation site were assigned a ground absorption of 0.5 as these will be covered by stone chippings.

ii. *Meteorological conditions*

Annual hourly sequential meteorological data which was generated using the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction Model for the Hinkley Point site was used to define meteorological condition in the noise propagation model. This dataset provides sequential hourly of data (from 1 January 2004 to 31 December 2008). The industrial noise calculation utilises the ISO 9613-2 methodology for the determination of meteorological correction (C_{met}).

The following meteorological conditions were assumed:

- Temperature: 10ºC (average temperature 2004 – 2008 inclusive was 11.3ºC). Ambient temperature is used in the prediction and calculation of sound emission directivity from exhaust stacks.
- Relative Humidity: 70% (average relative humidity 2004 – 2008 inclusive was 77.5%).

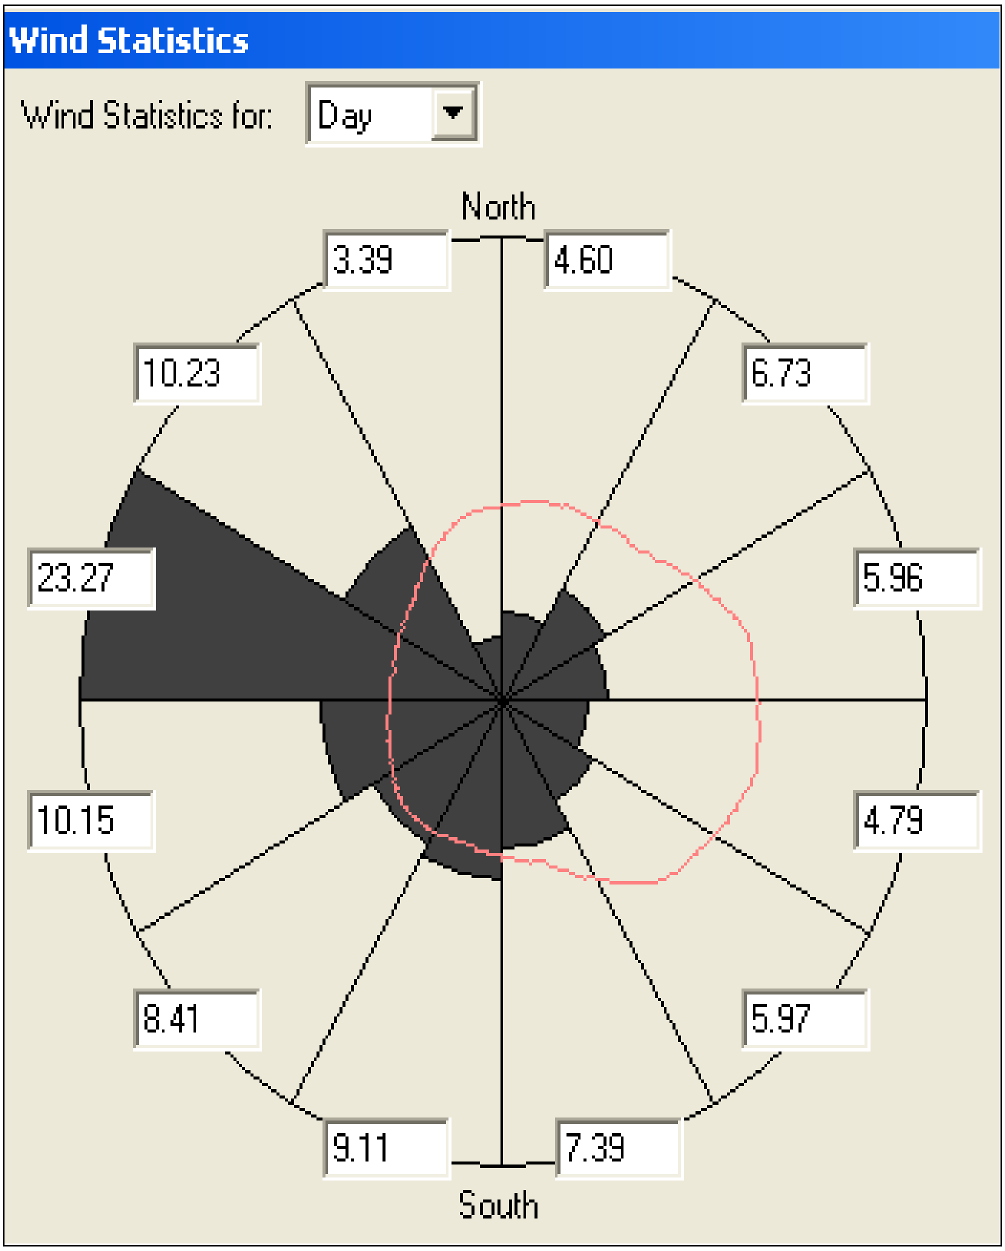
Additional sensitivity testing was undertaken to indicate the effects of wind parameters on predicted noise levels at each receptor location. BS 4142 does not specify a calculation methodology for determining the effects of meteorology on noise propagation, except for a recommendation that the calculation method adopted should be reported and reasoned appropriately. Noise propagation calculations were therefore undertaken using the following methodologies:

1) Average wind direction: The ISO 9613-2 method for determination of C_{met} based on local meteorological conditions provides the most realistic assessment of long-term noise propagation. This uses the proportionality of long-term wind parameter data, presented in **Plate 11F.7** below;

2) Downwind propagation: Noise propagation under downwind conditions was undertaken in accordance with ISO 9613-2: 1996, which assumes:

> *“ - wind direction within and angle of ±45º of the direction connecting the centre of the dominant sound source and the centre of the specified receiver region, with the wind blowing from source to receiver, and*
>
> *“ – wind speed between approximately 1 m/s and 5 m/s, measured at a height of 3 m to 11 m above ground.”*

Plate 11F.7: Proportion of wind direction (Hinkley Point, 2004-2008)



ISO 9613-2 indicates that, whilst meteorological effects might fall in the range of zero to approximately +5dB (C_0), “values in excess of 2 dB are exceptional”. As a typical worst case, a constant C_0 value of +2.0dB was assumed in order to derive the effects of meteorological conditions on downwind noise levels; and

3) Neutral: No wind directionality or speed was assumed.

iii. *Foliage/woodland areas*

Areas of existing foliage have been identified within the model. However, these areas have no acoustic features and are therefore not accounted for within noise propagation calculations.

iv. *Reflections*

Given the distance separation between the Built Development Areas and the nearest noise sensitive receptors, a single order of reflection was permitted within the model.

e) Noise sensitive receptor locations (immission points)

Immission points are positions of noise reception calculation. Modelled prediction calculations determine both the broadband noise and the octave band data at each immission point resulting from operation of the HPC development. The results data also provides the partial noise contributions from each significant modelled noise source.

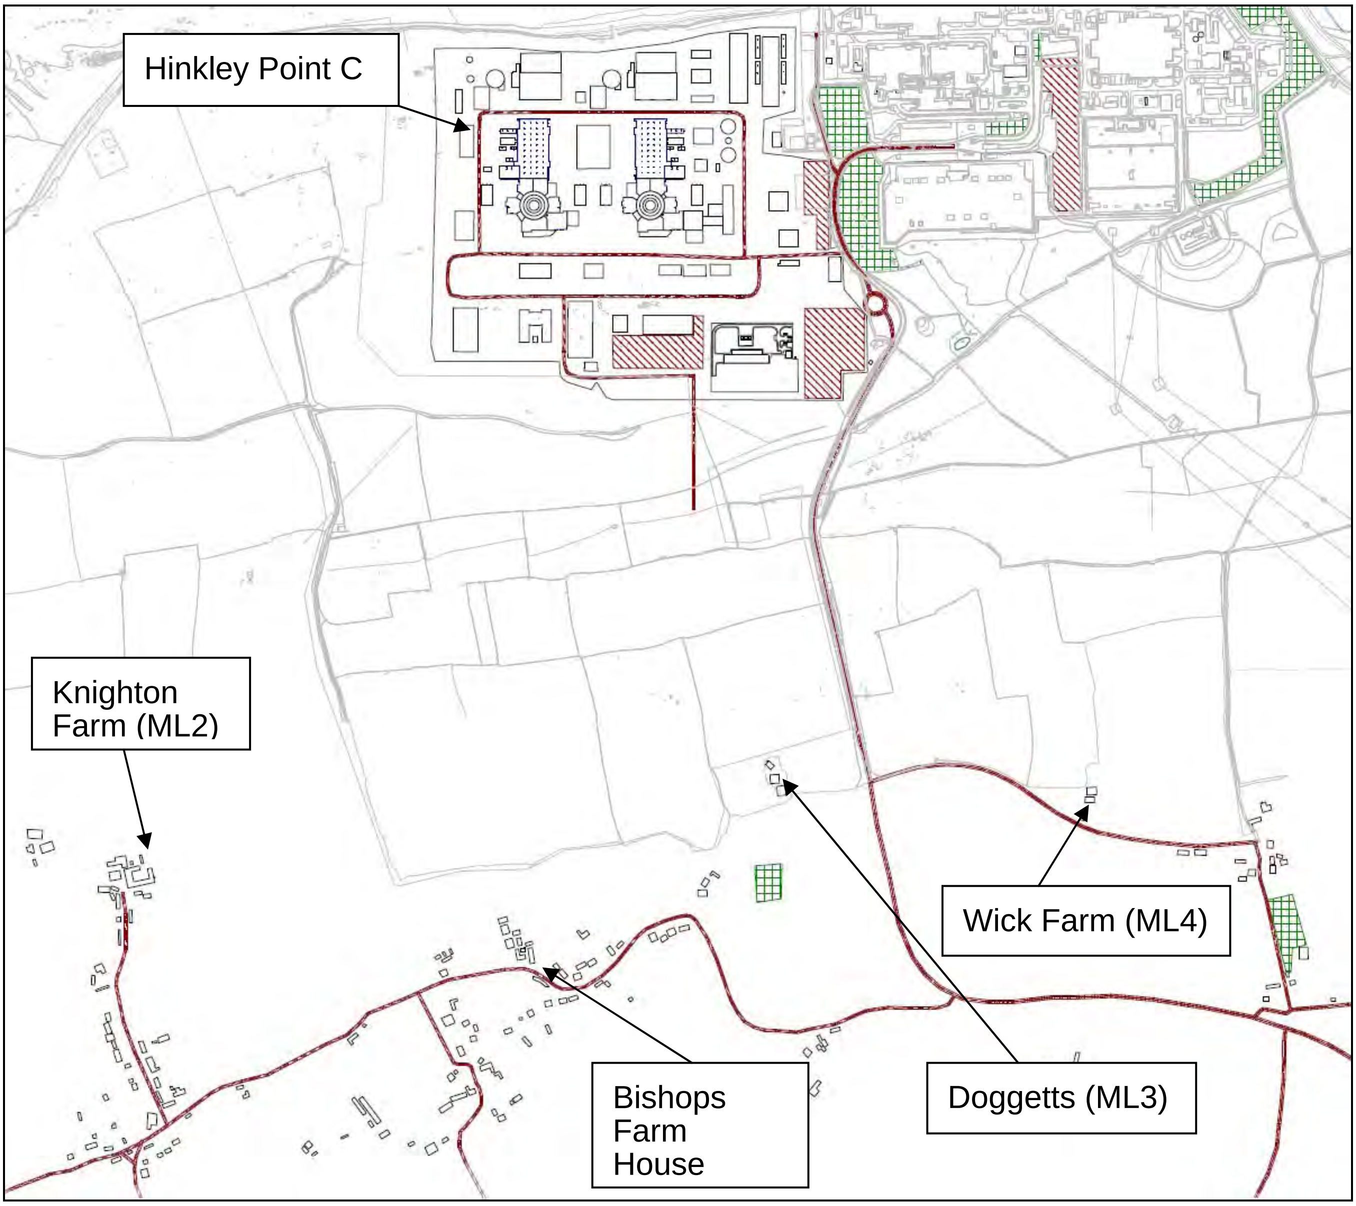
For comparison, immission points were positioned at the nearest façade of the nearest noise sensitive receptor locations for comparison with the measured baseline noise levels described in the Factual Noise Report. These positions are defined in **Table 11F.5** below:

Table 11F.5: Noise Immission Points

Receptor	Ref. (Factual Noise Report baseline data)	Co-ordinates			Position
		x	y	z (relative to local ground level), m	
Knighton Farm	ML2	319387.94	144482.17	4	1 m from Facade
Doggetts	ML3	320601.17	144711.64	1.5	
Wick Farm	ML4	321579.41	144630.40	4	

The location of each of these immission points is identified in **Plate 11F.8**:

Plate 11F.8: Location of noise immission points in relation to the proposed Hinkley Point C nuclear power station



f) Model outputs

A summary of the predicted noise levels at each receptor location under the three meteorological testing scenarios are presented in **Table 11F.6** below. Noise contour grids (10m x 10m interval, at 4 m AOD) calculated using the neutral and average wind scenarios are presented in **Figures 11.8 and 11.9**.

Table 11F.6: Predicted operational noise level at nearest receptor dwellings

Ref.	Receptor	Predicted $L_{Aeq,T}$ Sound Pressure Level, dB (Façade)		
		L_{AT}(LT) (Average wind direction)	L_{AT}(DW) Downwind	L_{AT} Neutral (no wind)
ML2/R9	Knighton Farm	33.7	36.6	35.2
ML3/R7	Doggetts	29.6	32.3	30.9
ML4/R6	Wick Farm	32.2	34.9	33.4

The predicted noise levels are worst case, assuming that all plant and machinery is operating. This includes worst case operation of emergency and stand-by generators, which will only operate for 88 hours per year during down periods.

Tables 11F.7 – 11F.9 show the partial noise levels of the 20 most significant noise sources affecting each receptor location, ranked by the broadband noise contribution under the average wind direction modelling scenario. These also include partial A-weighted octave sound pressure levels at each location attributable to each source.

Attention: Mr. Raymond Fox

Dear Ray

Re: Hinkley Point C
Noise assessment criteria
Comments and queries from ARUP (210482-03/PBA)

In response to the questions raised by your advisors (ARUP), please find below further clarifications regarding selection of noise assessment criteria and thresholds.

Construction Noise

ARUP: The presentation references Annex E of BS5228: 2009 which provides examples of thresholds of significant effects at dwellings. The proposed thresholds look to be based on the "ABC Method" but appear to be presented as actual construction limits. Clarification should be sought as to what the numbers in the two tables refer to.

The rationale behind the choice of thresholds in the tables should be sought. The numbers have close correspondence with the example figures in BS5228: 2009 with the exception of the use of 60dB (for evenings, Sundays and Bank Holidays) instead of 55dB.

The noise thresholds for Saturday afternoons are the same as weekly daytime levels. Clarification should be sought as to the reasons for not applying a reduced noise threshold for Saturday afternoons.

Advice is taken from BS5228:2009, but the proposed criteria for works on the Hinkley Point main site (including temporary construction areas) are, in general, more stringent in light of the proposed duration of construction works. If the ABC method had been adopted, the 'Category A' criteria would have been appropriate. These limits are presented in Table 1 below:

Table 1: Comparison of 'ABC Method Category A' limits and proposed Hinkley Point C main site construction noise limits

<table>
<tr><th colspan="2">Assessment Period</th><th colspan="2">Construction Noise Threshold dB $L_{Aeq,T}$ (free-field)* -</th></tr>
<tr><th>Day of Week</th><th>Time of Day</th><th>ABC Method Category A dB $L_{Aeq,T}$</th><th>Proposed Limits for Hinkley Point C Main Site</th></tr>
<tr><td rowspan="3">Monday – Friday</td><td>07.00 – 19.00</td><td>65 dB $L_{Aeq,12h}$</td><td>65 dB $L_{Aeq,1h}$</td></tr>
<tr><td>19.00 – 23.00</td><td>55 dB $L_{Aeq,4h}$</td><td>60 dB $L_{Aeq,1h}$</td></tr>
<tr><td>23.00 – 07:00</td><td>45 dB $L_{Aeq,8h}$</td><td>45 dB $L_{Aeq,1h}$</td></tr>
<tr><td rowspan="4">Saturday</td><td>07.00 – 13.00</td><td>65 dB $L_{Aeq,6h}$</td><td rowspan="2">65 dB $L_{Aeq,1h}$</td></tr>
<tr><td>13:00 – 19:00</td><td rowspan="2">55 dB $L_{Aeq,10h}$</td></tr>
<tr><td>19.00 – 23.00</td><td>60 dB $L_{Aeq,1h}$</td></tr>
<tr><td>23.00 – 07:00</td><td>45 dB $L_{Aeq,8h}$</td><td>45 dB $L_{Aeq,1h}$</td></tr>
<tr><td rowspan="3">Sunday and Bank Holidays</td><td>07.00 – 19.00</td><td rowspan="2">55 dB $L_{Aeq,12h}$</td><td>60 dB $L_{Aeq,1h}$</td></tr>
<tr><td>19.00 – 23.00</td><td>55 dB $L_{Aeq,1h}$</td></tr>
<tr><td>23.00 – 07:00</td><td>45 dB $L_{Aeq,8h}$</td><td>45 dB $L_{Aeq,1h}$</td></tr>
</table>

As the ABC method limits presented in Table 1 are averaged over the reference period (e.g. 12 hours in the case of normal weekdays), there is potential for exceeding these levels within the specified period. The shorter reference period of 1-hour for all periods as proposed would provide a more strict control on construction noise emissions throughout the long-term construction schedule. This is therefore a more stringent control during the week-day periods when the majority of works will be undertaken.

Construction works are proposed to be undertaken on a 24-hour basis, however almost all evening and night-time works will be restricted to the main site which will be floodlit. The movement of spoil, particularly within the spoil storage areas to the south of the main site will be restricted to daylight hours only.

To maintain the schedule, it will be necessary to continue spoil movements on the southern land during Saturday, Sunday and Bank Holiday daytime periods. As the limit proposed uses a 1-hour reference period, this provides a tighter control on noise emissions, and particularly which specific spoil storage areas can be used during these periods.

It should be noted that these are limits rather than target levels. As the majority of works will occur at a significant distance from neighbouring receptors, construction noise levels on the whole are predicted to be well below the proposed threshold values. The most significant impacts are predicted during deposition and compaction of stockpiles in the southernmost areas of the southern construction land. The current proposals are to use spoil to create an earth bund. Whilst this will provide a small degree of acoustic screening, once built, it will also ensure greater distance separation, and therefore greater sound attenuation, for the longer-term works.

Similar to the above, a slightly higher (+5 dB) limit is proposed for week-day evenings to enable continued movement of spoil during daylight periods. Again however, this will be more tightly controlled due to the 1-hour reference period.

The proposed night-time noise limits are as prescribed in Table 1 (BS5228:2009 ABC method) except using a 1-hour reference period for tighter control.

> *ARUP: The term 'short duration' is not defined in terms of a maximum noise level of 75dB(A) for specific noisy works.*

"Short duration" refers to the 1-hour reference period (T), which is stated in the footnote to the table. Specific noisy works, primarily blasting events during site platform construction and nuclear island deep excavations, may occur intermittently during the construction works (approximately 14 months). Planned noisy events will be undertaken during daytime periods only, and neighbouring receptors will be notified at least 48 hours in advance.

> *ARUP: Clarification should be sought for the use of the time periods and the difference in time periods for Hinkley Point C site and Combwich Wharf.*

Construction works associated with the upgrade of Combwich Wharf will be relatively short-term and therefore the standard approach to the designation of construction noise limits has been used, allowing for short-term noisy events within a given period. Given the proximity of residential dwellings to the wharf, significant noise levels are unavoidable during certain activities (notably piling). By adopting noise threshold values averaged over a longer period, other noise impact controls can be utilised, such as managing the duration of very noisy activities within each working day.

Operational Noise

> *ARUP: The presentation states that a number of issues were discussed and agreed with WSC and SDC on 9 December 2008. One of these issues was that "Industrial noise impact assessment should take account of the guidance in BS4142: 1997."*
>
> *The operational noise section states that BS4142: 1997 has not been used on the basis that it is not applicable due to very low background noise levels.*
>
> *Whilst this is the case at two locations during the night, it is not the case during the day.*
>
> *AMEC have proposed a specific noise level threshold of 43dB$L_{Aeq,T}$ (which would give a rating level of 48dB if the noise were tonal for example). This is over 20dB higher than background noise levels in some locations.*

A full rationale should be sought as to the choice of threshold level and reasoning for not using a simplified rating level of 35dBL_{Aeq} for low noise locations, as alluded to in BS4142.

This proposed target noise level would minimise the potential for sleep disturbance in accordance with guidance provided in WHO document ‘Guidelines for Community Noise’ (1999) and British Standard BS 8233: 1999 ‘Sound insulation and noise reduction for buildings – Code of practice’, even with windows open.

The rating noise criterion of 43 dB $L_{Aeq,T}$ is derived based upon achieving an internal noise level of 30 dB $L_{Aeq,night}$ within bedrooms. The WHO Guidelines for Community Noise indicates that this represents the noise level at which it is possible to start detecting effects and below which effects can be assumed to be negligible. This is generally considered a conservative and precautionary approach to noise impact assessment. PPG 24 states that a sound reduction of 13 dB L_A is expected for a partially open window, therefore 30 + 13 = 43 dB $L_{Aeq,T}$ outside a bedroom window.

In terms of potential daytime disturbance, this criterion is 7 dB below the level at which the WHO consider to be the onset of moderate annoyance in a small minority (10 %) of the population (50 dB $L_{Aeq,16hours}$).

BS 4142:1997 does not provide guidance on the approach to calculating specific noise levels for pre-determination of potential nuisance impacts, specifically taking account of meteorological effects. Given the significant impact of meteorological conditions on noise propagation over the distances involved (greater than 1.1 km), it is proposed that the 43 dB $L_{Aeq,T}$ criterion should be met even during worst-case (downwind) conditions which are atypical of the site (northerly winds from 330˚ to 30˚ represented just 8% of the wind direction between 2004 and 2008 inc.).

We hope that the above provides sufficient clarity on the issues that have been raised. If you have further queries, please feel free to contact me.

Yours sincerely
AMEC Earth & Environmental (UK) Ltd,

Ric Cope
Principal Consultant

Dear Peter

Re: Hinkley Point C
Operational noise modelling assumptions – Attenuation due to meteorological conditions
Response to technical query from ARUP (consultation meeting on 22/02/11)

In response to a query raised by your advisors at a recent consultation meeting (22 February 2011), please find below further clarifications regarding the assumption to be made regarding the detailed operational noise prediction modelling exercise for the final DCO application for Hinkley Point C.

Background

Within the Stage 2 Consultation documentation, the noise and vibration Environmental Appraisal (chapter (Volume 2 Chapter 10) provided details of the predictive noise modelling exercise undertaken for the operational phase of Hinkley Point C nuclear power station. Appendix 10B of this outlined both the technical methodology and the assumptions used with regard to the model parameters.

In summary, the calculation methodology embedded within the model (CadnaA proprietary software) was in accordance with ISO 9613: Part 2: 1996 "Attenuation of sound during propagation outdoors" (ISO 9613-2). However, within this methodology, there are various options which permit the user to select how meteorological conditions affect noise propagation. At Stage 2, the following methodologies were adopted for assessment of noise propagation under three distinct meteorological scenarios:

1) Average wind direction: The ISO 9613-2 method for determination of C_{met} based on local meteorological conditions provides the most realistic assessment of long-term noise propagation. This uses the proportionality of long term wind parameter data.

2) Downwind propagation: This is based on the CONCAWE methodology (C_{met} was replaced by K_4 in the ISO 9613 calculation), "The propagation of noise

from petroleum and petrochemical complexes to neighbouring communities" (Report No.4/81, 1981). At Stage 2, a northerly 2.5 m/s wind was assumed.

3) Neutral: No wind directionality or speed was assumed.

Proposed Changes

- **Attenuation due to Meteorological Conditions**

The results of the operational noise modelling presented at Stage 2 indicated a significant increase in the noise level at receptor locations under the downwind scenario, using the CONCAWE method (up to + 5.2 dB change).

The CONCAWE study, now 30 years old, was based upon measurements of ambient noise levels under defined meteorological conditions, and subtraction of that measured under neutral conditions in order to derive attenuation curves (K_4) for each octave band frequency. Due to the potential variables introduced by this type of methodology, and in light of more recent published guidance (e.g. ISO 9613-2), it is not considered to be representative. Of note, ISO 9613-2 indicates that, whilst meteorological effects might fall in the range of zero to approximately +5dB (C_0), *"values in excess of 2 dB are exceptional"*.

It is therefore proposed that, rather than using the CONCAWE method to derive the effects of meteorological conditions on downwind noise levels as a worst-case scenario, a constant C_0 value of + 2dB is adopted.

Notwithstanding this, it is proposed that the assessment of impact significance will be based upon the predicted long-term noise levels (L_{AT},(LT)) using annual average meteorological conditions (C_{met}). As presented at the consultation meeting, magnitude criteria (Table 1 below) will be used to determine the significance of predicted long-term average values.

Table 1 Operational noise magnitude assessment criteria

Magnitude	**Sound pressure level (façade) under annual average wind conditions, dB L_{AT}(LT)**
High	> 40
Medium	38 - 40
Low	35 - 38
Very Low	<35

It is therefore proposed that threshold criteria for operational noise at the nearest residential dwellings is reduced from 43 dB $L_{Aeq,T}$ (proposed at Stage 2) to **38 dB $L_{Aeq,T}$ (façade)**. It is the opinion of EDF Energy that this level is reasonable and achievable.

It is assumed that the noise experienced at receptor locations will not include any distinct acoustic features, in accordance with BS4142:1997.

- **Model design and Input Data**

Since the submission of documents to the Stage 2 Consultation, there has been further work on the detailed design of Hinkley Point C. These include revisions to model input data, such as:

- plot plan, including building heights amendments;
- noise emission data, based on experience at other EDF sites;
- substation layout (National Grid design); and
- restoration topography.

These changes will alter the overall operational noise levels predicted at the sensitive receptor locations from those presented at Stage 2.

We hope that the above provides sufficient clarity on this issue. If you have any further queries, please feel free to contact me.

Yours sincerely

AMEC Earth & Environmental (UK) Ltd,

Ric Cope MIOA
Principal Consultant

cc.

APPENDIX 12A: INTRODUCTION TO AIR POLLUTION

APPENDIX 12A: INTRODUCTION TO AIR POLLUTION

12A.1.1 This appendix is designed to provide further information on the key air pollutants considered in this study.

a) Nitrogen Dioxide (NO_2) and Nitrogen Oxides (NO_x)

12A.1.2 Nitrogen dioxide (NO2) and nitric oxide (NO) are both oxides of nitrogen and together they are both referred to as NOx. All combustion processes in air produce NOx, although NO, a colourless gas, usually predominates. The conversion of NO to the red-brown gas NO2 takes place in the atmosphere via reaction with chemically active species such as ozone. It is NO2 which is associated with adverse health effects on human health. The main source of NOx in the UK is road transport.

b) Sulphur Dioxide (SO_2)

12A.1.3 Sulphur dioxide (SO2) is a gas at ambient temperature and pressure but readily dissolves in water (or rain) to give an acidic solution which is oxidised to sulphuric acid. In the UK, the predominant source of SO2 is from the combustion of sulphur containing fossil fuels, particularly coal and heavy fuel oil, and is generally a function of the sulphur content of the fuel. SO2 is an irritant when inhaled and can also lead to adverse effects on vegetation.

12A.1.4 SO2 emissions have reduced significantly in the later part of the 20th century, and are currently dominated by a relatively small number of large emitters such as coal fired power stations and refineries.

c) Particulate Matter (PM_{10} and $PM_{2.5}$)

12A.1.5 Particulate Matter is generally categorised on the basis of the size of the particles (for example $PM_{2.5}$ is particles with a diameter of less than 2.5µm). PM is made up of a wide range of materials and arises from a variety of sources. Concentrations of PM comprise primary particles emitted directly into the atmosphere from combustion sources and secondary particles formed by chemical reactions in the air. PM derives from both human-made and natural sources (such as sea spray and Saharan dust). In the UK the biggest human-made sources are stationary fuel combustion and transport.

12A.1.6 Road transport gives rise to primary particles from engine emissions, tyre and brake wear and other non-exhaust emissions. Other primary sources include quarrying, construction and non-road mobile sources. Secondary PM is formed from emissions of ammonia, sulphur dioxide and oxides of nitrogen as well as from emissions of organic compounds from both combustion sources and vegetation.

12A.1.7 Both short-term and long-term exposure to ambient levels of PM are consistently associated with respiratory and cardiovascular illness and mortality as well as other ill-health effects. The associations are believed to be causal. PM_{10} roughly equates to the mass of particles less than 10 micrometres in diameter that are likely to be inhaled into the thoracic region of the respiratory tract. Recent reviews by the World Health Organisation (WHO) and the Committee on the Medical Effects of Air

Pollutants (COMEAP) have suggested exposure to a finer fraction of particles ($PM_{2.5}$, which typically make up around two thirds of PM_{10} emissions and concentrations) give a stronger association with the observed ill-health effects, but also warn that there is evidence that the coarse fraction between ($PM_{2.5}$ - PM_{10}) also has some effects on health.

APPENDIX 12B: AIR QUALITY GUIDELINES, TARGET VALUES, STANDARDS, OBJECTIVES AND ENVIRONMENTAL ASSESSMENT LEVELS

NOT PROTECTIVELY MARKED

APPENDIX 12B AIR QUALITY GUIDELINES, TARGET VALUES, STANDARDS, OBJECTIVES AND ENVIRONMENTAL ASSESSMENT LEVELS

Table 12B.1: World Health Organisation (WHO) Air Quality Guideline (AQG) and Interim Target (IT) Values

WHO Interim Target or Guideline	Concentration Measured As	Interim Target or Guideline Value ($\mu g/m^3$)
$PM_{2.5}$		
Interim Target-1 (IT-1)	Annual mean	35
	24-hour mean (99th percentile)	75
Interim Target-2 (IT-2)	Annual mean	25
	24-hour mean (99th percentile)	50
Interim Target-3 (IT-3)	Annual mean	15
	24-hour mean (99th percentile)	37.5
Air Quality Guideline	Annual mean	10
	24-hour mean (99th percentile)	25
PM_{10}		
Interim Target-1 (IT-1)	Annual mean	70
	24-hour mean (99th percentile)	150
Interim Target-2 (IT-2)	Annual mean	50
	24-hour mean (99th percentile)	100
Interim Target-3 (IT-3)	Annual mean	30
	24-hour mean (99th percentile)	75
Air Quality Guideline	Annual mean	20
	24-hour mean (99th percentile)	50
O_3		
High Levels	Daily maximum 8-hour mean	240
Interim Target-1 (IT-1)	Daily maximum 8-hour mean	160
Air Quality Guideline	Daily maximum 8-hour mean	100
NO_2		
Air Quality Guideline	Annual mean	40
	1-hour mean	200

WHO Interim Target or Guideline	Concentration Measured As	Interim Target or Guideline Value ($\mu g/m^3$)
SO_2		
Interim Target-1 (IT-1)	24-hour mean	125
	10-minute mean	-
Interim Target-2 (IT-2)	24-hour mean	50
	10-minute mean	-
Air Quality Guideline	24-hour mean	20
	10-minute mean	500

Table 12B.2: European Union Air Quality Standards and Objectives

Pollutant	Concentration (µg/m³ unless otherwise stated)	Averaging Period	Date to be Achieved and Maintained Thereafter	Permitted Exceedences Each Year
$PM_{2.5}$	25 ***	1 year	Target value enters into force 1/1/2010. Limit value enters into force 1/1/2015.	n/a
SO_2	350	1 hour	Limit value enters into force 1/1/2005.	24
	125	24 hours	Limit value enters into force 1/1/2005.	3
NO_2	200	1 hour	Limit value enters into force 1/1/2010.	18
	40	1 year	Limit value enters into force 1/1/2010.*	n/a
PM_{10}	50	24 hours	Limit value enters into force 1/1/2005.**	35
	40	1 year	Limit value enters into force 1/1/2005. **	n/a
Lead	0.5	1 year	Limit value enters into force 1/1/2005 (or 1/1/2010 in the immediate vicinity of specific, notified industrial sources; and a 1.0 µg/m³ limit value applies from 1/1/2005 to 31/12/2009).	n/a
CO	10 mg/m³	Maximum daily 8 hour mean	Limit value enters into force 1/1/2005.	n/a
Benzene	5	1 year	Limit value enters into force 1/1/2010. **	n/a
Ozone	120	Maximum daily 8 hour mean	Target value enters into force 1/1/2010.	25 days averaged over 3 years
Arsenic	6 ng/m³	1 year	Target value enters into force 1/1/2012.	n/a

Pollutant	Concentration ($\mu g/m^3$ unless otherwise stated)	Averaging Period	Date to be Achieved and Maintained Thereafter	Permitted Exceedences Each Year
Cadmium	5 ng/m^3	1 year	Target value enters into force 1/1/2012.	n/a
Nickel	20 ng/m^3	1 year	Target value enters into force 1/1/2012.	n/a
Polycyclic Aromatic Hydrocarbons	1 ng/m^3 (expressed as concentration of Benzo(a)pyrene)	1 year	Target value enters into force 1/1/2012.	n/a

** Under the new Directive the member State can apply for an extension of up to five years (i.e. maximum up to 2015) in a specific zone. Request is subject to assessment by the Commission. In such cases within the time extension period the limit value applies at the level of the limit value + maximum margin of tolerance (48 $\mu g/m^3$ for annual NO_2 limit value).*

*** Under the new Directive the Member State can apply for an extension until three years after the date of entry into force of the new Directive (i.e. May 2011) in a specific zone. Request is subject to assessment by the Commission. In such cases within the time extension period the limit value applies at the level of the limit value + maximum margin of tolerance (35 days at 75$\mu g/m^3$ for daily PM_{10} limit value, 48 $\mu g/m^3$ for annual PM_{10} limit value).*

**** Standard introduced by the new Directive.*

Table 12B.3: National Air Quality Objectives

Pollutant	Applies	National Air Quality Objective	Concentration Measured as	Date to be Achieved by and Maintained Thereafter
For the Protection of Human Health				
Particles (PM_{10})	UK	50 µg/m^3 not to be exceeded more than 35 times a year	24 hour mean	31 December 2004
	UK	40 µg/m^3	Annual mean	31 December 2004
Particles ($PM_{2.5}$)	UK (except Scotland)	25 µg/m^3	Annual mean	1 January 2015
NO_2	UK	200 µg/m^3 not to be exceeded more than 18 times a year	1 hour mean	31 December 2005
	UK	40 µg/m^3	Annual mean	31 December 2005
O_3	UK	120 µg/m^3 not to be exceeded on more than 25 days per calendar year averaged over 3 years	Maximum daily 8 hour mean	31 December 2005
SO_2	UK	266 µg/m^3 not to be exceeded more than 35 times a year	15 minute mean	31 December 2005
	UK	350 µg/m^3 not to be exceeded more than 24 times a year	1 hour mean	31 December 2004
	UK	125 µg/m^3 not to be exceeded more than 3 times a year	24 hour mean	31 December 2004
Polycyclic aromatic hydrocarbons	UK	0.25 ng/m^3 B[a]P	As annual average	31 December 2010
Benzene	England and Wales	5 µg/m^3	Annual average	31 December 2010
1,3 Butadiene	UK	2.25 µg/m^3	Running annual mean	31 December 2003
CO	UK	10 mg/m^3	Maximum daily running 8 hour mean	31 December 2003
Lead	UK	0.5 µg/m^3	Annual mean	31 December 2004

Pollutant	Applies	National Air Quality Objective	Concentration Measured as	Date to be Achieved by and Maintained Thereafter
For the Protection of Vegetation and Ecosystems				
NO_x	UK	30 µg/m^3	Annual mean	31 December 2000
SO_2	UK	20 µg/m^3	Annual mean	31 December 2000
	UK	20 µg/m^3	Winter average	31 December 2000
Ozone	UK	Target value of 18,000 µg/m^3 based on AOT40 to be calculated from 1 hour values from May to July, and to be achieved, so far as possible, by 2010	Average over 5 years	1 January 2010

Table 12B.4: Environment Agency Environmental Assessment Levels for those Pollutants and/or Averaging Periods for which an Equivalent Air Quality Standard or Objective is not Prescribed

Pollutant	Applies	Environmental Assessment Level	Concentration measured as
For the Protection of Human Health			
NH_3	UK	180 µg/m^3	Annual mean
	UK	2,500 µg/m^3	1hour mean
H_2CO	UK	5 µg/m^3	Annual mean
	UK	100 µg/m^3	1hour mean
CO	UK	30,000 µg/m^3	1 hour mean
For the Protection of Vegetation and Ecosystems			
NO_x	UK	75 µg/m^3	Daily mean

APPENDIX 12C: AIR QUALITY SIGNIFICANCE CRITERIA

APPENDIX 12C: AIR QUALITY SIGNIFICANCE CRITERIA

Table 12C.1: Definition of Impact Magnitude for Changes in Annual Mean NO_2 and PM_{10} Concentration from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >4µg/m^3
Medium	Increase/decrease 2 - 4µg/m^3
Small	Increase/decrease 0.4 - 2µg/m^3
Imperceptible	Increase/decrease <0.4µg/m^3

Table 12C.2: Air Quality Impact Descriptors for Changes to Annual Mean NO_2 and PM_{10} from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>40µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (36 - 40µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (30 - 36µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<30µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.3: Definition of Impact Magnitude for Changes in Number of exceedences of 1-hour Mean NO_2 Concentration Greater than 200µg/m^3 for Road Traffic and On-Site Exhaust Emissions to Air from Construction Plant and Machinery.

Magnitude of Change	Number of time above 200µg/m^3 [a]
Large	Increase/decrease >2 hours
Medium	Increase/decrease 1 - 2 hours
Small	Increase/decrease 0 - 1 hour
70Imperceptible	Increase/decrease 0 hours

[a] Based on percentage of 18 exceedences, rounded to the most appropriate whole number of exceedences.

Table 12C.4: Air Quality Impact Descriptors for Changes in Number of Exceedences of 1-hour NO_2 Concentration Greater than 200µg/m^3 from Road Traffic and On-Site Exhaust Emissions to Air from Construction Plant and Machinery.

Absolute Concentration in Relation to Objective/Limit Value	Change in Number of Days [a b]		
	Small	Medium	Large
Above objective/limit value with scheme (>18 times)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (16 - 18 times)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (14 - 16 times)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<14 times)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

[b] Based on percentage of 18 allowed exceedences, rounded to the most appropriate whole number of exceedences.

Table 12C.5: Definition of Impact Magnitude for Changes in 1-hour Mean NO_2 99.79 Percentile Concentration at Human Receptor Locations from Marine Vessels and emissions from HPC Commissioning and Operation.

Magnitude of Change	1-hour Mean
Large	Increase/decrease >20 µg/m^3
Medium	Increase/decrease 10 – 20 µg/m^3
Small	Increase/decrease 2 – 10 µg/m^3
Imperceptible	Increase/decrease <2 µg/m^3

Table 12C.6: Air Quality Impact Descriptors for Changes to 1-hour Mean NO_2 99.79 Percentile Concentration at Human Receptor Locations from Marine Vessels and emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>200 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (180 - 200 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (150– 180 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<150 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.7: Definition of Impact Magnitude for Changes in Annual Mean NO_x Concentration at Ecological Receptor Locations from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >3µg/m^3
Medium	Increase/decrease 1.5 - 3µg/m^3
Small	Increase/decrease 0.3 – 1.5µg/m^3
Imperceptible	Increase/decrease <0.3µg/m^3

Table 12C.8: Air Quality Impact Descriptors for Changes to Annual Mean NO_x at Ecological Receptor Locations from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>30µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (27 - 30µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (22.5 - 27µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<22.5µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.9: Definition of Impact Magnitude for Changes in 24-hour Mean NO_x Concentration at Ecological Receptor Locations from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Magnitude of Change	24-hour Mean
Large	Increase/decrease >7.5µg/m^3
Medium	Increase/decrease 3.75 – 7.5µg/m^3
Small	Increase/decrease 0.75 – 3.75µg/m^3
Imperceptible	Increase/decrease <0.75µg/m^3

Table 12C.10: Air Quality Impact Descriptors for Changes to 24-hour Mean NOx at Ecological Receptor Locations from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>75µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (67.5 - 75µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (56.25 – 67.5µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<56.25µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.11: Definition of Impact Magnitude for Changes in 24-hour Mean PM_{10} Concentration from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from HPC Commissioning and Operation.

Magnitude of Change	24-hour Mean
Large	Increase/decrease >5µg/m^3
Medium	Increase/decrease 2.5 - 5µg/m^3
Small	Increase/decrease 0.5 – 2.5µg/m^3
Imperceptible	Increase/decrease <0.5µg/m^3

Table 12C.12: Air Quality Impact Descriptors for Changes to Annual Mean $PM_{2.5}$ from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>50µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (45 - 50µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (37.5 - 45µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<37.5µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.13: Definition of Impact Magnitude for Changes in Annual Mean $PM_{2.5}$ Concentration from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >2.5µg/m^3
Medium	Increase/decrease 1.25 - 2.5µg/m^3
Small	Increase/decrease 0.25 - 1.25µg/m^3
Imperceptible	Increase/decrease <0.25µg/m^3

Table 12C.14: Air Quality Impact Descriptors for Changes to Annual Mean $PM_{2.5}$ from Road Traffic, Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>25µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (22.5 - 25µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (18.75 - 22.5µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<18.75µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.15: Definition of Impact Magnitude for Changes in Number of Days with PM_{10} Concentration Greater than 50µg/m^3 from Road Traffic and On-Site Exhaust Emissions to Air from Construction Plant and Machinery.

Magnitude of Change	Number of days above 50µg/m^3 [a]
Large	Increase/decrease >4 days
Medium	Increase/decrease 2 - 4 days
Small	Increase/decrease 1 - 2 days
Imperceptible	Increase/decrease <1 day

[a] Based on percentage of 35 days, rounded to the most appropriate whole number of days.

Table 12C.16: Air Quality Impact Descriptors for Changes to Number of Days with PM_{10} Concentration Greater than 50µg/m^3 from Road Traffic and On-Site Exhaust Emissions to Air from Construction Plant and Machinery.

Absolute Concentration in Relation to Objective/Limit Value	Change in Number of Days [a b]		
	Small	Medium	Large
Above objective/limit value with scheme (>35 days)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (32 - 35 days)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (26 - 32 days)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<26 days)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

[b] Based on percentage of 35 days, rounded to the most appropriate whole number of days.

Table 12C.17: Definition of Impact Magnitude for Changes in Annual Mean SO_2 Concentration at Ecological Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >2 µg/m^3
Medium	Increase/decrease 1 - 2 µg/m^3
Small	Increase/decrease 0.2 - 1 µg/m^3
Imperceptible	Increase/decrease <0.2 µg/m^3

Table 12C.18: Air Quality Impact Descriptors for Changes to Annual Mean SO_2 at Ecological Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>20µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (18 - 20µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (15 - 18µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<15µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'

Table 12C.19: Definition of Impact Magnitude for Changes in 1-hour Mean SO_2 99.73 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Magnitude of Change	1-hour Mean
Large	Increase/decrease >35 µg/m^3
Medium	Increase/decrease 17.5 – 35 µg/m^3
Small	Increase/decrease 3.5 – 17.5 µg/m^3
Imperceptible	Increase/decrease <3.5 µg/m^3

Table 12C.20: Air Quality Impact Descriptors for Changes to 1-hour Mean SO_2 99.73 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>350 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (315 - 350 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (262.5 - 315 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<262.5 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.21: Definition of Impact Magnitude for Changes in 24-hour Mean SO_2 99.18 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Magnitude of Change	24-hour Mean
Large	Increase/decrease >12.5 µg/m^3
Medium	Increase/decrease 6.25 – 12.5 µg/m^3
Small	Increase/decrease 1.25 – 6.25 µg/m^3
Imperceptible	Increase/decrease <1.25 µg/m^3

Table 12C.22: Air Quality Impact Descriptors for Changes to 24-hour Mean SO_2 99.18 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>125 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (112.5 - 125 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (93.75–112.5 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<93.75 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.23: Definition of Impact Magnitude for Changes in 15-minute Mean SO_2 99.9 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant and Machinery, and from Emissions from HPC Commissioning and Operation.

Magnitude of Change	15-minute Mean
Large	Increase/decrease >26.6 µg/m^3
Medium	Increase/decrease 13.3 – 26.6 µg/m^3
Small	Increase/decrease 2.66 – 13.3 µg/m^3
Imperceptible	Increase/decrease <2.66 µg/m^3

Table 12C.24: Air Quality Impact Descriptors for Changes to 15-minute Mean SO_2 99.9 Percentile Concentration at Human Receptor Locations from Marine Vessels, On-Site Exhaust Emissions to Air from Construction Plant, and Machinery and from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>266 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (239.4 - 266 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (199.5 – 239.4 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<199.5 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.25: Definition of Impact Magnitude for Changes in 8-hour rolling Mean CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	8-hour rolling Mean
Large	Increase/decrease >1000 µg/m^3
Medium	Increase/decrease 500 – 1000 µg/m^3
Small	Increase/decrease 100 – 500 µg/m^3
Imperceptible	Increase/decrease <100 µg/m^3

Table 12C.26: Air Quality Impact Descriptors for Changes to 8-hour rolling Mean CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>10000 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (9000 - 10000 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (7500 – 9000 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<7500 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.27: Definition of Impact Magnitude for Changes in 1-hour Mean CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	1-hour Mean
Large	Increase/decrease >3000 µg/m^3
Medium	Increase/decrease 1500 – 3000 µg/m^3
Small	Increase/decrease 300 – 1500 µg/m^3
Imperceptible	Increase/decrease <300 µg/m^3

Table 12C.28: Air Quality Impact Descriptors for Changes to 1-hour rolling Mean CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>30000 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (27000 - 30000 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (22500 – 27000 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<22500 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.29: Definition of Impact Magnitude for Changes in Annual Mean H_2CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >0.5 µg/m^3
Medium	Increase/decrease 0.25 – 0.5 µg/m^3
Small	Increase/decrease 0.05– 0.25 µg/m^3
Imperceptible	Increase/decrease 0.05 µg/m^3

Table 12C.30: Air Quality Impact Descriptors for Changes to Annual Mean H_2CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>5 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (4.5 – 5 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (3.75 – 4.5 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<3.75 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as 'negligible'.

Table 12C.31: Definition of Impact Magnitude for Changes in 1-hour mean H_2CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	1-hour Mean
Large	Increase/decrease >10 µg/m^3
Medium	Increase/decrease 5 – 10 µg/m^3
Small	Increase/decrease 1 – 5 µg/m^3
Imperceptible	Increase/decrease 1 µg/m^3

Table 12C.32: Air Quality Impact Descriptors for Changes to 1-hour mean H_2CO Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>100 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (90 – 100 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (75 – 90 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<75 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.33: Definition of Impact Magnitude for Changes in Annual Mean NH_3 Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >18 µg/m^3
Medium	Increase/decrease 9 – 18 µg/m^3
Small	Increase/decrease 1.8 – 9 µg/m^3
Imperceptible	Increase/decrease 1.8 µg/m^3

Table 12C.34: Air Quality Impact Descriptors for Changes to Annual Mean NH_3 Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>180 μg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (162 – 180 μg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (135 – 162 μg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<3.75 μg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.35: Definition of Impact Magnitude for Changes in 1-hour mean NH_3 Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	1-hour Mean
Large	Increase/decrease >250 μg/m^3
Medium	Increase/decrease 125 – 250 μg/m^3
Small	Increase/decrease 12.5 – 125 μg/m^3
Imperceptible	Increase/decrease 12.5 μg/m^3

Table 12C.36: Air Quality Impact Descriptors for Changes to 1-hour mean NH_3 Concentration at Human Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>2500 μg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (2250 – 2500 μg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (1875 – 2250 μg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<1875 μg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Table 12C.37: Definition of Impact Magnitude for Changes in annual mean NH_3 Concentration at Ecological Receptor Locations from Emissions from HPC Commissioning and Operation.

Magnitude of Change	Annual Mean
Large	Increase/decrease >0.3 µg/m^3
Medium	Increase/decrease 0.15 – 0.3 µg/m^3
Small	Increase/decrease 0.03 – 0.15 µg/m^3
Imperceptible	Increase/decrease 0.03 µg/m^3

Table 12C.38: Air Quality Impact Descriptors for Changes in annual mean NH_3 Concentration at Ecological Receptor Locations from Emissions from HPC Commissioning and Operation.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration [a]		
	Small	Medium	Large
Above objective/limit value with scheme (>3 µg/m^3)	Slight adverse	Moderate adverse	Substantial adverse
Just below objective/limit value with scheme (2.7 – 3 µg/m^3)	Slight adverse	Moderate adverse	Moderate adverse
Below objective/limit value with scheme (2.25 – 2.7 µg/m^3)	Negligible	Slight adverse	Slight adverse
Well below objective/limit value with scheme (<2.25 µg/m^3)	Negligible	Negligible	Slight adverse

[a] An Imperceptible change would be described as ‘negligible’.

Thermal decomposition of insulation material - commissioning and operational phases	H_2CO	5 (annual mean)	100 (1-hour mean)	-	-
	CO	-	10000 (8-hour mean)	-	-
	CO	-	30000 (1-hour mean)	-	-

Process	Substance released to air	Human health EAL [a]		Ecological EAL [b]	
		Long-term ($\mu g/m^3$)	Short-term ($\mu g/m^3$)	Long-term ($\mu g/m^3$)	Short-term ($\mu g/m^3$)
Discharges as the temperature rises in the steam generators during start-up - operational phase	NH_3	180 (annual mean)	2500 (1-hour mean)	3 (annual mean)	-

[a] All EALs for human receptor location obtained from Table B1 and Table B5 of Environment Agency's H1 guidance - Annex (f) Air emissions (2010).
[b] All EALs for ecological receptor location obtained from Table B4 of Environment Agency's H1 guidance - Annex (f) Air emissions (2010).

Table 12D.4: Background Pollutant Concentrations used in H1 Assessment

Process	Substance released to air	Annual average background concentration for 2009 (µg/m^3)
Thermal decomposition of insulation material - commissioning phase	H_2CO [a]	0.0
	CO [b]	78.5
Exhaust gases from engines of backup diesel generators during periodic testing	SO_2 [c]	1.8
	NO_2 [d]	6.8
	NO_x [d]	11.5
	CO [b]	78.5
	PM_{10} [d]	18.2
	$PM_{2.5}$ [e]	7.9
Thermal decomposition of insulation material - plant start-up or resuming of operation following routine maintenance	H_2CO [a]	0.0
	CO [b]	78.5
Discharges as the temperature rises in the steam generators during start-up	NH_3 [f]	1.1

[a] Background concentration of formaldehyde assumed to be negligible.

[b] Background concentration of carbon monoxide taken from Defra's UK Air Quality Archive (average of the four 1km x 1km grid squares closest to Hinkley Point). 2001 background map CO annual mean concentrations factored to 2009 using published Defra annual adjustment factors.

[c] 2009 annual mean background concentration of SO2 assumed to be equal to 2008 annual mean SO2 concentration obtained from the baseline air quality monitoring campaign.

[d] 2009 annual mean background concentrations of NO2, NOx and PM10 obtained by applying the ratio for 2008 to 2009 annual mean concentrations from Defra's UK Air Quality Archive (average of the four 1km x 1km grid squares closest to Hinkley Point) to 2008 annual mean pollutant concentrations obtained from the baseline air quality monitoring campaign.

[e] 2009 annual mean background concentration of PM2.5 taken from Defra's UK Air Quality Archive (average of the four 1km x 1km grid squares closest to Hinkley Point).

[f] 2009 annual mean background concentration of NH3 assumed to be equal to 2008 annual mean concentration obtained from the Ammonia Monitoring Network results for North Wyke.

Table 12D.5: Short-term and Long-term Process Contributions to air (*PC_{air}*) Calculated by H1 Methodology for the Commissioning and Routine Test Scenarios

Substance released to air	Commissioning		Routine Test	
	Process Contribution, PC_{air} - long (µg/m^3)	Process Contribution, PC_{air} - short (µg/m^3)	Process Contribution, PC_{air} - long (µg/m^3)	Process Contribution, PC_{air} - short (µg/m^3)

Table 12D.8: Stack Parameters and Emission Rates for EDGs and SBOs and Non-diesel Generator Emissions to Air

Parameter	Value [a]	Units
EDG Emissions		
Stack internal diameter	1.0	M
Stack height	30.0	m
Exit velocity	35	m/s
Ambient temperature of discharge gases	375	˚C
SO_2 emission rate	2.93	g/s
NO_x emission rate	30.66	g/s
PM_{10} emission rate	0.80	g/s
CO emission rate	2.41	g/s
SBO Emissions		
Stack internal diameter	0.82	m
Stack height	30.0	m
Exit velocity	15.0	m/s
Ambient temperature of discharge gases	515	˚C
SO_2 emission rate	0.40	g/s
NO_x emission rate	6.80	g/s
PM_{10} emission rate	0.19	g/s
CO emission rate	0.57	g/s
Main Stack Emissions		
Stack internal diameter	3.0	m
Stack height	70.0	m
Exit velocity	0.982	m/s
Ambient temperature of discharge gases	15	˚C
H_2CO emission rate (commissioning)	0.0342	g/s
CO emission rate (commissioning)	0.0320	g/s
H_2CO emission rate (operation)	0.0243	g/s
CO emission rate (operation)	0.0229	g/s
NH_3 Emissions		
Stack internal diameter	2.66	m
Stack height	38.0	m
Exit velocity	0.53	m/s
Ambient temperature of discharge gases	100	˚C
NH_3 emission rate	3.12	g/s

[a] All input data parameters acquired from EDF 'Pre-Construction Environmental Report (PCER)' (2009), EDF Technical Note 'ECUK100656 rev B - Assumptions to be taken into account for the EIA (IPC Submission) concerning the diesels' (2011) and Flamanville 3 data provided in SR email 01/02/11.

APPENDIX 13A: AGRICULTURAL LAND CLASSIFICATION SURVEY REPORT

EDF Energy

Land at Hinkley Point, Somerset

Investigation of Soils and Agricultural Land Classification

Reading Agricultural Consultants

June 2009

1. Introduction

1.1 Instruction

1.1.1 Reading Agricultural Consultants Ltd (RAC) is instructed by EDF Energy to investigate the Agricultural Land Classification (ALC) of an area to the west of Hinkley Point power station in Somerset. This investigation has been conducted by a combination of detailed field investigation and a comprehensive review of previous surveys in the area.

1.1.2 The first ALC survey of parts of the site that has been identified was a 1982 study by ADAS for the Ministry of Agriculture Fisheries and Food (MAFF). This was followed by an ALC survey by RAC in 1988 which was supplemented by further soil resource surveys later in the same year. The present-day site boundary is a little different to that used in the previous RAC studies and therefore supplementary fieldwork has been carried out in 2009 to cover the new ground and to check the previous work against revisions to the ALC classification system.

2. Site and Climatic Characteristics

2.1 General features, Land Form and Drainage

2.1.1 The total area considered is about 84 ha, the boundary being shown in red on Figure RAC 1. The land is bounded principally by other agricultural land, but has a power station to the east and Bridgwater Bay to the north. Existing use of the agricultural land is largely arable, without irrigation, and the land was mostly under field crops at the time of survey. There are several agricultural buildings within the site boundary, but they appear to be mainly derelict.

2.1.2 The land forms an undulating plain over the most part, with an overall fall to the north. There is a series of parallel east-west ridges with a south-facing scarp face as the southern boundary. Slopes are convexo-concave, sometimes with a pronounced midslope rectilinear element. The altitude of most of the site falls between about 9 and 35 m aOD. Microtopography is usually smooth to gently undulating. The soils have generally good drainage being of wetness class (WC) WC**I**, but with some areas of imperfect drainage (WC**III**) where there is underlying clay.

2.2 Climatic Factors

2.2.1 Local climatic factors have been interpolated from the Meteorological Office's standard 5 km grid point data set for the centre of the site at a representative altitude. Climatic factors are given in Table 1. The local climate has slightly higher rainfall than is typical for lowland England and the area can be considered moist. Temperatures are warm. The moisture deficits are moderate to moderately large. The FCD regime is slightly longer than the average for lowland England and can be considered to be slightly unfavourable for providing opportunities for landworks. In summary the climate is warm and moist.

Table 1: Local climatic factors

Average annual rainfall (AAR)	771 mm
Accumulated temperature > 0°C (AT0)	1,547 day°
Field Capacity Day regime (FCD)	167 days
Average moisture deficit, wheat (MDw)	105 mm
Average moisture deficit, potatoes (MDp)	98 mm

2.3 Soil Parent Materials and Soil Types

2.3.1 Hinkley Point lies on the southern margin of the Bristol Channel sedimentary basin. The basin is formed from a synclinal trough filled with sediments of Devonian to Jurassic age. West of the site area, Mesozoic rocks of Jurassic and Triassic age are exposed along the cliff line towards Watchet, whilst to the east of the site the Lower Lias cliff line gives way to the flat low-lying ground of the River Parrett estuary which forms an extensive area of Quaternary sedimentation known as the Somerset Levels.

2.3.2 The geological sequence beneath the overlying soils of the site consists of interbedded mudstones and thin limestones of the Lower Lias and Langport Formation, extending downwards into the Mercia Mudstone Group consisting of siltstones and mudstones. Figure RAC2 illustrates schematically, in block diagram form, the ground surface features and the sub-surface geology of the site area. The geology of the site is essentially that of a block of rock strata gently dipping to the north

2.3.3 The soil parent material is interbedded mudstones, siltstones and limestones. The mudstone and siltstone give soils with clayey poorly permeable subsoils whilst the limestone gives soils which are shallow over rock and stony.

2.3.4 The soils of the site have been mapped at a scale of 1” to the mile by the Soil Survey of England and Wales, and described in the memoir “The Soils of the Mendip District of Somerset” by D C Findlay, 1965. This scale was not sufficiently detailed to allow clear separation of the soil types present and the whole site was mapped as having soils of the Evesham series, which are imperfectly drained calcareous soils with poorly permeable subsoil.

2.3.5 All the soils are calcareous and are slightly alkaline. The topsoils are of clay loam to clay and are usually about 250-300mm thick. Subsoils vary according to the underlying geology being poorly permeable and clayey over mudstone, but generally appear to be somewhat permeable or freely permeable over other rock types. Limestone bands are associated with shallow stony soils, particularly on the higher parts of the site.

3. Agricultural Land Quality

3.1 Soil Survey Methods

3.1.1 The preliminary RAC soil survey was carried out in late July 1988, followed by further, more detailed work in mid-August. The survey was carried out using hand auger and spade, much in the manner of the 2009 fieldwork described below. In all some 102 observations were made giving a survey intensity of about 1.3 observations per hectare. The location of observations is given on Figure RAC4. The interpretation of the findings was made difficult by the impending introduction on 1 January 1989 by MAFF of revised and more detailed criteria for assessing land quality. The classification was therefore made according to the published draft of the forthcoming revised guidelines, and has been checked against the later guidelines as part of this study.

3.1.2 The additional fieldwork carried out in 2009 consisted of some twenty one soil profiles which were examined using an Edelman (Dutch) auger and spade. The location of observations is also indicated on Figure RAC4. Observation density on the newly surveyed areas of agricultural land is about 1 site per ha, and the overall survey intensity is about 1.5 per hectare with the inclusion of the 1988 observations. At each observation point the following characteristics were assessed for each soil horizon up to a maximum of 120 cm or any impenetrable layer: soil texture; significant stoniness; colour (including local gley and mottle colours); consistency; structural condition; free carbonate; and depth.

3.1.3 Soil Wetness Class (WC) was inferred from the matrix colour, presence or absence of, and depth to, greyish and ochreous gley mottling and/or poorly permeable subsoil layers at least 15 cm thick.

3.1.4 Soil droughtiness was investigated by the calculation of moisture balance equations. Crop-adjusted Available Profile Water (AP) is estimated from texture, stoniness and depth, and then compared to a calculated moisture deficit (MD) for the standard crops, wheat and potatoes. The MD is a function of potential evapotranspiration and rainfall. Grading of the land can be affected if the AP is insufficient to balance the MD. When a profile is found with significant stoniness, sufficient to prevent penetration of a hand auger, then it is assumed, for the purposes of calculating droughtiness, that similar levels of stoniness continues to the full 1.2 m depth considered.

3.1.5 Four soil samples were subject to laboratory determination of particle size analysis, pH and the nutrients phosphorous, potassium, and magnesium. Results are given in Appendix 1.

3.2 Previous Survey Results

3.2.1 An ALC survey covering a portion of the site was carried out by MAFF in 1982, and is reproduced as Figure RAC3 with the current survey boundary overlain. This 1982 survey was made according to the ALC system prevalent at the time which had three divisions to Grade 3. The predominant land classification on the 1982 map is Subgrade 3c, which is low medium quality agricultural land.

3.2.2 The 1988 RAC ALC survey covered most of the present day site and showed the site to be principally Subgrade 3b, which is moderate quality agricultural land. The Subgrade 3c was removed from the ALC system with the 1988 revision, though there were so many fundamental differences introduced then that there is no direct or close parity between similarly named units mapped before and after 1988. A band of Subgrade 3a, good quality agricultural land, crosses the site over the southern half.

3.3 ALC and Main Limitations on the Agricultural Land

3.3.1 The principal constraints to agriculture are:

- seasonal soil wetness; from soil profile impermeability and the presence of heavy-textured impermeable layers in soil profiles, exacerbated by the slightly longer than average field capacity period of 167 days in this district in an average year, which combine to limit soil workability and the opportunity days for landworks;

- superficial stoniness, often associated with shallow soil depth, which makes cultivation, seed-bed preparation and seed sowing difficult;

- locally steep gradient, often associated with an uneven land form in some fields and occasional rock outcrops, which hinder cultivations;

- exposure to strong winds, sometimes salt-laden, which may damage crops.

3.3.2 Overall, these factors generally restrict the range of arable cropping to autumn-sown cereal and oilseed rape crops, or grass which is restricted considerably in its use by grazing livestock. The timing of cultivations and other landwork, as well as carefully controlled access for livestock, is especially important for successful farming and satisfactory crop yields. The limitation is usually to Subgrade 3b, moderate quality land, but where conditions are slightly more favourable the limitation is to Subgrade 3a, good quality land.

3.3.3 Across the southernmost part of the site, which is a steep south-facing scarp, gradients in excess of 7° limit the land quality to no better than Subgrade 3b, and gradients in excess of 11°, but less than 18°, limit the land quality to no better than Grade 4. The downgrading is based on the hazardous nature of operating agricultural equipment on steep slopes.

3.3.4 The areas of the various ALC grades are given in Table 2 and are mapped on Figure RAC5, which is a combination of the 1988 survey results supplemented by the 2009 survey. Approximately 70% of the site is classified as moderate quality agricultural land (Subgrade 3b), with Subgrade 3a land (which falls within the category of the 'best and most versatile land (Grades 1, 2, and 3a)) accounting for 24% of the agricultural land on the site. The remaining 6% is poor quality Grade 4 land.

Table 2: ALC Areas

Grade	Description	Area (ha)	Area (% of agric. land)
Subgrade 3a	Good quality	19.5	24
Subgrade 3b	Moderate quality	57.0	70
Grade 4	Poor quality	5.5	6
Total agricultural		82.0	100
	Best and most versatile	19.5	24
Non agricultural		2.0	
Total Area		84.0

EDF Energy

Land at Hinkley Point, Somerset

Investigation of Soils and Agricultural Land Classification

Reading Agricultural Consultants

May 2010

1. Introduction

1.1 Instruction

1.1.1 Reading Agricultural Consultants Ltd (RAC) is instructed by EDF Energy to investigate the Agricultural Land Classification (ALC) of an area to the west of Hinkley Point power station in Somerset. This investigation has been conducted by a combination of detailed field investigation and a comprehensive review of previous surveys in the area.

1.1.2 The first ALC survey of parts of the site that has been identified was a 1982 study by ADAS for the Ministry of Agriculture Fisheries and Food (MAFF). This was followed by an ALC survey by RAC in 1988 which was supplemented by further soil resource surveys later in the same year.

1.1.3 In 2009, a larger ALC survey was carried out that included land to the west and south of the 1988 survey. This covered new ground and checked the previous work against revisions to the ALC classification system.

1.1.4 The present-day site boundary incorporates land to the south of the 2009 survey and therefore supplementary fieldwork has been carried out in 2010 to cover the new ground and build upon the findings of the previous surveys.

2. Site and Climatic Characteristics

2.1 General features, Land Form and Drainage

2.1.1 The total area considered is about 171 ha, the boundary being shown in red on Figure RAC4547-1. The land is bounded principally by other agricultural land, but has a power station to the east and Bridgwater Bay to the north. There are some residential developments close to the southern site border.

2.1.2 Existing use of the agricultural land is largely arable, without irrigation, and the land was mostly under field crops at the time of survey. There are several agricultural buildings within the northern half of the site, but they appear to be mainly derelict.

2.1.3 The site is divided centrally by a valley running east to west with land to the north and south consisting of broad interfluves.

2.1.4 Land to the north of the valley forms an undulating plain over the most part, with an overall fall to the north. There is a series of parallel east-west ridges with a south-facing scarp face forming the northern side of the valley. Slopes are convexo-concave, sometimes with a pronounced midslope rectilinear element.

2.1.5 The land to the south of the valley forms a broad flat top ridge over the most part. Gentle slopes are present towards the southern boundary where another valley system is present along and to the south of the southern boundary. Gradients increase in steepness with proximity to the central valley, but level off within the valley to give a relatively broad flat valley bottom.

2.1.6 The altitude of most of the site falls between about 5 and 35 m aOD. Microtopography is usually smooth to gently undulating. The northern soils have generally good drainage being of wetness class (WC) WCI, but with some areas of imperfect drainage (WCIII) where there is underlying clay. The southern soils mainly lie on the valley interfluve and exhibit variable wetness characteristics ranging from moderately well to imperfectly drained (WC II-III). The valley bottom soils are affected by a high water table and act as a receiving site for local rainfall. As such, the soils are poorly drained being of wetness class (WC) IV.

2.2 Climatic Factors

2.2.1 Local climatic factors have been interpolated from the Meteorological Office's standard 5 km grid point data set for the centre of the site at a representative altitude. Climatic factors are given in Table 1. The local climate has slightly higher rainfall than is typical for lowland England and the area can be considered moist. Temperatures are warm. The moisture deficits are moderate to moderately large. The Field Capacity Day (FCD) regime is slightly longer than the average for lowland England and can be considered to be slightly unfavourable for providing opportunities for landworks. In summary the climate is warm and moist.

Table 1: Local climatic factors

Average annual rainfall (AAR)	771 mm
Accumulated temperature > 0°C (AT0)	1,547 day°
Field Capacity Day regime (FCD)	167 days
Average moisture deficit, wheat (MDw)	105 mm
Average moisture deficit, potatoes (MDp)	98 mm

2.3 Soil Parent Materials and Soil Types

2.3.1 Hinkley Point lies on the southern margin of the Bristol Channel sedimentary basin. The basin is formed from a synclinal trough filled with sediments of Devonian to Jurassic age. West of the site area, Mesozoic rocks of Jurassic and Triassic age are exposed along the cliff line towards Watchet, whilst to the east of the site the Lower Lias cliff line gives way to the flat low-lying ground of the River Parrett estuary which forms an extensive area of Quaternary sedimentation known as the Somerset Levels.

2.3.2 The geological sequence beneath the overlying soils of much of the site consists of interbedded mudstones and thin limestones of the Lower Lias and Langport Formation, extending downwards into the Mercia Mudstone Group consisting of siltstones and mudstones. Where depressed areas are present, superficial alluvial deposits become the dominant soil parent material. Figure RAC4547-2 illustrates schematically, in block diagram form, the ground surface features and the sub-surface geology of the northern area.

2.3.3 The soils of the site have been mapped at a scale of 1" to one mile by the Soil Survey of England and Wales, and described in the memoir "The Soils of the Mendip District of Somerset" by D C Findlay, 1965. This map shows four principal soil types as being present at this site, with the majority of the higher interfluve land having soils of the Evesham series, which are imperfectly drained calcareous soils with poorly permeable subsoil.

2.3.4 The central valley system largely consists of soils of the Butleigh series. These soils are formed over fine textured alluvium and colluvium derived from the calcareous shales and clays of the Lower Lias. They are clayey and often found on flat or gently sloping land which receives drainage from adjoining high ground in the winter. The internal drainage is slow and soils may be affected by a fluctuating water table.

2.3.5 Further west and on the north side of the central valley the Butleigh soils give way to a small area of Worcester series soil. These soils are derived from Keuper Marl and typically consist of clay loam over stoneless clay with a characteristic reddish colour. Gleying features can be obscured by the dusky red hue but the abundance of concretionary manganiferous deposits indicates some drainage impedance.

2.3.6 A thin strip of Compton series soils runs along the southern boundary where the land begins to slope gently into a depressed area located off site. These soils are developed on extensive tracts of alluvium and colluviums derived from the Keuper Marl. They are typically clayey with drainage ranging from imperfect to poor, depending on the thickness of alluvium and the depth to the permanent water table. Surface layers may suffer temporary waterlogging due to slow percolation but prolonged flooding is rare. However, the small area of the site mapped as having these soils proved to have shallow stony soils probably derived from gravelly Head. These soils are probably of the Huntsworth series, and are formed from Head over Lias clay, are relatively free draining and do not contain much clay or stone derived from the underlying Lias.

2.3.7 In summary, the majority of the soils consist of well structured clay topsoils with moderately structured clay upper subsoils and weakly structured calcareous clay lower subsoils that constitute a poorly permeable layer. Soils are shallower over rock on the shoulders of the slopes where there is a pronounced change in slope angle. Wet alluvial heavy clay bottom soils are present alongside the stream in the valley with well structured, organic-rich topsoil over poorly permeable heavy clay subsoil.

3. Agricultural Land Quality

3.1 Soil Survey Methods

3.1.1 The preliminary RAC soil survey was carried out in late July 1988, followed by further, more detailed work in mid-August. The survey was carried out using hand auger and spade, much in the manner of the 2009 and 2010 fieldwork described below. Some 102 observations were made in the northern part of the current site, giving a survey intensity of about 1.3 observations per hectare. The location of observations is given on Figure RAC4547-1. The interpretation of the findings of the original 1988 surveys was made in accordance with the then impending introduction in January 1989 by MAFF of revised and more detailed criteria for assessing agricultural land quality. The classification was therefore made according to the published draft of the forthcoming revised guidelines, and has been checked against the later guidelines as part of the later study.

3.1.2 Further fieldwork carried out in 2009 consisted of some twenty one soil profiles which were examined using an Edelman (Dutch) auger and spade. The location of observations is also indicated on Figure RAC4547-1. Observation density on the surveyed areas of agricultural land was about one site per ha.

3.1.3 The most recent fieldwork was carried out in February 2010 and included examination of 64 profiles. The location of the new observations is also indicated on Figure RAC4547-1. Observation density on the newly surveyed area is about one site per ha, and the overall survey intensity is about 1.1 per hectare with the inclusion of the 1988 and 2009 observations.

3.1.4 At each observation point the following characteristics were assessed for each soil horizon up to a maximum of 120 cm or any impenetrable layer: soil texture; significant stoniness; colour (including local gley and mottle colours); consistency; structural condition; free carbonate; and depth. Extensive use was made of archaeological trenches, which were open at the time of survey, and which allowed many observations to be made of soil structural characteristics.

3.1.5 Soil Wetness Class (WC) was inferred from the matrix colour, presence or absence of, and depth to, greyish and ochreous gley mottling and/or poorly permeable subsoil layers at least 15 cm thick.

3.1.6 Soil droughtiness was investigated by the calculation of moisture balance equations. Crop-adjusted Available Profile Water (AP) is estimated from texture, stoniness and depth, and then compared to a calculated moisture deficit (MD) for the standard crops, wheat and potatoes. The MD is a function of potential evapotranspiration and rainfall. Grading of the land can be affected if the AP is insufficient to balance the MD. When a profile is found with significant stoniness, sufficient to prevent penetration of a hand auger, then it is assumed, for the purposes of calculating droughtiness, that similar levels of stoniness continues to the full 1.2 m depth considered.

3.1.7 Eight soil samples were subject to laboratory determination of particle size analysis, pH and the nutrients, phosphorous, potassium and magnesium. The samples collected in 2010 were also analysed for organic matter content using the Walkley-Black method. Results are given in Appendix 1.

3.2 Previous Survey Results

3.2.1 An ALC survey covering a portion of the site was carried out by MAFF in 1982. This survey was made according to the ALC system prevalent at the time which had three subdivisions to Grade 3. The predominant land classification on the 1982 map is Subgrade 3c, which is low medium quality agricultural land.

3.2.2 The 1988 RAC ALC survey covered most of the northern half of the current site and showed the site to be principally Subgrade 3b, which is moderate quality agricultural land. The Subgrade 3c was removed from the ALC system with the 1988 revision, though there were so many fundamental differences introduced then that there is no direct or close parity between similarly named units mapped before and after 1988. A band of Subgrade 3a, good quality agricultural land, crosses the site.

3.3 ALC and Main Limitations on the Agricultural Land

3.3.1 The principal constraints to agriculture are:

- seasonal soil wetness; from soil profile impermeability and the presence of heavy-textured impermeable layers in soil profiles, exacerbated by the slightly longer than average field capacity period of 167 days in this district in an average year, which combine to limit soil workability and the opportunity days for landworks;

- superficial stoniness, often associated with shallow soil depth, which makes cultivation, seed-bed preparation and seed sowing difficult;

- locally steep gradient, often associated with an uneven land form in some fields and occasional rock outcrops, which hinder cultivations;

- cumulative wetness in the central valley, which is a receiving site, causes prolonged wetness and seriously limits soil workability and the opportunity days for landworks;

- exposure to strong winds, sometimes salt-laden, which may damage crops.

3.3.2 Overall, these factors generally restrict the range of arable cropping to autumn-sown cereal and oilseed rape crops, or grass which is restricted considerably in its use by grazing livestock. The timing of cultivations and other landwork, as well as carefully controlled access for livestock, is especially important for successful farming and satisfactory crop yields. The limitation is usually to Subgrade 3b, moderate quality land, but where conditions are slightly more favourable the limitation is to Subgrade 3a, good quality land.

3.3.3 The steep south-facing scarp slope to the north of the central valley has gradients in excess of 7° which limit the land quality to no better than Subgrade 3b, and gradients in excess of 11°, but less than 18°, limit the land quality to no better than Grade 4. The downgrading is based on the hazardous nature of operating agricultural equipment on steep slopes.

3.3.4 Within the central valley the soil wetness is considered to be severe and, in combination with the heavy clay texture, limits land to no better than Grade 4.

3.3.5 The areas of the various ALC grades are given in Table 2 and are mapped on Figure RAC4547-3, which is a combination of the 1988 survey results supplemented by the 2009 and 2010 surveys. Approximately 73% of the site is classified as moderate quality agricultural land (Subgrade 3b), with Subgrade 3a land (which falls within the category of the ‘best and most versatile land (Grades 1, 2, and 3a)) accounting for 14% of the agricultural land on the site. The remaining 13% is poor quality Grade 4 land.

Table 2: ALC Areas

Grade	Description	Area (ha)	Area (% of agric. land)
Subgrade 3a	Good quality	19.8	14
Subgrade 3b	Moderate quality	102.6	73
Grade 4	Poor quality	18.8	13
Total agricultural		141.2	100
	Best and most versatile	19.8	14
Non agricultural		30.2	
Total Area		171.4	

4. Soil Resources

4.1 Introduction

4.1.1 The soils over the area surveyed comprise topsoil over subsoil. The latter is further divided into upper and lower subsoil layers on the attached plans, principally according to its physical characteristics.

4.1.2 In this description a soil profile is arbitrarily defined as the upper 1.2 metres of the land surface.

4.1.3 Woodland soils (labelled W on figures RAC4547-4 to RAC4547-6) will be similar in their texture and layer thicknesses to the adjacent agricultural land, but their nutrient status and pH may be different. They will also have a seed store of woodland species. These factors will make them not well suited for re-use on agricultural land, but they will have qualities which will be preferred for soils used to establish new woodland or hedgerows.

4.1.4 The land in the north-east quadrant of the site, which is non-agricultural, has been considerably disturbed since the 1982 ALC survey which indicated it was agricultural land. The site has been used for tipping and disposal of waste, as well as construction of car parks and office space. Due to the potential for contamination the soils of this quadrant are not considered to be part of the soil resources of the site. However, there may be potential to utilise some soils from the wooded areas which appear to have been largely undisturbed.

4.2 Topsoil

4.2.1 Topsoils are generally of clay or heavy clay loam texture and slightly stony. Moderately stony topsoil (about 15-20% stones by volume) occurs mainly on the higher ground near Beachborough Barn and near the southern boundary of the south-westernmost field in the northern half of the site. On the southern half of the site soils are shallow over rock where there are pronounced changes in slope angle, though topsoils are usually only slightly stony.

4.2.2 Plan RAC4547-4 shows topsoil types and thicknesses. Most of the topsoil is well suited for re-use and about 250mm thick on the main agricultural areas.

4.2.3 Moderately stony topsoil (A’ on Plan 4547-4) should be stripped, stored and re-used separately from other topsoil.

4.2.4 Heavy clay topsoil of the valley bottom is not well-suited for re-use and should also be stripped, stored and re-used separately from other topsoil. The very wet nature of this part of the site may well lead to problems with soil handling.

4.3 Upper Subsoil

4.3.1 Three main types are identified, A, B and C. Plan RAC4537-5 indicates their distribution. Type A is better quality soil which should be stripped, stored and re-used separately from other upper subsoil, and be used to restore better quality agricultural land. It is slightly stony clay or silty clay loam, sometimes calcareous, and with an average thickness of 200mm to 250mm, generally being slightly thicker on the southern half of the site. It is well suited for re-use as upper subsoil on better quality agricultural restoration. At the west end and on the north side of the central valley the soil is reddish, and this should be stripped, stored and utilised separately from the other upper subsoils.

4.3.2 Type B upper subsoil is moderately well structured and generally represents the soil layer immediately above a poorly permeable clay layer. As such it is of superior quality to the under-lying lower subsoil and generally consists of slightly stony non-calcareous clay. It is generally about 150-250 mm thick. In places, mainly on higher ground but along mid-slope contours elsewhere, it can be calcareous and often overlies fractured limestone. Though only of moderate quality this soil type is the predominant upper subsoil across the site. In places there is no recoverable Type B upper subsoil indicated on Figure RAC4547-5, this is generally due to their either being rock or stones present directly under the topsoil.

4.3.3 Type C upper subsoil is heavy clay alluvium in the valley bottom, is grey and mottled, and only weakly structured. It will have low potential for re-use in any agricultural restoration and will have to be stripped, stored and re-used separately from other upper subsoil. The severe wetness of this part of the site may preclude its recovery. Thickness varies around 250mm.

4.4 Lower Subsoil

4.4.1 Three main types are identified A, B and C. Plan RAC4547-6 illustrates their distribution and thicknesses. Each type identified should be stripped, stored and re-used separately as far as possible.

4.4.2 The better quality lower subsoil (Type A) is not extensive but is similar to Type A upper subsoil and has a working thickness of up to 700mm, but may be limited in thickness by underlying stones or rock. It is well suited for re-use as subsoil, either upper or lower in replaced soil profiles, preferably in association with Type A upper subsoil and topsoil. At the west end and on the north side of the central valley the soil is reddish, and this should be stripped, stored and utilised separately from the other lower subsoils.

4.4.3 The moderate quality lower subsoil (Type B on Plan RAC4547-6) is generally poorly permeable, slightly calcareous clay over the southern half of the site and variably calcareous clay over the northern half. It has a working thickness of up to 700mm, but may be limited in thickness by underlying stones or rock. On the higher ground, limestone bands are common inclusions and these also occur unpredictably on valley sides, probably following contours. This clay is of low permeability and will impede soil drainage. It should therefore only be used in low to moderate quality agricultural restoration, and only be utilised at the base of the profile.

4.4.4 The remaining lower subsoil material (Type C) is of heavy clay texture and is very wet and impermeable. It is normally stoneless and non-calcareous on the bottom of the central valley footslopes and floors. This material is poorly suited to re-use as lower subsoil and there may well be severe difficulties in recovering the resource due to site wetness.

4.4.5 In places there is no recoverable lower subsoil indicated on Figure RAC4547-6; this is generally due to there either being rock or stones present directly under the topsoil or upper subsoil.

Appendix 2: Description of the grades, subgrades, and wetness classes (After MAFF 1988)

The ALC grades and subgrades are described below in terms of the types of limitation which can occur, typical cropping range and the expected level and consistency of yield. In practice, the grades are defined by reference to physical characteristics and the grading guidance and cut-offs for limitation factors in Section 3 enable land to be ranked in accordance with these general descriptions. The most productive and flexible land falls into Grades 1 and 2 and Subgrade 3a and collectively comprises about one-third of the agricultural land in England and Wales. About half the land is of moderate quality in Sub grade 3b or poor quality in Grade 4. Although less significant on a national scale such land can be locally valuable to agriculture and the rural economy where poorer farmland predominates. The remainder is very poor quality land in Grade 5, which mostly occurs in the uplands.

Descriptions are also given of other land categories which may be used on ALC maps.

Grade 1 -excellent quality agricultural land

Land with no or very minor limitations to agricultural use. A very wide range of agricultural and horticultural crops can be grown and commonly includes top fruit, soft fruit, salad crops and winter harvested vegetables. Yields are high and less variable than on land of lower quality.

Grade 2 -very good quality agricultural land

Land with minor limitations which affect crop yield, cultivations or harvesting. A wide range of agricultural and horticultural crops can usually be grown but on some land in the grade there may be reduced flexibility due to difficulties with the production of the more demanding crops such as winter harvested vegetables and arable root crops. The level of yield is generally high but may be lower or more variable than Grade 1.

Grade 3 --good to moderate quality agricultural land

Land with moderate limitations which affect the choice of crops, timing and type of cultivation, harvesting or the level of yield. Where more demanding crops are grown yields are generally lower or more variable than on land in Grades 1 and 2.

Subgrade 3a -good quality agricultural land

Land capable of consistently producing moderate to high yields of a narrow range of arable crops, especially cereals, or moderate yields of a wide range of crops including cereals, grass, oilseed rape, potatoes, sugar beet and the less demanding horticultural crops.

Subgrade 3b -moderate quality agricultural land

Land capable of producing moderate yields of a narrow range of crops, principally cereals and grass or lower yields of a wider range of crops or high yields of grass which can be grazed or harvested over most of the year.

Grade 4 -poor quality agricultural land

Land with severe limitations which significantly restrict the range of crops and/or level of yields. It is mainly suited to grass with occasional arable crops (e.g. cereals and forage crops) the yields of which are variable. In moist climates, yields of grass may be moderate to high but there may be difficulties in utilisation. The grade also includes very droughty arable land.

Grade 5 -very poor quality agricultural land

Land with very severe limitations which restrict use to permanent pasture or rough grazing, except for occasional pioneer forage crops.

Table 11 Definition of Soil Wetness Classes

Wetness Class	Duration of Waterlogging [1]
I	The soil profile is not wet within 70 cm depth for more than 30 days in most years[2].
II	The soil profile is wet within 70 cm depth for 31-90 days in most years *or,* if there is no slowly permeable layer within 80 cm depth, it is wet within 70 cm for more than 90 days, but not wet within 40 cm depth for more than 30 days in most years.
III	The soil profile is wet within 70 cm depth for 91-180 days in most years *or,* if there is no slowly permeable layer within 80 cm depth, it is wet within 70 cm for more than 180 days, but only wet within 40 cm depth for between 31 and 90 days in most years.
IV	The soil profile is wet within 70 cm depth for more than 180 days but not within 40 cm depth for more than 210 days in most years *or,* if there is no slowly permeable layer within 80 cm depth, it is wet within 40 cm depth for 91-210 days in most years.

V	The soil profile is wet within 40 cm depth for 211- 335 days in most years.
VI	The soil profile is wet within 40 cm depth for more than 335 days in most years.

[1] The number of days specified is not necessarily a continuous period.

[2] 'In most years' is defined as more than 10 out of 20 years.

Soils can be allocated to a wetness class on the basis of quantitative data recorded over a period of many years or by the interpretation of soil profile characteristics, site and climatic factors. Adequate quantitative data will rarely be available for ALC surveys and therefore the interpretative method of field assessment is used to identify soil wetness class in the field. The method adopted here is common to ADAS and the SSLRC.

APPENDIX 13B: SOIL WETNESS CLASSIFICATION

APPENDIX 13B: SOIL WETNESS CLASSIFICATION

13B.1.1 Soil wetness is classified according to the depth and duration of waterlogging in the soil profile. Six revised soil wetness classes (MAFF, 1988 (Ref. 13.24)) are identified and are defined below.

Table 13B.1: Definition of Soil Wetness Classes

Wetness Class	Duration of Waterlogging[1]
I	The soil profile is not wet within 70cm depth for more than 30 days in most years[2].
II	The soil profile is wet within 70cm depth for 31-90 days in most years *or,* if there is no slowly permeable layer within 80cm depth, it is wet within 70cm for more than 90 days, but not wet within 40cm depth for more than 30 days in most years.
III	The soil profile is wet within 70cm depth for 91-180 days in most years *or,* if there is no slowly permeable layer within 80cm depth, it is wet within 70cm for more than 180 days, but only wet within 40cm depth for between 31 and 90 days in most years.
IV	The soil profile is wet within 70cm depth for more than 180 days but not within 40cm depth for more than 210 days in most years *or,* if there is no slowly permeable layer within 80cm depth, it is wet within 40 cm depth for 91-210 days in most years.
V	The soil profile is wet within 40cm depth for 211–335 days in most years.
VI	The soil profile is wet within 40cm depth for more than 335 days in most years.

[1] The number of days specified is not necessarily a continuous period.

[2] 'In most years' is defined as more than 10 out of 20 years.

13B.1.2 Soils can be allocated to a wetness class on the basis of quantitative data recorded over a period of many years or by the interpretation of soil profile characteristics, site and climatic factors. Adequate quantitative data will rarely be available for ALC surveys and therefore the interpretative method of field assessment is used to identify soil wetness class in the field. The method adopted here is common to ADAS and the SSLRC.

APPENDIX 13C: AGRICULTURAL LAND CLASSIFICATION (ALC) GRADE DEFINITIONS

APPENDIX 13C: AGRICULTURAL LAND CLASSIFICATION (ALC) GRADE DEFINITIONS

13C.1.1 The ALC grades and subgrades are described below in terms of the types of limitation which can occur, typical cropping range and the expected level and consistency of yield. In practice, the grades are defined by reference to physical characteristics and the grading guidance and cut-offs for limitation factors in Section 3 enable land to be ranked in accordance with these general descriptions. The most productive and flexible land falls into Grades 1 and 2 and Subgrade 3a and collectively comprises about one-third of the agricultural land in England and Wales. About half the land is of moderate quality in Subgrade 3b or poor quality in Grade 4. Although less significant on a national scale such land can be locally valuable to agriculture and the rural economy where poorer farmland predominates. The remainder is very poor quality land in Grade 5, which mostly occurs in the uplands.

13C.1.2 Descriptions are also given of other land categories which may be used on ALC maps.

a) Grade 1 - Excellent Quality Agricultural Land

13C.1.3 Land with no or very minor limitations to agricultural use. A very wide range of agricultural and horticultural crops can be grown and commonly includes top fruit, soft fruit, salad crops and winter harvested vegetables. Yields are high and less variable than on land of lower quality.

b) Grade 2 - Very Good Quality Agricultural Land

13C.1.4 Land with minor limitations which affect crop yield, cultivations or harvesting. A wide range of agricultural and horticultural crops can usually be grown but on some land in the grade there may be reduced flexibility due to difficulties with the production of the more demanding crops such as winter harvested vegetables and arable root crops. The level of yield is generally high but may be lower or more variable than Grade 1.

c) Grade 3 – Good-to-moderate Quality Agricultural Land

13C.1.5 Land with moderate limitations which affect the choice of crops, timing and type of cultivation, harvesting or the level of yield. Where more demanding crops are grown yields are generally lower or more variable than on land in Grades 1 and 2.

i Subgrade 3a - Good Quality Agricultural Land

13C.1.6 Land capable of consistently producing moderate to high yields of a narrow range of arable crops, especially cereals, or moderate yields of a wide range of crops including cereals, grass, oilseed rape, potatoes, sugar beet and the less demanding horticultural crops.

ii Subgrade 3b - Moderate Quality Agricultural Land

13C.1.7 Land capable of producing moderate yields of a narrow range of crops, principally cereals and grass or lower yields of a wider range of crops or high yields of grass which can be grazed or harvested over most of the year.

d) Grade 4 - Poor Quality Agricultural Land

13C.1.8 Land with severe limitations which significantly restrict the range of crops and/or level of yields. It is mainly suited to grass with occasional arable crops (e.g. cereals and forage crops) the yields of which are variable. In moist climates, yields of grass may be moderate to high but there may be difficulties in utilisation. The grade also includes very droughty arable land.

e) Grade 5 - Very Poor Quality Agricultural Land

13C.1.9 Land with very severe limitations which restrict use to permanent pasture or rough grazing, except for occasional pioneer forage crops.

Date 28 July 2011

Dear Madam

ANIMAL BURIAL SITES – LAND AT HINKLEY POINT (ST202455)

I am in receipt of your faxed letter and map dated 23 July 2011 (hard copy received 28 July 2011.

The Department does not hold records of all burial sites. Burials happened many years ago when individual farmers did not need authorisation to bury animal carcases as a means of disposal.

However current records held at this office do not indicate any recent burials under our authority on land at the above location.

I enclose a map to confirm our response, but if I can be of any further assistance please contact me on 01823 348495.

Yours faithfully

Notes:

o Confidence rate in the interpretation is expressed by the way lines are drawn: the more they are dashed, the more interpretation is subject to uncertainties.
o Projected boreholes and trenches are labeled with small grey letters, whether non-projected ones are labelled with bold normal sized letters. Because of 10° northward dip of the strata, E-W-trending cross-sections are particulary influenced by projection of boreholes with signicantly different northing coordinates. This is why interpreted stratigraphical surfaces do not match precisely stratigraphical limits observed in boreholes, the shift in elevation being related to projection.
o Dip of stratigraphical limits is always represented as apparent dip. Apparent dip is written within brackets and true dip, without brackets.
o Topography has been drawn on the basis of aerial topographic survey.
o Top of W5 and W1/W0 Blue Lias have been drawn on the basis of interpolated limits whose elevation has been measured in boreholes. To obtain these interpolated surfaces, W5 or W1/W0 Blue Lias thickness has been substracted from topography.
o Strata dip is generally about N100°E 8 to 12°N (which means a slope of 14 to 21%), excluding any geological singularity. This is applicable mostly on the northern part of the site and between FT3 and FT1. In these areas, any 10 m shift towards North results in a deepening of gypsum horizons (Blue Anchor formation) of about 2 m.
The areas located between FT3 and FT2 and south of FT1 are not concerned by these considerations (poorly known geological structure).

Symbol colour indicates the nature of subcropping rock:

- Undifferenciated Blue Lias
- Buklandi
- Angulata
- Upper Liasicus
- Lower Liasicus
- Planorbis
- Lilstock formation
- Westbury formation
- Blue Anchor formation
- Red Mudstones

The small dip symbol indicates average bedding attitude from OPTV data. The figure is the dip value.
The line is the projection of the hole path in the horizontal plane (only for inclined holes).

Subcropping geology along ERT:

Undi erenciated Blue Li s

- Buklandi
- Angulata
- Upper Liasicus
- Lower Liasicus
- Planorbis
- Lilstock Fm
- Westbury Fm
- Blue Anchor Fm
- Red Mudstones

Full opacity along the layouts of cross-sections. Transparent elsewhere.

Stratification:

Trace of normal geological contact
dotted line: uncertainty about existence and/or location

11
99

Bedding attitude computed between 3 boreholes

Faulting:

Trace of main faults
dotted line: uncertainty about existence and/or location

Trace of faults
dashed line: uncertainty about location

Trace of faults
Uncertainty about existence and location

Folding:

Syncline axis
dotted line: uncertainty about existence and/or location
Only main fold axis have been drawn.

Anticline axis
dotted line: uncertainty about existence and/or location
Only main fold axis have been drawn.

Small scale folds

Electrical Resistivity Tomography profile (2010)

Cross-section layout

10 Major (thick lines with label) and minor topographic contours

Notes:

- Topographic contours are given in meters above Ordnance Datum.
- The layout of faults has been assessed through GEM2 conductivity mapping and refined with hole data.
- GEM2 depth of investigation is about 5 to 7 m belo ground level.
- The nature of the geological formation which subcrops underneath soft ground along the cross-section layout has been represented by its color (see associatd legend above).
- Geological interpretation has only been possible within the area covered by GEM2 due to a complex geological structure.

EPR UK - HINKLEY POINT
ONSHORE GEOLOGICAL, GEOTECHNICAL AND HYDRO-GEOLOGICAL INTERPRETIVE REPORT (STEP 2)

CROSS-SECTION 5

NOTES

1) Topographical contours are given in meters above Ordnance Datum (mOD).

2) The layout of the future buildings and the elevation of the formation level have been extrated from document 1512AU-030-208-GND-4018.
As the exact layout and elevation of the different buildings may change, these elements shall only be considered as indicative.
More specifically, the elevation of the formation level of some buildings is not known by CEIDRE-TEGG.

3) Geological interpretation which is shown on the map has been performed on the basis of borehole data from 1979 to 2011, 1:50 000 geological map from BGS (England and Wales sheet 279) and geophysics from 2008 to 2011. Only stratigraphical data have been used from 1979, 1984 and 1989 boreholes.

4) The exact dip of the inferred faults is not shown on the cross-section because it is difficult to assess on ERT profiles and from the complex tectonic history of the area. This is why most of them have been drawn vertical. However, many clues suggest that most of them have an important dip, typically higher than 60°.

5) Borehole logs may not match exactly the interpretated geology because they have been projected onto cross-section vertical plane. This is particularly visible for projections along E-W cross-sections because strata dip direction is roughly NNW-SSE to NNE-SSW: even a low dip (<6°) can induce a significant increase or decrease of the strata elevation.

6) Interpolation of the ammonite biozones within Blue Lias has been perfomed according to palaetonlogical data from boreholes which date from 1979 to 1989 (FEL, FESL, NWH and SML boreholes) because a dedicated study has been undertaken formerly.
Because no such study has been performed for 2008 to 2011 investigations, the base of each ammonite biozone has been drawn assuming a constant thickness for each biozone. This methodology is supported by the relative standard deviations (standard deviation versus arithmetic mean ratios) of the thickness of each biozone which are low.
Consequently, borehole logs dated from 1979 to 1989 show the measured extents of the biozones whereas borehole logs dated from 2008 to 2011 do not show the extent of the biozones.

The thicknesses which have been used to build the cross-sections are the followings:

True thickness (m)	Ammonite biozones in Blue Lias			
only on vertical boreholes	Angulata	Upper Liasicus	Lower Liasicus	Planorbis
Min	29.74	8.85	20.20	11.01
Average	30.67	9.51	21.47	12.73
Max	31.61	10.53	22.75	13.63
Standard deviation	0.93	0.40	0.84	0.42
Relative standard deviation	0.03	0.04	0.04	0.03
Chosen thickness (m)	31	10	22	13

APPENDIX 14C SUMMARY OF INTRUSIVE INVESTIGATIONS FOR THE HPC DEVELOPMENT SITE

CONTENTS

TABLES

APPENDIX 14C: SUMMARY OF INTRUSIVE INVESTIGATIONS FOR THE HPC DEVELOPMENT SITE

14C.1 Built Development Area West

14C.1.1 The Phase 1 Desk Study and Preliminary Assessment Report (Ref. 14.84) presents the findings of the non-radiological preliminary site investigation of the near surface soils (<0.3m bgl) on the Built Development Area West (BDAW). The investigation was carried out in July 2008 and comprised the excavation of 30 hand auger holes to a depth of 0.3m bgl. Samples comprised natural superficial deposits (locations are presented on **Figure 14.5**). Analytical results, details of methodology, photographic evidence and hand auger descriptions are included within the Phase 1 Desk Study report (Ref. 14.84).

14C.1.2 The Phase 2 Supplementary Investigation (Ref. 14.86) was undertaken to assess the contamination status of the deeper site soils (>0.3m bgl up to 5.0m bgl) on the BDAW and to enable further refinement of the Preliminary Conceptual Site Model (PCSM). The investigation was carried out in October 2008 and was undertaken as part of the extensive first on-shore investigation by Structural Soils Ltd. A total of 26 trial trenches were excavated to a depth of between 0.55m and 5.0m bgl across the BDAW allowing for the collection of 79 soil samples. Sampling locations are presented on **Figure 14.5**. Made Ground was encountered at one location (TRE21) extending to a depth of 0.33m bgl. In all other trenches the materials encountered predominantly comprised superficial drift deposits and weathered bedrock. Analytical results, details of methodology, photographic evidence and trial pit logs are included within the Phase 2 Supplementary Investigation report (Ref. 14.86).

14C.1.3 Limited further investigations on the BDAW were undertaken as part of the second on-shore investigation in 2010, to target historical pond features and the Made Ground encountered in the vicinity of Benhole Farm (i.e. around exploratory location TRE21). Three trial pits were excavated to a maximum depth of 5m bgl (TE82, TE83 and TE84) around TRE21. Made Ground was encountered at all three locations extending to 0.4m bgl. A further four window sample holes (WS85, WS86 and WS87) and one trial pit (TE81) were advanced to a maximum depth of 2.5m bgl and 5m bgl respectively, to target possibly infilled ponds. No Made Ground was encountered at these locations. Analytical results, details of methodology, photographic evidence and trial pit logs are included within the Phase 2 Supplementary Investigation report (Ref. 14.86).

14C.1.4 Selected soil samples collected during the investigations were analysed for a range of determinands including metals and metalloids (arsenic, cadmium, chromium, hexavalent chromium, lead, mercury, copper, nickel, zinc, selenium, water soluble boron), pH, sulphate, total cyanide sulphide, elemental sulphur, Total Petroleum Hydrocarbons (TPH C8-C35), speciated Polyaromatic Hydrocarbons (PAHs), speciated Total Petroleum Hydrocarbons (TPH), Volatile Organic Compounds (VOCs), asbestos and soil organic matter (SOM).

14C.1.5 A preliminary (Tier 1) risk assessment has been undertaken in which the chemical testing data were compared to generic human health, phytotoxic, ecotoxic and built environment SSVs. The results have been divided into natural soils and Made Ground. The results are summarised in **Table 14C.1** and **Table 14C.3**, respectively. A summary of the ecological risk assessments comparing the results to the Stage 1 ecological SSVs and Stage 2 English background soil concentrations, where necessary, are presented in **Table 14C.2** and **Table 14C.4**.

14C.1.6 Where appropriate, the analytical results were subject to further statistical tests, using the statistical approach recommended by CL:AIRE/CIEH ‘Guidance on Comparing Soil Contamination Data with a Critical Concentration) (Ref. 14.71). The 95th Upper Confidence Level (UCL) of the true population mean for each contaminant has been compared to the Critical Concentrations (Tier 1 SSV) to determine whether the site soils contain a potential source of contaminant which may pose an unacceptable risk. For the purpose of the statistical analysis all the BDAW data for natural soils samples were treated as belonging to the same ‘population’ (in statistical terms), with a second ‘population’ applied to samples taken from the Made Ground. The calculated UCLs are presented in **Table 14C.1** and **Table 14C.3**.

Table 14C.1: Summary of Chemical Analysis Results for Natural Soils on the Built Development Area West and Preliminary Tier 1 Risk Assessment

Determinand	Range of Concentrations	UCL	Tier 1 Human Health SSV	Tier 1 Phytotoxic SSV	Tier 1 Built Environment SSV (WRAS Threshold Value Unless Stated)	Exceedence of Tier 1 Human Health SSV (Number of Samples)	Exceedences of Tier 1 Phytotoxic SSV (Number of Samples)	Exceedence of Tier 1 Built Environment SSV

Soil Organic Matter	0.3-0.5	-	-	-	-	- (3)	-	-

All units mg/kg unless otherwise stated

< - Value below laboratory limit of detection

* Wessex Water revised threshold for arsenic. Wessex Water Soil Survey Guidance

FC Based on the value for Free cyanide as no total cyanide screening value exists

P Assessment of combined concentrations of both m and p isomers, based on the lower Tier 1 concentration for p xylenes.

^ In line with the Environment Agency approach in the published SGVs the GAC presented has been capped at the soil saturation limit

NC Not calculated as values below the limit of detection

~ Statistical outliers have been retained in the dataset as these values are not considered to represent a separate population

The UCL value is for deeper (>0.3m) natural soils only, retrieved during the Phase 2 Supplementary Investigation

1. Internally derived EDF Energy SSV using CLEA v1.06 using all the same standard parameters that the Environment Agency or LQM used to derive standard SGVs for commercial and industrial end use with the exception the SOM has been set to 1%
2. Defra/EA (2002). R & D Publication SGV 10. Soil Guideline Values for Lead Contamination
3. BS3882:2007 Specification for topsoil and requirements for use
4. Former ICRCL 59/83 (N.B Paper withdrawn by Defra in 2004)
5. The Hazardous Waste (England and Wales) Regulations 2005. Inert Waste Threshold

14C.2 Built Development Area East

14C.2.1 The Desk Based Assessment (Ref. 14.91) indicates that limited contamination sampling and monitoring has been conducted previously within the Built Development Area East (BDAE). A report prepared by Serco (2006) (Ref. 14.48) relates to a baseline contamination investigation for an area of land which was to be used for the temporary storage of spoil arising from the construction of a new ILW storage site for the HPA decommissioning process (i.e. the NDA temporary spoil placement area located in the north-western quadrant of the BDAE, see **Figure 14.4**). This investigation generally found low levels of soil contamination, although at two locations (H2 and BH4, see **Figure 14.7**, isolated suspected asbestos-containing materials were identified within the proposed spoil placement area. The ‘pre-closure’ report (Ref. 14.49) (i.e. a survey undertaken after the soils temporarily stored there had been removed) prepared by Serco for this area found concentrations of contaminants consistent with the baseline survey and no asbestos containing materials were identified.

14C.2.2 A number of potential sources of contamination were identified within the BDAE including a former sewage treatment works, a double-humped mound feature in the centre of the area containing surplus spoil from the construction of the existing Hinkley Point Power Station Complex, Made Ground deposits, former fabrication/construction facilities including former accommodation areas with associated boiler houses, fuel oil storage tanks and electrical substations. In addition the desk study identified the potential for radionuclide aerial deposition from the existing Hinkley Point Power Station Complex to have affected the area, with a limited potential for contaminants present in the soils and groundwater beneath the HPA and HPB to have migrated onto the BDAE.

14C.2.3 The Phase 2 Contamination Assessment (Non Radiological) of the Built Development Area East and Southern Construction Phase Area report (Ref. 14.93) presents the findings of the non-radiological investigation on the BDAE which was carried out between November 2009 and July 2010.

14C.2.4 In order to facilitate the investigation of the BDAE, the area was subdivided into six assessment areas based on current and historical land use and topography. These areas are presented on **Figure 14.4** and **Figure 14.6**. The investigations comprised the advancement of;

- 82 trial pits excavated up to between 0.5m and 5.6m bgl;
- 12 boreholes for gas monitoring purposes drilled to depths of up to 9.9m bgl (including three locations (GB21, GB3A, GB3B) which were advanced due to the required depth not being achieved at the original location), subsequently seven boreholes were installed for gas monitoring purposes;
- 18 boreholes for groundwater monitoring purposes (including CPH9 which was advanced for sampling purposes only) drilled to depths of up to 90.0m bgl;
- 20 windowless sampling holes advanced to up to 4.6m bgl; and
- eight hand pits excavated up to 1.0m bgl.

14C.2.5 The above listing includes additional exploratory hole locations advanced to delineate the presence of asbestos-containing materials (ACMs) and one hydrocarbon contaminated area. The locations of the exploratory holes are presented on **Figure 14.6**.

14C.2.6 Intrusive investigations identified the presence of variable depths of Made Ground across the BDAE, ranging from absent to a proven depth of 9.0m (GB4) within the mounds. Made Ground deposits have been found to typically comprise either reworked natural soils (weathered Blue Lias Formation deposits comprising mudstone and limestone), or demolition and construction materials. Natural superficial (drift) deposits have only been rarely encountered within the BDAE, having been identified in DBH2_23, GB6 and TE61. Apparent sediment deposits (believed to be associated with former infilled ponds) were also identified within TE13 and Tr2_5.

14C.2.7 Natural Blue Lias deposits (bedrock) were observed at depths ranging from 0.1m bgl (DBH2_24) and 9.0m bgl (GB4). These deposits comprise an interbedded sequence of mudstone and limestone units. The upper mudstone units were frequently noted to have been significantly weathered to a clay-like deposit. Further details of the ground conditions encountered are presented within the Phase 2 Contamination Assessment report (Ref. 14.93) and within section 14.5.

14C.2.8 Selected soil samples collected during the investigations were analysed for a range of determinands including metals and metalloids (arsenic, cadmium, chromium, hexavalent chromium, lead, mercury, copper, nickel, zinc, selenium and water soluble boron), pH, sulphate, total monohydric phenols, total cyanide, sulphide, elemental sulphur, total TPH C8-C35, speciated PAHs, speciated TPH, VOCs, Semi-Volatile Organic Compounds (SVOCs), Polychlorinated Biphenyls (PCBs) and asbestos. In addition, selected samples were also submitted for Waste Acceptance Criteria (WAC) and soil leachate analysis. Detailed forensic hydrocarbon analysis has also been undertaken on a number of samples from hydrocarbon contaminated soils.

14C.2.9 Given the probable time since the sewage works were decommissioned, (at least 10-20 years ago), the chances of any micro-organisms being present is considered to be very low and therefore testing for such contaminants was not considered necessary.

14C.2.10 Supporting information concerning details of the investigations including analytical certificates, details of methodologies and soil descriptions are provided within the Phase 2 Contamination Assessment report (Ref. 14.93).

14C.2.11 A summary of the results is presented in **Table 14C.5** to **Table 14C.8**. These results were used to conduct a Tier 1 risk assessment using human health, phytotoxic and built environment SSVs (see **Table 14C.5** and **Table 14C.7** for Made Ground and natural ground respectively). **Table 14C.6** and **Table 14C.8** provide a summary of the ecological risk assessment for the Made Ground and natural soil, respectively. A staged approach to ecological risk assessment has been adopted, whereby contaminant concentrations have initially been compared with Stage 1 ecological SSVs (Ref. 14.64) and then, where necessary, with the Stage 2 Rural England maximum background soil concentrations (Ref. 14.69 and Ref. 14.70) and subsequently with Stage 3 local background concentrations i.e. the range of concentrations recorded within soils on the BDAW (Ref. 14.84 and Ref. 14.86).

14C.2.12 Where appropriate the analytical results were subject to statistical tests, using the statistical approach recommended by CL:AIRE/CIEH 'Guidance on Comparing Soil Contamination Data with a Critical Concentration' (Ref. 14.101), resulting in the UCL of the true population mean for each contaminant being compared to the Critical Concentrations (Tier 1 SSVs). For the purpose of this statistical analysis the data was treated as belonging to two main 'populations' (in statistical terms), Made Ground and natural soils, and grouped by geographical area (i.e. the six assessment areas based on current and historical land use and topography, shown in **Figure 14.4** and **Figure 14.6**). The exception to this is Area 3 (double-humped mound) which contained a significant thickness of Made Ground and therefore was separated into three separate Made Ground populations for statistical analysis. The summary in **Table 14C.5** provides the range of all UCL values observed in Made Ground in the BDAE, i.e. Made Ground for Areas 1,2,4,5 and 6 and all three Made Ground populations for Area 3. The range of UCL values observed in the natural soils in the BDAE is presented in **Table 14C.7**.

Table 14C.5: Summary of Chemical Analysis Results for Made Ground Soils on the Built Development Area East and Tier 1 Risk Assessment

All units mg/kg unless otherwise stated

< - Value below laboratory limit of detection

* Wessex Water revised threshold for arsenic. Wessex Water Soil Survey Guidance

FC - Based on the value for free cyanide as no total cyanide screening value exists

TP - Based on the Total Phenol concentration

P - Based on the Phenol concentration

P - Assessment of the combined concentrations of both m and p isomers, based on the lower Tier 1 concentration for p-xylene

^ - In line with the Environment Agency approach in the published SGVs, the GAC presented has been capped at the soil saturation limit

~ - Statistical outliers have been retained in the dataset as these values are not considered to represent a separate population

ND - None detected

NC - Not Calculated

a) Forensic Hydrocarbon Analysis

14C.2.13 A selection of soil, weathered rock and free-phase product samples taken from exploratory holes in the vicinity of TE418 and CBH2_54 in Area 4 of the BDAE (in which evidence of hydrocarbon contaminated soils was noted during exploratory works and during groundwater monitoring in CBH2_54) were submitted to Jones Environmental Ltd for tiered forensic hydrocarbon analysis (Tiers 1 to 3). **Table 14C.9** presents a summary of the soil samples submitted for forensic testing. For full details please refer to the Phase 2 contamination report (Ref. 14.93).

14C.2.14 Due to the specific targeted sampling undertaken, including sampling from depths at which no direct excavation of materials is anticipated during construction works (i.e. CBH2_55 ES1 23.1 to 23.5m bgl), the use of these samples to further characterise soils within Area 4 for human health risk purposes is not considered to be appropriate. Therefore, the results of forensic analysis are presented below but are not included or discussed within the Tier 1 soil risk assessment.

Table 14C.9: Summary of Samples Scheduled for Forensic Testing

Exploratory Hole	Depth	Reference	Field Description of Contamination
TE418D	0.6 – 0.75	ES1	Visible free product, comprising viscous black substance and hydrocarbon odour.
CBH2_55	23.1 – 23.5	ES1	Faint hydrocarbon odour in clay parting.
CH2_56	4.4 – 4.5	ES4	Hydrocarbon sheen in fissures in mudstone. During drilling the water on the gravels had a rainbow sheen with a strong kerosene odour.
CBH2_57	6.0 – 6.1	ES1	Slight sheen on flushing and slight hydrocarbon odour within clay when broken.

14C.2.15 The results of the Tier 1 forensic analysis recorded concentrations of total Extractable Petroleum Hydrocarbons (EPH) ranging from 191mg/kg (CBH2_55 ES1) to 735mg/kg (CBH2_57 ES1). The sample of free product (TE418D ES1) was reported, as anticipated, to have a very high EPH concentration (11,758mg/kg).

14C.2.16 The Tier 2 forensic analysis indicated that the likely source of contamination for each of the four samples was anthropogenic and likely to be sourced from heavy fuel oils or middle distillates, and that the hydrocarbon species present in the sampled soil was most likely to be from a crude oil or heavy fuel oil source rather than lube oil.

14C.2.17 Tier 3 forensic analysis confirmed correlations between samples CBH2_55 ES1 and CBH2_57 ES1 (derived from a similar middle distillate) and between samples CBH2_56 ES4 and TE418D ES1 (derived from a biodegraded heavy fuel oil of greater age than that in CBH2_55 and CBH2_57). The correlation between CBH2_56 and TE418D is expected, given that they were both advanced in order to delineate the extent, (both vertical and lateral), of shallow hydrocarbon contaminated soils identified within the Made Ground at sampling location TE418. Although samples from CBH2_55 and CBH2_57 are correlatable, the distance between the two (nearly 160m) means that it is unlikely that the same source zone is responsible for the hydrocarbons in these two locations, particularly given the variation in depth at which the sampled contamination was evident and the absence of identified hydrocarbon impact in nearby borehole DBH2_26 (located to the west of CBH2_57, close to the northern site boundary).

14C.2.18 During routine groundwater level monitoring of CBH2_54 (an uninstalled open hole at the time) free product was identified in the form of Light Non-Aqueous Phase Liquid (LNAPL) adhering to the groundwater level probe. A sample of free product was subsequently taken in May 2010 and the results of the TPH CWG analysis were interpreted by The Environmental Laboratory (ELAB) to be a weathered (degraded) diesel with some trace amounts of a heavier oil (>C28), which was considered likely to be lube oil. ELAB aged the product at approximately 3.5 years. In September 2010 the results of the ELAB analysis (including chromatogram traces from ELAB) were provided to Jones Environmental Ltd. for forensic interpretation and comparison with the four samples which are described above. The interpretation (Ref. 14.93) found that the sampled product was most likely to be a middle distillate of indeterminate age, with no sign of biodegradation but evidence of significant weathering or water washing. The data review also indicated that the oil was unlikely to be derived from a natural oil shale source.

14C.2.19 The results of forensic analysis on soil samples from CBH2_55, CBH2_56, CBH2_57 and TE418, and the interpretation of the gas chromatogram from the sample of free product from CBH2_54, indicate that the hydrocarbon contaminated soils and/or groundwater identified within all of these locations is of anthropogenic origin, and none of the observed hydrocarbons are of natural origin such as those often associated with locally occurring oil shales.

14C.2.20 The results of analysis together with field observations of the extent of visual and olfactory evidence of hydrocarbon contaminated soils in the vicinity of trial pit TE418 (TE418A-E and CBH2_56) shows that the contamination identified within shallow natural soil in CBH2_56 has migrated to that depth from a source zone in the region of TE418, which is likely to comprise leakage from a former above ground storage tank which was present in that location, as identified from aerial imagery as reported in the Desk Based Assessment (Ref. 14.91).

14C.2.21 Monitoring and sampling and analysis of groundwaters has been undertaken at the hydrocarbon affected boreholes CBH2_54, CBH2_55, CBH2_56 and CBH2_57. Details of this monitoring are provided in **Chapter 15** of this volume (Groundwater).

14C.2.22 In addition to the analysis of the samples identified above for forensic hydrocarbon testing, three samples of shallow natural soil (CBH2_56 ES3 3.0-3.15m bgl, CBH2_56 ES4 4.4-4.5m bgl and CBH2_57 ES1 6.0-6.1m bgl) were scheduled for analysis by Jones Environmental Ltd for speciated PAHs, TPH CWG and BTEX testing (Ref. 14.93). **Table 14C.10** presents a summary of the results of analysis on these samples.

b) Waste Acceptance Criteria

14C.2.23 As part of the investigation Waste Acceptance Criteria (WAC) analysis has been scheduled on 23 samples from across the BDAE to provide an initial assessment of the waste acceptance classification which materials may fall into should they require disposal off-site. All samples analysed were of Made Ground material with the exception of two samples of natural soil materials (weathered Blue Lias mudstone in TE12 ES2 and apparent pond sediment in TE13 ES4).

14C.2.24 Certificated full WAC test data and tables are provided within the Phase 2 Contamination Assessment report (Ref. 14.93). **Table 14C.11** below provides a summary of the WAC results across the BDAE (presenting 10:1 leachate results only, and excluding the 2:1 and 8:1 leachability test results which contribute to the 10:1 value) and highlights any exceedences of the WAC screening values.

Table 14C.11: Summary of Waste Acceptance Criteria Analysis and Comparison with Waste Acceptance Criteria

Determinand	Range of Concentrations (mg/kg Unless Stated)	Inert Waste Landfill (Number of Exceedences in Bold)	Stable Non-reactive Hazardous Waste in Non-hazardous Landfill (Number of Exceedences in Bold)	Hazardous Waste Landfill (Number of Exceedences in Bold)

If no value is presented in brackets then no samples exceeded the screening criteria for that contaminant.

c) Soil Leachability Analysis

14C.2.25 Soil leachability testing has been carried out on fifteen samples comprising two samples of natural soils, eight samples of Made Ground containing construction and demolition materials (including two samples from hydrocarbon impacted trial pit TE418 which were analysed for PAHs and TPHs only) and five samples of Made Ground comprising reworked natural soils. The soil leachability results have been used to conduct a Tier 1 controlled waters risk assessment in accordance with the methodology presented in the Phase 2 Contamination Assessment report (Ref. 14.93).

14C.2.26 A summary of the results is presented in **Table 14C.12** and further details are presented in the Phase 2 Contamination Assessment report (Ref. 14.93).

Table 14C.12: Summary of Leachate Analysis Results for the Built Development Area East and Tier 1 Risk Assessment

If no value is presented in brackets, no samples exceeded the screening criteria

#	Corrected based on the reported average hardness value (399mg/l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009
-	No current threshold value available
DPA	River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2010 Part 7 Groundwater Threshold Values for Groundwater Drinking Water Protected Areas
D	Dissolved
T	Total
A	Annual Average
P	95-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 5% of the time or more)
P90	90-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 10% of the time or more)
P5	5-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is less than the standard for 5% of the time or more)
MAC	Maximum Allowable Concentration

C5	Cadmium EQS based on class 5 hardness (>200mg/l $CaCO_3$), corrected based on the reported average hardness value (399mg/l $CaCO_3$) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l $CaCO_3$) recorded during monitoring in 2009
GC	Threshold value based on 'good standard' for transitional and coastal waters to meet objective of WFD for Bridgewater Bay to achieve good ecological status by 2027 (no chemical criteria target thresholds specified)
G15	Threshold value based on 'good standard' to meet objective of WFD for Stogursey Brook to achieve good status by 2015
FCN	Threshold value for free cyanide (as HCN)
I	Imperative Value
T7	Type 7 surface water
As	Threshold value assumed to be total concentration as not defined in the directive and based on percentage of current DWS values
H	Threshold value for high standard based on current WFD Status
* LOD	Exceedences of the annual average EQS have occurred due to the limit of detection (LOD) not being low enough. This is a consequence of the current methodologies of analysis for these parameters. However, these ‘exceedences’ are not considered to be environmentally significant
^	Guideline Value – Non statutory/proposed EQS, but EQS never adopted in UK
^^	The parametric value applies to the sum of the concentrations of benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(ghi)perylene and indeno(1,2,3-cd)pyrene detected and quantified in the monitoring process
^^^	The individual concentrations are based on the 0.1µg/l quoted for the sum of the four PAH compounds. By virtue of the total Tier 1 concentration being reported as 0.1µg/l the Tier 1 concentration for each individual compound has been applied at this value

d) Southern Construction Phase Area

14C.2.27 Intrusive investigations within the Southern Construction Phase Area (SCPA) were undertaken in June 2010 (Ref. 14.93). The works comprised nine window sampling holes advanced up to 5m bgl and six hand dug pits, advanced up to 1.2m bgl. Eight boreholes were also advanced to a maximum depth of 15m bgl (with the exception of CBH2_49 which was advanced to 60.8m bgl) for gas and/or groundwater monitoring or geotechnical purposes. Made Ground was encountered at one location only (WS75) extending to 0.79m bgl and at the other locations ground conditions generally comprised of topsoil over natural superficial deposits or weathered mudstone. The exploratory holes were positioned to provide coverage of the SCPA in general and to target possible infilled former ponds. Sampling locations are presented within the Phase 2 Contamination Assessment Report (Ref. 14.93).

14C.2.28 Selected soil samples collected during the investigation were analysed for a range of determinands including metals and metalloids (arsenic, cadmium, chromium, hexavalent chromium, lead, mercury, copper, nickel, zinc, selenium, water soluble boron), pH, sulphate, total monohydric phenols, total cyanide, sulphide, elemental sulphur, total TPH C8-C35, speciated PAHs, speciated TPH and asbestos.

14C.2.29 Supporting information concerning details of the investigations including analytical certificates, details of methodologies and soil descriptions are provided within the Phase 2 Contamination Assessment report (Ref. 14.93).

14C.2.30 The results have been divided into samples of Made Ground (one sample only) and natural soils (seventeen samples) and a summary of the results is presented in **Table 14C.13**. These results were used to conduct a Tier 1 risk assessment using human health, phytotoxic and built environment SSVs and **Table 14C.14** provides a summary of the ecological risk assessment. As a conservative approach contaminant concentrations have been compared to human health SSVs for residential without plant uptake land use, in consideration of the proposed use of part of the SCPA as an accommodation campus for workers at the HPC site. A staged approach to ecological risk assessment has been adopted, whereby contaminant concentrations have initially been compared with Stage 1 ecological SSVs (Ref. 14.64) and then, where necessary, with the Stage 2 rural England background soil concentrations (Ref. 14.69 and Ref. 14.70) and subsequently with Stage 3 local background concentrations, i.e. the range of concentrations recorded within soils on the BDAW (Ref. 14.84 and Ref. 14.86).

14C.2.31 The analytical results for natural soils were subject to further statistical tests, using the statistical approach recommended by CL:AIRE/CIEH ‘Guidance on Comparing Soil Contamination Data with a Critical Concentration) (Ref. 14.71). The resultant UCL for each contaminant was compared to the Critical Concentrations (Tier 1 SSVs) and these are also presented in **Table 14C.13**.

Table 14C.13: Summary of Chemical Analysis Results for Locations on the Southern Construction Phase Area and Tier 1 Risk Assessment

Determinand	Concentration in Made Ground (One Sample)	Range of Concentration in Natural Soils	UCL Natural Soils	Tier 1 Human Health SSV	Tier 1 Phytotoxic SSV	Tier 1 Built Environment SSV (WRAS Threshold Value Unless Stated)	Exceedence of Tier 1 Human Health SSV (Number of Samples)		Exceedence of Tier 1 Phytotoxic SSV (Number of Samples)		Exceedence of Tier 1 Built Environment SSV

b1. Reported range for selenium in normal soils in the UK (Adriano 2001). UK Soil and Herbage Pollutant Survey (UKSHS) Report No. 7, Environmental Concentrations of Heavy Metals in UK Soils. Environment Agency.

c. Range of Concentrations Recorded in rural soils in England . UK Soil and Herbage Pollutant Survey (UKSHS) Report No. 9, Environmental Concentrations of PAHs in UK Soil and Herbage. Environment Agency.

14C.2.32 The concentrations recorded in the soil samples from both Made Ground and natural soils were below the human health Tier 1 assessment criteria for residential without plant uptake land use. Levels of pH were in slight exceedence of the BS3882:2007 Topsoil Specification (Ref. 14.57) limit value (8.5 pH units) in four natural soil samples (up to 8.9 pH units), however, these slightly alkaline pH levels are not considered to pose a risk to human health. No asbestos containing materials were found in any of the exploratory holes on the SCPA.

14C.2.33 Contaminant concentrations in soil samples from both the Made Ground and natural soils were below the phytotoxic SSVs, with the exception of one sample of natural soil (WS713 ES4) which exceeded the water soluble boron phytotoxicity SSV (31.6mg/kg compared to 3mg/kg). This sample was taken from a horizon of peat extending to depths ranging from 1.71m bgl to 3.59m bgl and as such the elevated boron concentration is considered to be of natural origin. This isolated exceedence is not considered to pose a significant phytotoxic risk.

14C.2.34 In general, the concentrations of the determinands which may pose a risk to concrete structures and water supply pipe materials have been recorded below the Tier 1 criteria with the exception of sulphate and pH levels. The one Made Ground sample (WS75 ES1) and six of the seventeen natural soil samples exceed the WRAS (Ref. 14.60) sulphate limit (0.2%) and all but one natural soil sample also exceed the BRE SD1 (Ref. 14.62) sulphate value (0.24%). The elevated sulphate concentrations noted in the natural soils are considered to be of natural origin, as no evidence of anthropogenic contamination of the natural soils was noted, and the SCPA has no history of potentially contaminative use with respect to sulphate. Eleven of the natural soil samples and the Made Ground sample also exceeded the WRAS Tier 1 upper threshold for pH. The presence of naturally elevated pH and sulphate levels may pose a low risk to potable water supply pipes and buried concrete structures.

14C.2.35 One sample of natural soil (WS714 ES4), taken from natural alluvial strata, was found to exceed the WRAS threshold for cadmium. The cadmium concentration (5.2mg/kg) in this sample is noticeably higher than in other natural soil samples on the SCPA. However, this concentration is considered to be naturally occurring, as an elevated cadmium concentration was also identified in natural soil on the BDAW.

14C.2.36 Elevated concentrations of chromium, mercury, zinc and selenium have been recorded in the Made Ground sample when compared to the conservative ecological SSVs, however concentrations are within the English background concentration ranges. Concentrations of arsenic, chromium, cadmium, mercury, copper, nickel, zinc and selenium in natural soils were also found to exceed the ecological SSVs. Comparison with the rural England and local background concentration ranges indicates marginally elevated cadmium and nickel in one sample (TE714 ES4). However, these concentrations are considered to be naturally occurring and given concentrations of contaminants on the SCPA are generally consistent with background concentrations, the risk posed to ecological systems from contaminants within the soils on the SCPA is considered to be negligible.

14C.2.37 Overall the intrusive investigations of soils within the SCPA have identified the risk of significant non-radiological contamination being present to be very low.

APPENDIX 14D: SUMMARY OF RADIOLOGICAL INVESTIGATIONS FOR THE HPC DEVELOPMENT SITE

14D.1 Baseline Non-Intrusive Radiological Surveys

14D.1.1 Baseline non-intrusive radiological surveys have been undertaken across the different areas of land within the HPC Development Site. Measurements were taken using a Mini 6-80/MC7 a low-background Geiger-Muller detector designed for environmental gamma dose rate measurement using the methods outlined in the Environment Agency Guidance TGNM5 – Monitoring (Ref. 14.50). Integration period of 600 seconds was used for each measurement. Measurements were used to determine the excess radiation dose that would be received by a person who was occupying the site from the presence of any gamma emitting radionuclides in the ground. The measurements permitted the evaluation of the external radiation hazard to humans on the HPC Development Site in its current state.

14D.1.2 To complement the gamma dose rate measurements a walkover survey using a Thermo G2 probe and an Electra ratemeter, which is a sodium iodide scintillation detector designed for the detection of gamma radiation. This was set up to detect gamma photons of energy 60keV to approximately 1.5MeV (this is the full range of operating parameters for the equipment). This instrument is capable of detecting low levels of activity in the shallow ground to a maximum depth of ~0.4m below ground level (bgl). Below this depth and dependent on the ground surface type, gamma activity will be detected if sources emitting greater levels of activity or at higher energy are present. Radiological survey locations were randomly selected to afford good coverage of the different areas of land within the HPC site, a number of targeted survey points were also selected to cover areas of interest on the BDAE.

14D.1.3 The field readings were compared to background concentrations taken at a cemetery site near Bridgwater using both the G2/Electra and the Mini 6-80/MC71. Measurements were taken over undisturbed ground within the cemetery where no grave digging had occurred. The readings were taken at spot locations, with counts for both being recorded for either 60 or 600 seconds respectively.

14D.2 Built Development Area West

14D.2.1 A baseline intrusive survey was carried out in 2008 which involved a non-intrusive radiological survey, including a radiological walkover survey and environmental gamma dose rate measurements (see above), together with an intrusive investigation involving the collection, and radiochemical analysis, of 20 near surface soil samples (surface scrapes <0.2m bgl). The samples were analysed for the following determinands: gross alpha (calibrated with americium-241); gross beta (calibrated with potassium-40); high-resolution gamma spectrometry and water-extractable tritium. Analytical reports, details of methodology etc. are included within the Baseline Radiological Survey report (Ref. 14.85).

14D.2.2 The information obtained during the baseline intrusive survey was augmented by a Phase 2 Supplementary Investigation of Potential Radiological Contamination (Ref. 14.87). Soil samples were collected from the trial trenches excavated in 2008. (See **Figure 14.9)**.

14D.2.3 A total of 30 soil samples taken from depths of greater than 0.2m bgl were selected for radiochemical analysis for the following determinands: gross alpha (calibrated with americium-241); gross beta (calibrated with potassium-40); high-resolution gamma spectrometry, total tritium and carbon-14. The samples analysed were selected to assess the contamination status of the deeper soils within the BDAW. Analytical reports, details of methodology etc. are included within the Phase 2 Supplementary Investigation of Potential Radiological Contamination for the Built Development Area West (Ref. 14.87).

14D.2.4 A summary of the results, including data from both the initial survey surface samples and the deeper Phase 2 investigations, is presented in **Table 14D.1**. The Table includes ranges of results, adopted screening and background values and an indication of where results have exceeded any of the adopted screening values, in line with the data assessment approach described above. For details on the approach to data assessment and adopted background and screening values see the Phase 2 report (Ref. 14.87).

[a] Where positive values, i.e. detected values, have been reported, these have been used in preference to "less than" (<) values for presenting the ranges of activity concentration

[b] The sources of the adopted background values are referenced in **Table 14D.2**

[c] The average background value is provided in parentheses

[d] The adopted screening values are derived from the values for the specified elements listed in the Environmental Permitting (England and Wales) Regulations 2010. The screening values are calculated by dividing the elemental limit by the number of isotopes of the radionuclides in the natural radioactive decay series (uranium-238, thorium-232 and uranium-235)

[e] N/A indicates not applicable

[f] Only positive values are used for assessment of numbers of results that exceed screening values. "Less than" values that exceed the screening values are not included

[g] Although the adopted screening value was exceeded, the specified elemental limits described in the Environmental Permitting (England and Wales) Regulations 2010 were not

*Data from RIFE reports 13 (Ref. 14.80) and 14 (Ref. 14.81).

Data from DoE/HMIP/RR/93/063 (1993) (Ref. 14.82).

+ Data from UNSCEAR (2000) (Ref. 14.83).

a) Built Development Area East and Southern Construction Phase Area

14D.2.5 A series of assessments relating to the radiological conditions on the BDAE and SCPA were undertaken.

14D.2.6 A non-intrusive radiological survey (Ref. 14.85), including a radiological walkover survey and environmental gamma dose rate measurements (see Section 14D.1 above), was undertaken on the BDAE and SCPA in October 2009 prior to the commencement of intrusive works. The survey locations are presented in **Figure 14.10** and **Figure 14.12.**

14D.2.7 In general, the walkover survey recorded measurements that were low, being at or below expected background values for the area. The environmental gamma dose rates measured were also generally consistent with background levels. The radiological survey did, however, identify an area of elevated radiation readings close to the eastern boundary of the BDAE land adjacent to HPA. These findings were consistent with a previous walkover survey carried out on the BDAE land by Serco Assurance in 2008 (Ref. 14.49). The annual dose in excess of background based on commercial occupancy of the most elevated survey location would be 0.071mSv a^{-1} based on external radiation only. This constitutes 7.1% of the annual dose limit for members of the public (1mSv a^{-1}) (Ref. 14.105), and is 23.8% of the dose constraint adopted by the Environment Agency (0.3mSv a^{-1}) in their contaminated land guidance (Ref. 14.106).

14D.2.8 Following the non-intrusive radiological survey, the Phase 2 intrusive works on the BDAE and SCPA commenced. From the intrusive investigations a total of 128 soil samples from the BDAE and six soil samples from the SCPA, were collected and submitted for radiochemical analysis for the following determinands: gross alpha (calibrated with americium-241); gross beta (calibrated with potassium-40); high-resolution gamma spectrometry; total tritium; and carbon-14. **Figure 14.11** and **Figure 14.12** provide the sampling locations.

14D.2.9 Supplementary information such as analytical reports and details of methodology are included within the Phase 2 Contamination Assessment (Radiological) of the BDAE and SCPA report (Ref. 14.94). A summary of the results for the BDAE are provided in **Table 14D.3** and for the SCPA in **Table 14D.4**. The tables provide a comparison of the results with the screening and adopted background values, where available. In addition, the gross alpha and gross beta results were compared with those obtained for the BDAW for consistency between the two datasets.

[a] Where positive values, i.e. detected values, have been reported, these have been used in preference to "less than" (<) values for presenting the ranges of activity concentration

[b] The sources of the adopted background values are referenced in **Table 14D.2**

[c] The average background value is provided in parentheses

[d] The adopted screening values are derived from the values for the specified elements listed in the Environmental Permitting (England and Wales) Regulations 2010. The screening values are calculated by dividing the elemental limit by the number of isotopes of the radionuclides in the natural radioactive decay series (uranium-238, thorium-232 and uranium-235)

[e] N/A indicates not applicable

[f] Only positive values are used for assessment of numbers of results that exceed screening values. "Less than" values that exceed the screening values are not included

14D.2.10 During the Phase 2 intrusive survey works, two locations were identified along the western boundary of the BDAE (TE312 and GB2, see **Figure 14.11**) that provided elevated radiation readings during routine health physics monitoring which was undertaken throughout the on-site works (i.e. the Phase 2 intrusive investigations). As a result of this, a further six samples were collected from the two locations and submitted for radiochemical testing for a range of determinands that would enable the identification and quantification of a wide range of both naturally occurring and anthropogenic radionuclides: gross alpha (calibrated with americium-241); gross beta (calibrated with potassium-40); high-resolution gamma spectrometry; total tritium; carbon-14; plutonium isotopes; strontium-90; nickel-63 and iron-55. A comparison of the results for these samples with those reported for the other samples collected from the BDAE is presented in **Table 14D.5**. All analytical data are included within the Phase 2 Contamination Assessment (Radiological) of the BDAE and SCPA report (Ref. 14.94).

[a] Range is based on the results for 120 samples collected and analysed as presented in **Table 14D.3**
[b] N/A indicates not applicable
[c] D indicates a duplicate sample
[d] NM indicates not measured

14D.2.11 The results for the samples collected from GB2, TE312, TE312A and TE312B provide no evidence of contamination by anthropogenic radionuclides. However, the levels of naturally occurring radionuclides from the uranium-238 and uranium-235 decay series from selected locations (GB2, TE312 and TE312A) were elevated when compared with the range of results observed for the rest of the BDAE. The levels of uranium-238 series radionuclides observed at these locations fell within the range of 1 - 2Bq g^{-1}. This compares with an upper level for these radionuclides in samples collected from the rest of the site of approximately 0.09Bq g^{-1}. The gross alpha and gross beta levels were also elevated compared with the rest of the site due to the elevated levels of these naturally occurring radionuclides.

14D.2.12 The levels of uranium-238 and uranium-235 natural series radionuclides in the samples from these locations are such that the levels of lead, polonium, protactinium, radium and thorium exceed their respective EPR 2010 (Ref. 14.19) elemental limits. However, the levels of all of these elements are below the Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (Ref. 14.79) limit of 14.8Bq g-1 and hence should be exempt from radioactive substances regulation.

14D.2.13 In summary, the radiochemical analysis results for the soil samples from the BDAE and SCPA show that there is no evidence of significant contamination with anthropogenic radionuclides and that the levels of radionuclides present are generally consistent with background levels:

- The only anthropogenic radionuclides detected were caesium-137 and americium-241. The levels of caesium-137 detected were consistent with background due to global atmospheric fallout. Americium-241 was detected in two samples at low levels. Overall, levels of anthropogenic radionuclides detected were significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- The levels of anthropogenic radionuclides detected were significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- Carbon-14, which can be present both naturally and from anthropogenic sources, was detected in a number of the samples at levels consistent with adopted background values. The levels detected were significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g-1.
- Tritium which can be present both naturally and from anthropogenic sources, was detected in one sample at a level close to the limit of detection and significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- With the exception of samples collected from locations in Area 6 (TE312, TE312A and GB2), gross alpha and gross beta results were consistent with values reported for the BDAW.
- With the exception of samples collected from three locations in Area 6 (TE312, TE312A and GB2), the levels of naturally occurring radionuclides present would not result in the levels of specified radioelements exceeding EPR2010 (Ref. 14.19) limits.

The only locations where elevated levels of radionuclides were observed along the western boundary of the BDAE (TE312, TE312A and GB2). The samples from these locations contained elevated levels of natural uranium and associated daughter products. Although the levels of some of the EPR2010-specified elements present in these samples exceed their associated limits, they are below the Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (Ref. 14.79) limit of 14.8Bq g-1 and hence would be exempt from radioactive substances regulation. The elevated natural uranium is likely to be associated with granite chippings observed at these locations.

APPENDIX 14E: SUMMARY OF GAS MONITORING RESULTS FOR THE HPC DEVELOPMENT SITE

APPENDIX 14E: SUMMARY OF GAS MONITORING RESULTS FOR THE HPC DEVELOPMENT SITE

14E.1 Built Development Area West

14E.1.1 A programme of ground gas monitoring has been undertaken within the Built Development Area West. Six gas monitoring visits were undertaken between January 2009 and April 2009 at ten piezometer locations (installed as part of the on-shore investigation undertaken by Structural Soils Ltd in 2008). The monitoring locations are presented in **Figure 14.13**. Gas monitoring was undertaken in accordance with requirements set out in guidance document Construction Industry Research and Information Association (CIRIA) 665 ‘Assessing risks posed by hazardous ground gases to buildings’ (2007) (Ref. 14.76).

14E.1.2 During one visit, six gas samples were taken from selected locations and submitted for laboratory analysis to determine concentrations of methane, carbon dioxide, oxygen, carbon monoxide, hydrogen sulphide, nitrogen, hydrocarbons (n-alkanes) C1 to C8 and volatile organic compounds. The laboratory analysis was carried out to confirm field data and provide confidence that the field monitoring technique was robust. A summary of the gas monitoring results is presented in **Table 14E.1**.

14E.1.3 Details of the methodology, assessment, full monitoring data and analytical certificates are presented in the Final Ground Gas Risk Assessment report for Built Development Area West (Ref. 14.88).

Table 14E.1: Summary of Data from Six Gas Monitoring Visits for Boreholes within the Built Development Area West

LOD = Limit of Detection.

Unless stated all values are the stable concentrations.

MMGBA = Mercia Mudstone Group Blue Anchor, BLF = Blue Lias Formation, PG = Penarth Group, MG = Made Ground, SF = Superficial (A) = Alluvium

Where measurements have been taken to the top of a standpipe or casing, the static water level has been calculated to meters below ground level (level minus standpipe/casing height).

< Less than LOD, variable per compound.

14E.2 Built Development Area East and Southern Construction Phase Area

14E.2.1 A programme of ground gas monitoring was undertaken within the BDAE and SCPA in accordance with the requirements presented in guidance document CIRIA C665 (Ref. 14.76). Eight monitoring visits were undertaken between June 2010 and September 2010. The monitoring programme was extended to eight monitoring visits to ensure that all piezometers had been monitored on at least six occasions, in accordance with the CIRIA C665 guidance. Monitoring was undertaken at 11 piezometers in the BDAE, seven piezometers in the SCPA and two piezometers in the BDAW (the two BDAW boreholes were selected for routine monitoring during the BDAE and SCPA monitoring programme as elevated flow rates and calculated borehole nitrogen concentrations were identified during drilling). The monitoring locations are presented on **Figure 14.14**, **Figure 14.15** and **Figure 14.13** respectively. A summary of the gas monitoring results is presented in **Table 14E.2**.

14E.2.2 During the fourth monitoring visit, eight gas samples were taken from selected piezometers and submitted for laboratory analysis to determine concentrations of methane, carbon dioxide, oxygen, carbon monoxide, hydrogen sulphide, nitrogen and volatile organic compounds. The laboratory analysis was carried out to confirm field data and provide confidence that the field monitoring technique was robust.

14E.2.3 Details of the methodology, assessment, full monitoring data and analytical certificates are presented in the Ground Gas Risk Assessment report for the Built Development Area East and Southern Construction Phase Area (Ref. 14.95).

APPENDIX 14G CONCEPTUAL MODEL TABLES

Table 14G.1: Conceptual Site Models

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
Actual and potential contaminants associated with the previous and current land uses on the BDAE, BDAW and SCPA and in the surrounding area The list of off-site contaminants is intended to be indicative, not exhaustive Actual **on-site soil** sources and associated contaminants identified are: **BDAE** Undeveloped land/Infilled Ponds (Area 1/TE13) • Boron > phytotoxic SSV • Sulphate in excess of WRAS and BRE threshold • pH (Made Ground) > WRAS Former Accommodation camp/ Contractors compound (Area 2) • Se and pH in excess of WRAS • Sulphate in excess of WRAS and BRE threshold • Hydrocarbons >WRAS • PAHs > ecotoxicological Stage 1	• Indoor soil vapour and ground gas inhalation from ingress of ground gases and vapours via service entry points and cracks/joints (1) • Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4)	**Humans** • Users of and visitors to the BDAE, BDAW and SCPA • Off-site Human Receptors (walkers, residents, adjacent land users)	**Current Land Use. Baseline (Before Enabling/Remedial Works)** **Linkage unlikely. Low risk.** • On the basis of the site investigation, concentrations of non radiochemical and radiochemical contaminants on the study site are not generally significantly elevated (there have been no exceedences of Tier 1 human health risk assessment criteria, with the exception of some elevated pH readings, however these are most likely to be attributable to mortar and plaster in construction and demolition materials and as they are all <pH 11.5 and >pH 5 are unlikely to pose a risk to human health even though they exceed the conservative Tier 1 criteria). An exception to this is the presence of an isolated zone of hydrocarbon contamination in the vicinity of TE418 and CBH2_56 (exceeds conservative Tier 1 SSV for aliphatic C12-C16 TPH) within Area 4 on the BDAE which poses a potentially significant risk to human receptors, although the ground conditions encountered during site investigations showed this contamination to be present beneath a confining layer of hard standing at 0.6m bgl, therefore the potential for exposure to human receptors at surface is limited. Also slightly elevated concentration of benzo(a)pyrene was noted in TE63 in Area 6 but the overall UCL for Area 6 was below the SSV. A sample from CBH2_57 also exceeded the conservative Tier 1 SSV for aliphatic C12-C16 TPH, however this is a very conservative SSV based on solubility saturation and the actual human health based risk value is much higher. The concentration of aliphatic C12-C16 TPH in CBH2_57 is therefore not considered to be a risk. The presence of asbestos containing materials (ACMs) within Made Ground in Area 2, Area 3, Area 4, Area 5 and Area 6 has been confirmed, however these materials have not been witnessed exposed at surface, and due to the presence of surface vegetation and hard standing across the affected areas the potential for airborne fibre release is currently considered negligible. Also, to date no concentrations of free fibre >0.01% w/w within the soil matrix have been detected even in locations where fragments of ACM have been detected with the exception of one location (TE55/WS55A) in Area 6.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
SSVs, Stage 2 and 3 background values • Se > ecological Stage 1 SSVs and Stage 2 and 3 background values • Asbestos Former Spoil Disposal Areas (Area 3) • Asbestos • Boron > phytotoxic SSV • Se > ecotoxicological Tier 1 SSVs Stage 2 and 3 background values. • pH in excess of WRAS • Se in excess of WRAS • Hydrocarbons >WRAS • PAH >WRAS, ecological Stage 1 SSVs and Stage 2 and 3 background values. • Sulphate in excess of WRAS and BRE threshold Former Fabrication Areas (Area 4 and Area 5) • Asbestos • Cu, Se, Zn exceeding ecological Tier 1 SSVs and Stage 2 and 3 background values.	• Migration of contaminants via agricultural drainage Ditches/Bristol Channel (6) • Air/wind transport (on and off-site) (8) • Indoor soil vapour and ground gas inhalation from ingress of ground gases and vapours via service entry points and cracks/joints (1) • Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/migration via permeable ground (5) • Transfer of contaminants via	• Construction workers • Users and visitors to the site • Off-site Human Receptors (walkers, residents, adjacent land users etc).	• • No exceedances of human health Tier 1 criteria have been noted on BDAW and SCPA. **Construction Phase (Post Enabling/Remedial Works)** **Linkage to soil contaminants possible. Low risk**. • On the basis of the intrusive investigations to date, no concentrations of non radiochemical and/or radiochemical contaminants in excess of Tier 1 human health criteria have been identified to date with the exception of some limited areas of the site, where the presence of asbestos containing materials within Made Ground soils in Area 2, Area 3, Area 4, Area 5 and Area 6 poses a potential risk during ground works to construction/ground workers and to members of the public/power station workers downwind of the working area and a localised zone of significantly elevated hydrocarbon contamination within Area 4. However, all known hotspots of ACM and the hotspot of significant hydrocarbon contamination around TE418 will have been removed during the enabling/remedial works. • Any additional contamination identified during the earthworks/construction will need to be assessed to determine the potential risks posed, and subsequently removed and/or remediated as required. • Soil material proposed for re-use will be further analysed and assessed during earthworks to determine if ‘suitable for use’ from an environmental point of view as part of the Materials Management Plan and Soil Management Plan. • Risk of mobilising contamination/pollution incidents is always

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
• Zn, Cu > phytotoxic SSV • pH in excess of WRAS • Sulphate in excess of WRAS and BRE threshold • Hydrocarbons > ecological Stage 1 SSVs (TE418 area), Human health SSVs (TE418 area), WRAS • PAHs > ecotoxicological Stage 1 SSVs, background values and WRAS Former NDA Spoil Disposal Area (Area 5) • Asbestos • Cu, Zn, > ecological Stage 1 SSVs and Stage 2 and 3 background values • Zn, Cu > phytotoxic SSV • pH in excess of WRAS • Hydrocarbons >WRAS	surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air/wind transport (on and off site) (8)		increased during major earthworks/construction, however good environmental construction practice/Environmental/Pollution Prevention Management Plans will detail procedures to minimise these risks. • Construction/ground workers are more likely to come into contact with existing contamination due to their proximity and close work with soils/groundwater. Risks can be minimised through use of PPE and good hygiene standards. • Ground gas risk identified on the site is negligible (CIRIA C665 Characteristic Situation 1), which does not require the provision of gas protective measures into the design of the development. The deposits within the double-humped mound feature were noted to generate slightly elevated concentrations of hazardous ground gases and as such poses a potential risk. However the double-humped mound feature will be removed as part of the enabling works and any putrescible materials removed; any associated ground gas risk will thereby be mitigated. Isolated occurrences of elevated VOCs have been identified within shallow monitoring installations and occasional elevated concentrations of nitrogen, methane, hydrogen sulphide, carbon monoxide and carbon dioxide (in addition to depleted oxygen) were identified during health and safety monitoring during deep drilling of natural strata. Contractors should have due consideration for, and assess the health and safety risks of, potential ground gas concentrations and potential mitigation measures (e.g. gas and vapour monitoring), in particular, during any confined space working or during works which are carried out in deep excavations.
Former Sewage Works (Area 6) • Slightly elevated levels naturally occurring radioactivity associated with granite ballast • pH in excess of WRAS • Sulphate in excess of WRAS	• Indoor soil vapour and ground gas inhalation from ingress of ground gases and vapours via service entry points and cracks/joints (1) • Migration via man made pathways such as	• End users • Construction workers during any future construction work on during the operational phase • Users and visitors to the	**Operational Phase (Commercial Land Use in BDAW/BDAE only. SCPA will be agricultural/habitat restoration areas)** **Linkage unlikely to exist post development. Very low risk.** • Majority of BDAW and BDAE will be covered by buildings and hardstanding, so only limited potential pathways available to any residual or new contamination that may occur. • Soils which will have been reused on-site will be 'suitable for use'

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
and BRE threshold • Boron in excess of phytotoxicity SSV. • Benzo(a)pyrene and total PAH (TE63 ES2) > human health SSVs • Benzo(a)pyrene, anthracene, benzo(a)anthracene, indeno(123-cd)pyrene, total PAHs > ecological SSVs and Stage 2 and 3 background values (TE63 ES2)Asbestos • Hydrocarbons > WRAS for TE63 **BDAW** • Heavy Metals – As, Cd, Cr, Ni, Se, Zn etc (in natural ground > Stage 1 ecological SSVs but generally below Stage 2 SSVs (i.e. rural England background) • Water soluble boron (Made Ground in TRE01 only) > phytotoxicity criteria • Zn > Tier 1 Phytotoxicity criteria (TRE01 and TRE21 Made Ground) • As > WRAS but < WWSSG • Occasional elevated Cd in natural ground > WRAS.	drains and underground services (includes permeation into and distribution via water service pipes) (2) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air/wind transport (on and off-site) (8)	site Off-site Human Receptors (walkers, residents adjacent land users)	from an environmental point of view. • Any contaminated soils (within acceptability standards) that will have been reused on site will have been carefully managed by the suitable placement of these materials beneath buildings and areas of hardstanding, and if placed in areas of soft landscaping, agricultural restoration or habitat creation these should not be placed within the upper 1 m of the soil profile. • Post-development, there will be many more potential contaminant sources. The risk of future contamination occurring (e.g. through spills and leaks etc) will be minimised through good Environmental Management Practises and Procedures, monitoring and physical infrastructure (e.g. bunded tanks/containment areas, sealed drainage etc).

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
• Elevated SO4 > WRAS and BRE screening criteria (WS85 and WS86) **SCPA** • Heavy Metals - Cd, Ni (in natural ground sample WS714 ES4) > ecological SSVs and Stage 2 and 3 background values • Water soluble boron (alluvial peat in WS713 only) > phytotoxicity criteria • Slightly elevated pH > WRAS criteria • Elevated SO4 > WRAS and BRE screening criteria • Elevated VOCs (DBH2_13 only) by field PID testing (not validated by laboratory testing) • Other potential sources on BDAW and SCPA.	• Indoor soil vapour and ground gas inhalation from ingress of ground gas and vapours via service entry points and crack/joints (1) • Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7)	<u>Built Environment</u> • Hinkley Point Nuclear New Build Site Induction Centre • Car Parks • Old Barns	<u>**Current Land Use. Baseline (Before Enabling/Remedial Works)**</u> **Linkage Unlikely. Low Risk.** • Slightly elevated soil concentrations of pH, sulphate, and petroleum hydrocarbons in excess of WRAS and BRE guidance noted in several locations in Made Ground and some natural soils on BDAE, BDAW and SCPA. A localised zone of significant soil hydrocarbon contamination has been identified in the vicinity of TE418 in Area 4. Soil contamination levels currently across the site generally do not pose a significant risk to existing built environment. • Extent of current built environment on the site is limited.
<u>Arable Crop Management</u> • Nitrates • Pesticides • Herbicides • Heavy metals • Metals and Metalloids	• Indoor soil vapour and ground gas inhalation from ingress of ground gas and vapours via service entry points and crack/joints (1) • Migration via man made pathways such as drains and underground services (includes	<u>Built Environment</u> • New buildings (BDAE, BDAW) • Contractors Accommodation Buildings (SCPA area) • Contractors offices. • New services (pipelines e.g. sewers, water,	<u>**Construction Phase (Post Enabling/Remedial Works)**</u> **Linkage Unlikely. Very low to low risk.** • Hotspot of significant hydrocarbon in vicinity of TE418 in Area 4 will have been removed. • Any additional contamination identified during the earthworks/construction will need to be assessed to determine the potential risks posed, and subsequently removed and/or remediated as required. • Soil material proposed for re-use will be further analysed and

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
<u>Agricultural vehicle maintenance and use</u> • Hydrocarbons • PAHs <u>Sewage Sludge Application</u> • Heavy Metals • Metals and Metalloids <u>Derelict Farm Buildings</u> • Hydrocarbons • PAHs • Pesticides • Herbicides • Asbestos <u>Infilled Ponds</u> • Heavy Metals • Hydrocarbons • PAHs • Ground Gases • Asbestos **Potential Off-Site Sources**	permeation into and distribution via water service pipes) (2) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via surface run off (6) • Transfer of contaminants via groundwater (7) • Indoor soil vapour and ground gas inhalation from ingress of ground gas and vapours via service entry points and crack/joints (1) • Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via	electric etc) <u>Built Environment</u> • New buildings located on BDAE/BDAW • New services (e.g. sewers, water, electric etc.)	assessed during earthworks to determine if 'suitable for use' from an environmental point of view as part of the Materials Management Plan and Soil Management Plan. • Risk of mobilising contamination/pollution incidents is always increased during major earthworks/construction, however good environmental construction practice/Environmental/Pollution Prevention Management Plans will detail procedures to minimise these risks. • New built environment will be suitably designed and constructed with appropriate specification of materials (e.g. sulphate resistant concrete, Pe/Al/Pe water pipes etc.) to design out any potential risks from residual contamination. • Ground gas risk identified on the site is negligible (CIRIA C665 Characteristic Situation 1), which does not require the provision of gas protective measures into the design of the development **<u>Operational Phase (Commercial Land Use in BDAW/BDAE only. SCPA will be agricultural/habitat restoration areas</u>**) **Linkage unlikely to exist post development. Very low risk.** • The built environment on the BDAE and BDAW post-development will be extensive. However, new built environment will be suitably designed and constructed with appropriate specification of materials (e.g. sulphate resistant concrete, Pe/Al/Pe water pipes etc.) to design out any potential risks from residual or new contamination. • Soils which will have been reused on-site will have been determined as 'suitable for use' from an environmental and geotechnical point of view. • Post development, there will be many more potential contaminant sources. However, the risk of future contamination occurring (e.g. through spills and leaks etc) will be minimised through good Environmental Management Practises and Procedures, monitoring and physical infrastructure (e.g. bunded tanks/containment areas, sealed drainage etc).

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
Hinkley Point Power Station Complex • Hydrocarbons • PAHs • Solvents • PCB • Asbestos • Radioactive materials Lime Kilns • Hydrocarbons • PAHs • Heavy Metals Alluvial deposits (salt marshland at Wick Moor and North Moor) • Ground gases Actual and potential contaminants associated with the previous and current land uses on the BDAE, BDAW and SCPA and in the surrounding area. The list of off-site contaminants is intended to be indicative, not exhaustive.	surface run-off (6) • Transfer of contaminants via groundwater (7) • Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air/wind transport (on-site and off site) (8)	Controlled Waters • Groundwaters on-site and off-site (e.g. Secondary A Aquifer) • Agricultural drainage ditches/streams on-site and off-site • Bristol Channel off-site (N.B. The site and the surrounding area are within a Nitrate Vulnerable Zone).	**Current Land Use/Baseline (Before Enabling/Remedial Works)** **Potential soil linkage identified. Low to moderate risk.** • The results of leachability testing of soils from the site in general are not indicative of the presence of significant contamination within soils with the potential to impact Controlled Waters via leaching. However, a zone of significant hydrocarbon contamination has been identified in the vicinity of TE418 within Area 4 of the BDAE, which was found to contain significant concentrations of TPH (including observations of free phase oil) which may pose a significant leachable risk to Controlled Waters. • Controlled waters on-site are generally low sensitivity. Groundwater is Secondary A Aquifer, no abstractions within 1km of BDAE and BDAW and not within a SPZ. Off-site controlled waters are of (streams and Bristol Channel) low to moderate sensitivity.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
Actual **on-site soil** sources and associated contaminants identified are: **BDAE** Undeveloped land/Infilled Ponds (Area 1/TE13) • Boron > phytotoxic SSV • Sulphate in excess of WRAS and BRE threshold • pH (Made Ground) > WRAS Former Accommodation camp/ Contractors compound (Area 2) • Se and pH in excess of WRAS • Sulphate in excess of WRAS and BRE threshold • Hydrocarbons >WRAS • PAHs > ecological Stage 1 SSVs, Stage 2 and 3 background values • Se > ecological Stage 1 SSVs and Stage 2 and 3 background values • Asbestos	• Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air/wind transport (on and off-site) (8)	Controlled Waters • Groundwaters on and off-site (e.g. Secondary A Aquifer) • Agricultural drainage ditches/streams on and off-site • Bristol Channel off-site (N.B. The site and the surrounding area are within a Nitrate Vulnerable Zone).	**Construction Phase (Post Enabling/Remedial Works)** **Linkage unlikely. Low risk.** • Zone of significant hydrocarbon contamination in vicinity of TE418 in Area 4 of the BDAE will have been removed. • Controlled waters on-site are of low sensitivity. Groundwater is Secondary A Aquifer, no abstractions within 1km of BDAE/BDAW and not within a SPZ. Off-site controlled waters (streams and Bristol Channel) are of low to moderate sensitivity. • Any additional contamination identified during the earthworks /construction will be assessed to determine the potential risks posed, and subsequently removed and/or remediated as required. • Soil material proposed for re-use will be further analysed and assessed during earthworks to determine if 'suitable for use' from an environmental point of view as part of the Materials Management Plan and Soil Management Plan. • Any contaminated soils (within acceptability standards) that will have been reused on-site will have been carefully managed by the suitable placement of these materials beneath buildings and areas of hardstanding, and if placed in areas of soft landscaping, agricultural restoration or habitat creation these should not be placed within the upper 1.0m of the soil profile. • Risk of mobilising contamination/pollution incidents is always increased during major earthworks/construction, however good environmental construction practice/Environmental/Pollution Prevention Management Plans will detail procedures to minimise these risks.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
<u>Former Spoil Disposal Areas (Area 3)</u> • Asbestos • Boron > phytotoxic SSV • Se > ecological Stage 1 SSVs and Stage 2 and 3 background values • pH in excess of WRAS • Se in excess of WRAS • Hydrocarbons >WRAS • PAH >WRAS, ecological Stage 1 SSVs and Stage 2 and 3 background values • Sulphate in excess of WRAS and BRE threshold <u>Former Fabrication Areas (Area 4 and Area 5)</u> • Asbestos • Cu, Se, Zn exceeding ecological Stage 1 SSVs and Stage 2 and 3 background values • Zn, Cu > phytotoxic SSV • pH in excess of WRAS • Sulphate in excess of WRAS and BRE threshold • Hydrocarbons > ecological Stage 1 SSVs (TE418 area), Human health SSVs (TE418	• Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Migration of contaminants via Agricultural Drainage Ditches/Bristol Channel (6) • Air/wind transport (on-site and off-site) (8)	<u>Controlled Waters</u> • Groundwaters on-site and off-site (e.g. Secondary A Aquifer) • Agricultural drainage ditches/streams on-site and off-site • Bristol Channel off-site (N.B. The site and the surrounding area are within a Nitrate Vulnerable Zone).	**<u>Operational Phase (Commercial Land Use in BDAW/BDAE only. Groundwater is Secondary A Aquifer, no abstractions within 1km of BDAE/BDAW and not within a SPZ. Off-site controlled waters (streams and Bristol Channel) low to moderate sensitivity. • Post-development, majority of the main development area will be covered by buildings and hardstanding which will limit infiltration on leaching into these areas, however, post-development there will be many more potential contaminant sources. • Soils which will have been reused on-site will have been deemed as 'suitable for use' from an environmental and geotechnical point of view. • The risk of future contamination occurring (e.g. through spills and leaks etc.) will be minimised through good Environmental Management Practises and Procedures, monitoring and physical infrastructure (e.g. bunded tanks/containment areas, sealed drainage etc.).

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
area), WRAS • PAHs > ecological Stage 1 SSVs, Stage 2 and 3 background values and WRAS <u>Former NDA Spoil Disposal Area (Area 5)</u> • Asbestos • Cu, Zn, > ecological Stage 1 SSVs and Stage 2 and 3 background values • Zn, Cu > phytotoxic SSV • pH in excess of WRAS • Hydrocarbons >WRAS <u>Former Sewage Works (Area 6)</u> • Slightly elevated levels naturally occurring radioactivity associated with granite ballast • pH in excess of WRAS • Sulphate in excess of WRAS and BRE threshold • Boron in excess of phytotoxicity SSV • Benzo(a)pyrene and total PAH (TE63 ES2) > human health SSVs • Benzo(a)pyrene, anthracene, benzo(a)anthracene, indeno(123-cd)pyrene, total	• Phytotoxic risk to vegetation via plant uptake (3) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via Agricultural Drainage Ditches/Bristol Channel (6) • Air/wind transport (on-site and off-site) (8) • Predation and bioaccumulation (9)	<u>Non-Designated Ecological Systems</u> • Flora and fauna on-site • Flora and fauna off-site	**<u>Current Land Use. Baseline (Before Enabling/Remedial Works)</u>** **Potential soil linkage identified/Generally negligible risk with low to moderate risk in hotspots.** • In general the concentrations of potentially ecotoxic and phytotoxic contaminants in the soils on the BDAE, BDAW and SCPA are very low and consistent with rural England background concentrations and are not therefore considered to pose a significant ecological risk. A slightly higher, but still low risk is posed to ecological systems in some areas of the site due to the presence of slightly elevated concentrations of some potentially ecotoxic and phytotoxic heavy metals, PAHs, TPH and elevated pH mainly in some areas of the Made Ground on the BDAE but also to a lesser extent with isolated pockets of Made Ground on the BDAW and SCPA, and also in some natural soils. The localised zone of significantly hydrocarbon impacted Made Ground within Area 4 (TE418 vicinity) poses a moderate ecological risk, although this area is currently covered over and therefore less accessible to plants and animals. • Detailed ecological surveys on the have not reported any evidence of ecological impact that may be attributable to existing soil contamination.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
PAHs > ecological SSVs and Stage 2 and 3 background values (TE63 ES2) • Asbestos • Hydrocarbons > WRAS for TE63 **BDAW** • Heavy Metals – As, Cd, Cr, Ni, Se, Zn etc (in natural ground > Stage 1 ecological SSVs but generally below Stage 2 SSVs (i.e. rural England background) • Water soluble boron (Made Ground in TRE01 only) > phytotoxicity criteria • Zn > Tier 1 Phytotoxicity criteria (TRE01 and TRE21 Made Ground) • As > WRAS but < WWSSG • Occasional elevated Cd in natural ground > WRAS. • Elevated SO4 > WRAS and BRE screening criteria (WS85 and WS86) **SCPA** • Heavy Metals - Cd, Ni (in natural ground sample WS714 ES4) > ecological SSVs and Stage 2 and 3 background values • Water soluble boron (alluvial	• Phytotoxic risk to vegetation via plant uptake (3) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/ migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air / wind transport (on-site and off-site) (8) • Predation and bioaccumulation (9)	<u>Non Designated Ecological Systems</u> • Flora and fauna on-site (limited remaining flora and fauna during construction phase) • Flora and fauna offsite	<u>**Construction Phase (Post Enabling /Remedial Works)**</u> **Linkage unlikely. Very low to low risk.** • Zone of significant hydrocarbon contamination in vicinity of TE418 in Area 4 of the BDAE will have been removed. • Also, by the time any earthworks/construction works takes place, any sensitive plants and animals will have been removed/translocated (where necessary) as part of environmental mitigation works. • Any additional contamination identified during the earthworks /construction will be assessed to determine the potential risks posed, and subsequently removed and/or remediated as required. • Soil material proposed for re-use will be further analysed and assessed during earthworks to determine if 'suitable for use' from an environmental point of view as part of the Materials Management Plan and Soil Management Plan. Soils with significant exceedence of Stage 1 ecological or phytological SSVs and background concentrations can be mitigated by careful management in the selection and placement in less sensitive areas and not within the top 1m in areas of soft landscaping or agricultural restoration or ecological mitigation areas. • Any contaminated soils (within acceptability standards) that will have been reused on-site will have been carefully managed by the suitable placement of these materials beneath buildings and areas of hardstanding, and if placed in areas of soft landscaping, agricultural restoration or habitat creation these should not be placed within the upper 1.0m of the soil profile • Risk of mobilising contamination/pollution incidents is always increased during major earthworks/construction, however good environmental construction practice/Environmental/Pollution Prevention Management Plans will detail procedures to minimise these risks.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
peat in WS713 only) > phytotoxicity criteria • Slightly elevated pH > WRAS criteria • Elevated SO4 > WRAS and BRE screening criteria • Elevated VOCs (DBH2_13 only) by field PID testing (not validated by laboratory testing) Other potential sources on BDAW and SCPA. <u>Arable Crop Management</u> • Nitrates • Pesticides • Herbicides • Heavy metals • Metals and Metalloids <u>Agricultural vehicle maintenance and use</u> • Hydrocarbons • PAHs <u>Sewage Sludge Application</u> • Heavy Metals • Metals and Metalloids	• Phytotoxic risk to vegetation via plant uptake (3) • Inhalation of soils vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure (4) • Leaching/migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via agricultural drainage ditches/Bristol Channel (6) • Air/wind transport (on-site and off-site) (8) • Predation and bioaccumulation (9)	<u>Non Designated Ecological Systems</u> • Flora and fauna on-site (limited during operational phase on BDAW and BDAE) • Flora and fauna on-site (particularly in agricultural and ecological restoration areas on SCPA) • Flora and fauna off-site	**<u>Operational Phase (Commercial Land Use in BDAW / BDAE only. SCPA will be agricultural / habitat restoration areas)</u>** **Linkage unlikely to exist post development. Very low risk** • There will be very limited non designated ecological receptors post-development on the BDAW and BDAE area as the majority of the site will comprise buildings and hardstanding. However the SCPA will have significant non designated ecological receptors as significant parts of this area will be restored to agricultural land use and ecological habitat. • Post-development, the majority of the main development area will be covered by buildings and hardstanding, thus preventing exposure pathways of direct contact and ingestion. Also post-development, the majority of developed area will be hardstanding and buildings thus potential for presence of plants and animals in these areas will be low. • Soils which will have been reused on-site will have been 'suitable for use' from an environmental and geotechnical point of view. Soils with significant exceedence of Stage 1 ecological or phytological SSVs and background concentrations will have been controlled by careful management in the selection and placement in ecologically less sensitive areas (e.g. beneath buildings and hardstanding) and not within the top 1m in areas of soft landscaping or agricultural restoration or ecological mitigation areas. • Post-development, there will be many more potential contaminant sources. However, the risk of future contamination occurring (e.g. through spills and leaks etc.) will be minimised through good Environmental Management Practises and Procedures, monitoring and physical infrastructure (e.g. bunded tanks/containment areas, sealed drainage etc.).

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
Derelict Farm Buildings • Hydrocarbons • PAHs • Pesticides • Herbicides • Asbestos Infilled Ponds • Heavy Metals • Hydrocarbons • PAHs • Ground Gases • Asbestos **Potential Off-site Sources** Hinkley Point Power Station Complex • Hydrocarbons • PAHs • Solvents • PCB • Asbestos • Radioactive materials	• Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Phytotoxic risk to vegetation via plant uptake (3) • Leaching / Migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (8) • Migration of contaminants via Agricultural Drainage Ditches/Bristol Channel (6) • Air/wind transport (on and off-site) (8) • Predation and bioaccumulation (9)	Ecological Designations and Sensitive Land Uses • On-site County Wildlife Site • Off-site SSSI sites • Off-site NNR sites • Off-site SPA sites • On-site/off-site Nitrate Vulnerable Zone • Off-site RAMSAR site • Off-site SAC	**Current Land Use. Baseline (Before Enabling/Remedial Works)** **Potential soil linkage identified. Generally negligible risk with low to moderate risk in hotspots.** • There are no statutory designated ecological sites on the BDAE/BDAW or SCPA, however there are a number of ecological designations and sensitive land uses in off site adjacent areas, and the BDAE is listed as a (non-statutory) County Wildlife Site. • In general the concentrations of potentially ecotoxic and phytotoxic contaminants in the soils on the BDAE, BDAW and SCPA are very low and consistent with rural England background concentrations and are not therefore considered to pose a significant ecological risk. A slightly higher, but still low risk is posed to ecological systems in some areas of the site due to the presence of slightly elevated concentrations of some potentially ecotoxic and phytotoxic heavy metals, PAHs, TPH and elevated pH mainly in some areas of the Made Ground on the BDAE but also to a lesser extent with isolated pockets of Made Ground on the BDAW and SCPA, and also in some natural soils. The localised zone of significantly hydrocarbon impacted Made Ground within Area 4 (TE418 vicinity) poses a moderate ecological risk, although this area is currently covered over and therefore less accessible to plants and animals. • Detailed ecological surveys on the have not reported any evidence of ecological impact that may be attributable to existing soil contamination.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
Lime Kilns • Hydrocarbons • PAHs • Heavy Metals Alluvial deposits (salt marshland at Wick Moor and North Moor) Ground gases	• Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Phytotoxic risk to vegetation via plant uptake (3) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via Agricultural Drainage Ditches / Bristol Channel (6) • Air/wind transport (on-site and off-site) (8) • Predation and bioaccumulation (9)	Ecological Designations and Sensitive Land Uses • Off-site SSSI sites • Off-site NNR sites • Off-site SPA sites • On-site / off-site Nitrate Vulnerable Zone • Off-site RAMSAR site • Off-site SAC	**Construction Phase (Post Enabling /Remedial Works)** **Linkage unlikely. Very low to low risk.** • Zone of significant hydrocarbon contamination in vicinity of TE418 in Area 4 of the BDAE will have been removed. • Also, by the time any earthworks/construction works takes place, any sensitive plants and animals will have been removed/translocated (where necessary) as part of environmental mitigation works. • Any additional contamination identified during the earthworks/construction will be assessed to determine the potential risks posed, and subsequently removed and/or remediated as required. • Soil material proposed for re-use will be further analysed and assessed during earthworks to determine if 'suitable for use' from an environmental point of view as part of the Materials Management Plan and Soil Management Plan. Risk from soils with significant exceedance of Stage 1 ecological or phytological SSVs and background concentrations can be controlled by careful management in the selection and placement in less sensitive areas and not within the top 1m in areas of soft landscaping or agricultural restoration or ecological mitigation areas • Any contaminated soils (within acceptability standards) that will have been reused on site will have been carefully managed by the suitable placement of these materials beneath buildings and areas of hardstanding, and if placed in areas of soft landscaping, agricultural restoration or habitat creation these should not be placed within the upper 1.0 m of the soil profile • Risk of mobilising contamination/pollution incidents is always increased during major earthworks/construction, however good environmental construction practice/Environmental/Pollution Prevention Management Plans will detail procedures to minimise these risks.

Potential Source(s)	Potential Pathways/ Exposure Mechanisms	Potential Receptors	Relevant Pollutant Linkage Present?/Initial Risk Level Comments and Risk Control Measures
	• Migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes) (2) • Phytotoxic risk to vegetation via plant uptake (3) • Leaching/Migration via permeable ground (5) • Transfer of contaminants via surface run-off (6) • Transfer of contaminants via groundwater (7) • Inhalation of vapours from groundwater (4) • Migration of contaminants via agricultural drainage ditches / Bristol Channel (6) • Air/wind transport (on-site and off-site) (8) • Predation and bioaccumulation (9)	Ecological Designations and Sensitive Land Uses • Off-site SSSI sites • Off-site NNR sites • Off-site SPA sites • On-site/off-site Nitrate Vulnerable Zone • Off-site RAMSAR site • Off-site SAC	**Operational Phase (Commercial Land Use in BDAW / BDAE only. SCPA will be agricultural / habitat restoration areas)** **Linkage unlikely to exist post-development. Very low risk** • There will be no designated ecological receptors post-development on the BDAW and BDAE area as the majority of the site will comprise buildings and hardstanding. • Post-development, the majority of the main development area will be covered by buildings and hardstanding, thus preventing exposure pathways of direct contact and ingestion. • Soils which will have been reused on site will have been 'suitable for use' from an environmental and geotechnical point of view. Soils with significant exceedance of Stage 1 ecotoxicological or phytotoxicolgical SSVs and background concentrations will have been controlled by careful management in the selection and placement in ecologically less sensitive areas (e.g. beneath buildings and hardstanding) and not within the top 1m in areas of soft landscaping or agricultural restoration or ecological mitigation areas • Post-development, there will be many more potential contaminant sources. However, the risk of future contamination occurring (e.g. through spills and leaks etc) will be minimised through good Environmental Management Practises and Procedures, monitoring and physical infrastructure (e.g. bunded tanks/containment areas, sealed drainage etc).

APPENDIX 15A: PUMPING TEST ANALYSES

[This page is intentionally left blank]

Pumping Tests from PW-1 at Hinkley C

1. Summary

The July-August 2010 pumping test conducted on PW-1 at the Hinkley Point C site has been re-analysed. Table 1.1 summarises the analysis methods applied and the results.

This short technical note summarises the analysis conducted.

Table 1.1 Summary of analyses and results.

Method and data	Transmissivity (m2/s)	Storage coefficient [-]
Cooper-Jacob, early time. All Piezometers	1.9×10^{-3} to 8.0×10^{-4}	2×10^{-2} to 6×10^{-5}
Distance –drawdown, 12, 24, 48 and 96 hours	1.0×10^{-3} to 7.1×10^{-4}	9×10^{-4} to 2×10^{-7}
Theis recovery	1.3×10^{-3} to 1.8×10^{-3}	n/a

Note these values are based on manual rather than automated analysis.
Values of storage below 10^{-6} are not taken to be realistic.

Only the constant rate data was analysed. The following points and conclusions are drawn:

1. The constant rate test and data obtained are of medium quality. The pumping rate did vary significantly through the test, reducing from 3.07 to 2.11 l/s;
2. There is a very large drawdown in the pumped well by the end of the test, with apparently less than 0.5 m of water remaining in the pumped well. It is surprising that it was possible to maintain a 2 l/s of yield to the end of the test;
3. The system displays some degree of anisotropy. Distance-drawdown analysis shows horizontal anisotropy with T_{E-W} :T_{N-S} ratio of ~1.3:1. This is less than the 2:1 found when analysing the July 2010 pumping test of PW-2;
4. Cooper-Jacob analysis again indicates the presence of a barrier or transition to lower permeability in the aquifer. The deviation from straight line behaviour occurs at around 5,000 seconds, earlier than the 40,000 seconds observed in the PW2 test. It is interpreted that the barrier is closer to PW1 than PW2;
5. The recovery analysis shows unconfined behaviour due to dewatering of the aquifer around the pumped well. Storage values from the recovery are unfortunately unreliable.

2. Constant Rate Test

The constant rate test lasted 4 days exactly, from 08:00 30th July to 08:00 3rd August 2010. The desired pumping rate was 3.0 l/s with records taken manually using totalising and electromagnetic flow meters. The recorded abstraction declined over the test, from 3.03 l/s to 2.1 l/s. The decline in rate is seen as a decrease in gradient at late times in Cooper-Jacob plots, beyond ~ 2 days (170,000 seconds).

Water levels in the pumping well decline to 21m below datum, effectively the bottom of the hole and account for the decline in yield. The water level at the start of the test (3.8-4.0 m BD) coincides with the top of the siltstone sequence of the Blue Lias beds.

2.1 Cooper Jacob Analysis

Results of Cooper-Jacob analysis of early times, from approximately 600 to 6000 seconds (10-100 minutes) are given in Table 2.1.

Table 2.1 Transmissivity and Storage values for early time based on manual fit.

Observation Well	T (m2/s)	T (m2/d)	S [-]
PZ01	9.6E-04	83	1.4E-04
PZ02	8.6E-04	74	2.4E-04
PZ03	8.0E-04	69	6.7E-04
PZ04	8.0E-04	69	7.0E-05
PZ05	9.5E-04	82	6.0E-05
PZ06	8.2E-04	71	1.2E-04
PZ07	9.1E-04	79	5.0E-04
PZ08	1.1E-03	99	1.2E-03
PZ09	8.0E-04	69	1.8E-02
PZ10	9.2E-04	79	3.5E-03
PZ12	1.9E-03	163	1.2E-03
Maximum	**1.9E-03**	**163**	**1.8E-02**
Minimum	**8.0E-04**	**69**	**6.0E-05**
Average	**9.8E-04**	**85**	**2.3E-03**

2.2 Distance drawdown analysis

Distance drawdown analysis has been completed at 4 times during the constant rate test:

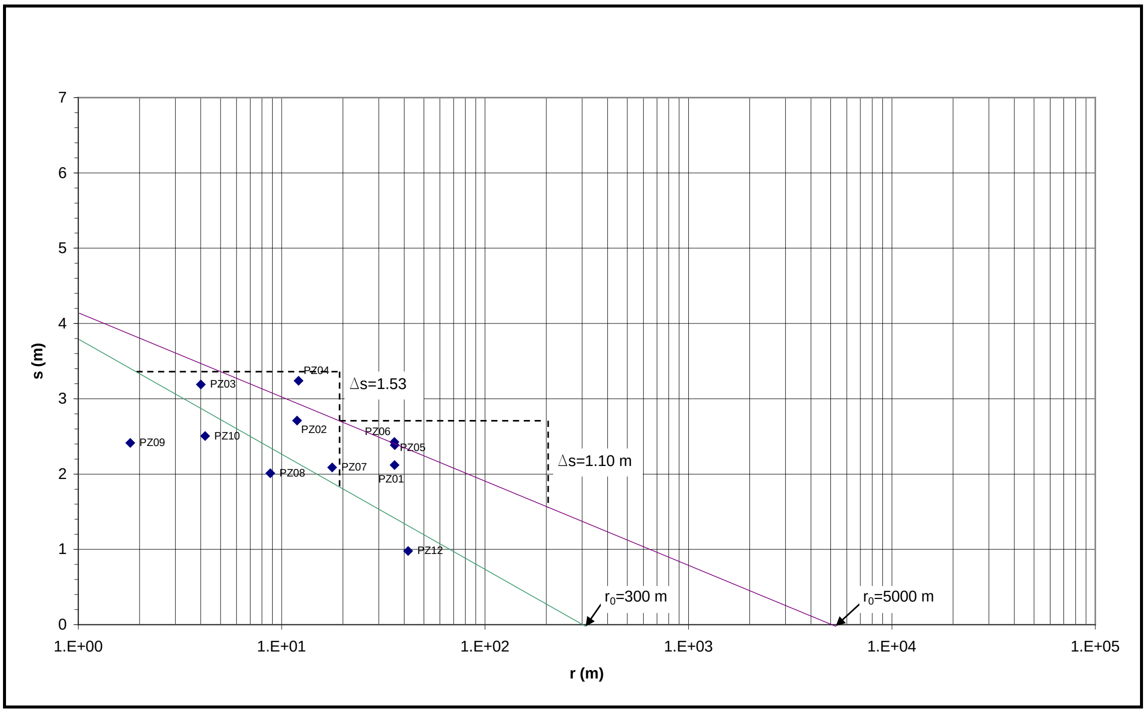
- 43,200 seconds, 12 hours;
- 86,400 seconds, 24 hours;
- 172,800 seconds, 48 hours; and,
- 345,600 seconds, 96 hours.

Figures 2.1 to 2.4 present the distance-drawdown analysis. The analysis has considered two groups of boreholes:

- A north-south orientated group consisting of: PZ08, PZ10 and PZ12; and
- An east-west orientated group consisting of: PZ01, PZ02, PZ03, and PZ05.

The other piezometers PZ04, PZ06, PZ07 and PZ09 tend to lie slightly or further off the main trend lines.

Figure 2-1 Distance-Drawdown plot 12 hours into test (t=43,200 seconds).



Note greater drawdown in E-W compared to N-S group indicating anisotropy.

Figure 2-2 Distance-Drawdown plot 24 hours into test (t=86,400 sec).

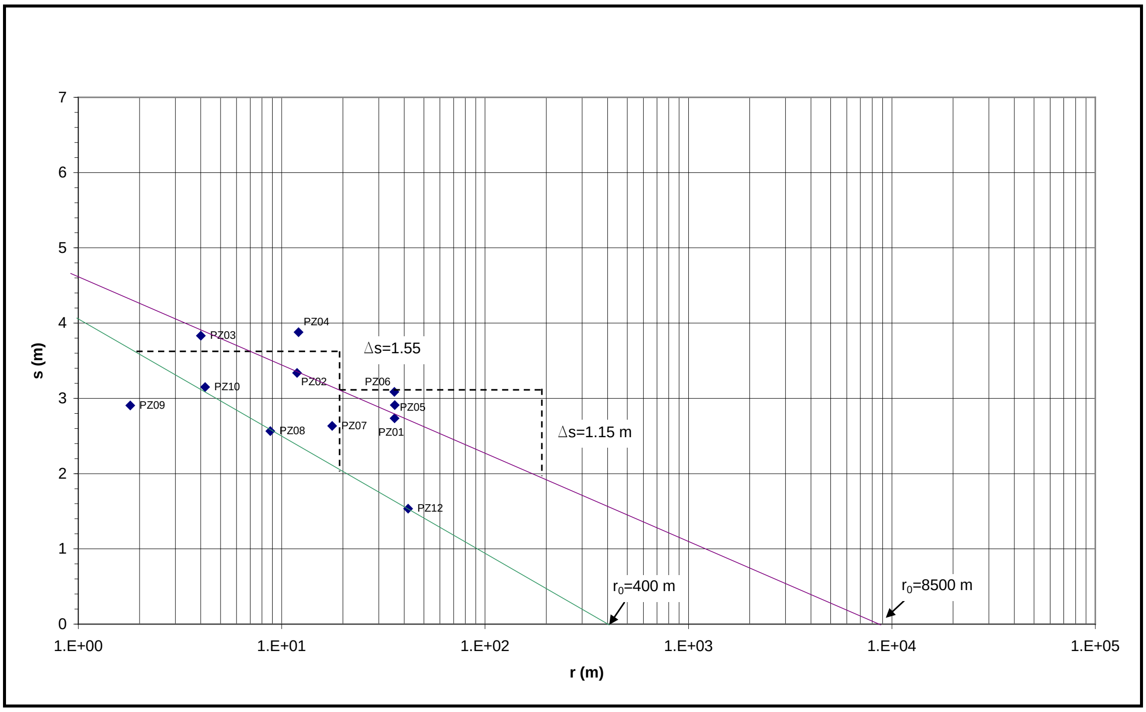


Figure 2-3 Distance-Drawdown plot 48 hours into test (t=172,800 sec).

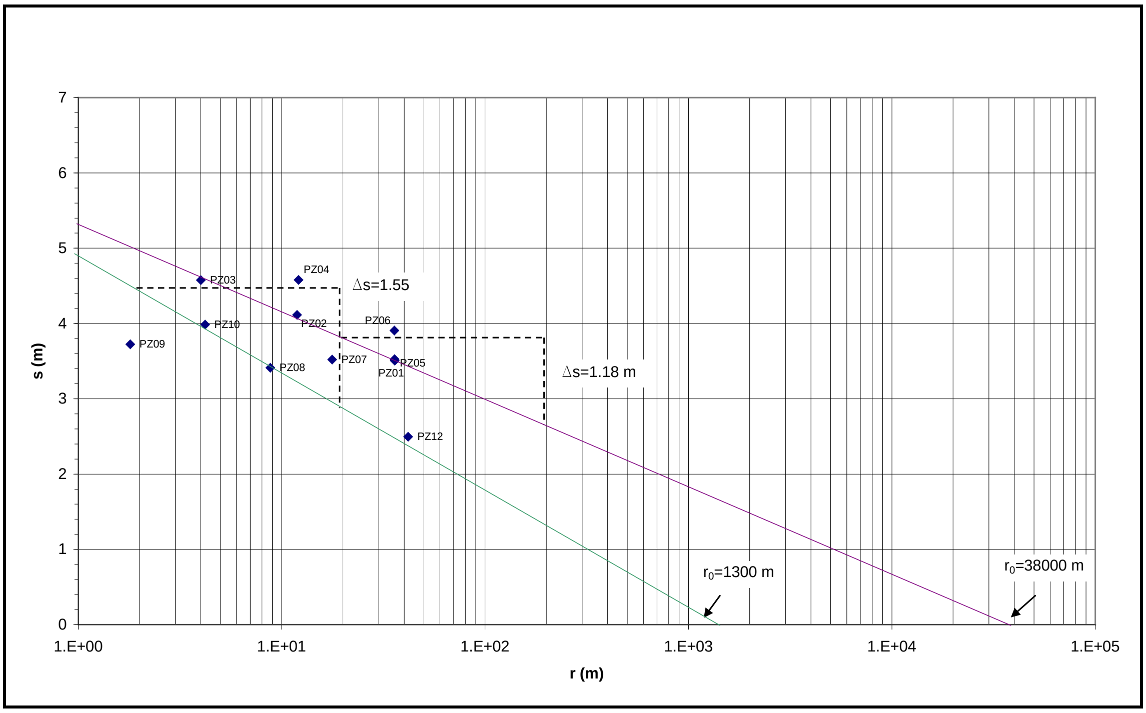

Figure 2-4 Distance-Drawdown plot 96 hours into test (t=345,600 sec).

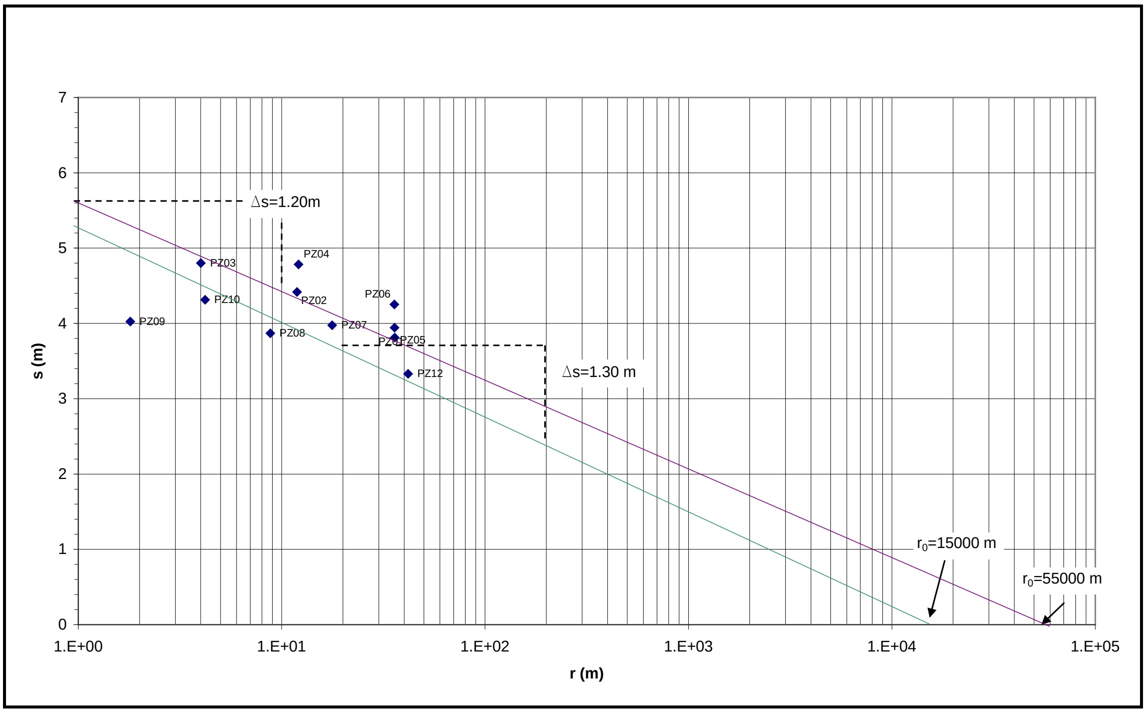


Results of the analysis are summarised in Table 2.2.

Table 2.2 Distance Drawdown Analysis Results

	N-S Group	
Time, seconds	**Transmissivity (m^2/s)**	**Storage coefficient**
43,200	7.2E-04	7.8E-04
86,400	7.1E-04	8.6E-04
172,800	7.1E-04	1.6E-04
345,600	8.4E-04	2.9E-06
	E-W Group	
Time, seconds	**Transmissivity (m^2/s)**	**Storage coefficient**
43,200	1.0E-03	3.9E-06
86,400	9.5E-04	2.6E-06
172,800	9.3E-04	2.5E-07
345,600	9.2E-04	2.4E-07

The N-S group has an average transmissivity of $7.4x10^{-4}$, whilst the E-W group is $9.5x10^{-4}$. This shows evidence of horizontal anisotropy in the formation with T_{E-W}:T_{N-S} ratio of 1.3:1.

The storage coefficients derived by the distance drawdown method are extremely sensitive to the intercept of the fitted straight line. Therefore, little account is taken of storage estimates from this method.

3. Recovery test

Theis recovery analysis was conducted on 2 of the piezometers: PZ01 and PZ10. The initial recovery shows some straight line behaviour but recovery is very slow. Values of storage coefficient ratio taken from this early time are extremely low, which in turn gives storage values greater than 1. This indicates that some of the assumptions made for the analysis are not valid, such as the aquifer being confined.

Table 3.1 Summary of Theis Recovery analysis

	Manual analysis (early time)	
Piezometer	**Transmissivity (m^2/s)**	**Storage coefficient ratio**
PZ01	0.0018	1.8e-10
PZ10	0.0013	1.69e-7

4. Further interpretation

The response to pumping beyond around 5,000 seconds (~1.4 hours) shows increasing drawdown with log time. Under the Cooper-Jacob analysis this is interpreted as a boundary effect.

In the recovery analysis there is a strong suggestion that the test is providing an unconfined response. It is also the case that the pumped well is nearly dewatered during the test, to within only 0.5m of the base of the well.

Pumping Tests from PW2-1 at Hinkley C

1. Summary

The July 2010 pumping tests conducted from PW2-1 at the Hinkley Point C site have been analysed. Table 1.1 summarises the analysis methods applied and the results.

Table 1.1 Summary of analyses and results.

Method and data	Transmissivity (m2/s)	Storage coefficient [-]
Theis, PZ2-1 only	2.1×10^{-4}	3×10^{-5}
Cooper-Jacob, mid time. All Piezometers	2.0×10^{-4} to 3.0×10^{-4}	2×10^{-3} to 1×10^{-5}
Distance –drawdown, 12, 24, 48 and 96 hours	2.4×10^{-4} to 5.3×10^{-4}	3×10^{-4} to 2×10^{-11}
Theis recovery	2.1×10^{-4} to 7.5×10^{-4}	0.04[1] to 5×10^{-4}

Note these values are based on manual rather than automated analysis.
Values of storage below 10^{-6} are not taken to be realistic. [1] 0.04 represents an unconfined specific yield.

From the analysis the following conclusions are drawn:

1. The step test was conducted with recovery periods between steps. Normally steps are performed in succession with no break in pumping or recovery;

2. The constant rate test and data obtained are of a relatively high quality. Pumping rate did vary through the test, but only by ~4%;

3. During pumping phases, the responses at the observation piezometers do not show the influences of the dewatering of the aquifer around the pumped well;

4. The system is anisotropic. Distance-drawdown analysis shows horizontal anisotropy to be present with horizontal anisotropy in the formation with a $T_{E-W}:T_{N-S}$ ratio of ~2:1;

5. A barrier is present within the aquifer that acts to significantly reduce permeability. It is difficult to be precise in the distance and direction of the boundary, but calculations indicate an approximate distance of 400-600 m. The nature of the boundary is unknown, but it could be related to thinning of the formation to the south, indicate a fault or be related to other structures on the Hinkley site;

6. The recovery analysis shows unconfined behaviour due to dewatering of the aquifer around the pumped well. Storage values from the recovery are typically an order of magnitude, or more, greater than those derived from consideration of the pumped phase; and

7. Estimates of storage co-efficient vary widely, depending on analysis technique and the data used. The long term storage of an aquifer is usually only revealed by longer term pumping. It is, therefore, suggested that the higher values calculated from the recovery phase, 0.04 are adopted for further calculations and modelling, and that larger values will likely be found under longer term dewatering.

2. Introduction

The testing and monitoring were conducted by Stuart Well Services Ltd. The interpretation presented here is based on the following information received from EDF:

- Stuart Well Services Ltd report No.SWC4399/1, September 2010 (10986 page file Pumping Testing Report.pdf); and
- Electronic data files in Excel (.xlsx) and Acrobat (.pdf) format.

2.1 Schedule of tests

The testing scheduled comprised:

1. Initial set up and checking of pump, 8th to 12th July.
2. Step testing consisting of 4 steps. Steps 1 and 2 of 0.5 and 1 l/s were conducted on, 13th July for 100 minutes each with Steps 3 and 4 of 0.5 and 2.0 l/s conducted for 100 minutes on 14th July. Following step testing recovery was monitored prior to the constant rate test. Note that the pumped well was permitted to recovery during the step tests, with gaps of 2 hours 50 minutes between pumping Steps 1 and 2, and 3 hours 20 minutes between Steps 3 and 4;
3. The constant rate test at a nominal rate of 1.5 l/s lasted 4 days exactly, from 14:00 15th to 14:00 19th July 2010; and,
4. Manual recovery monitoring in the pumped and 12 piezometers continued for a further 4 days until 23rd July, with data loggers left in position to continue recording until 6th August, 18 days after pumping ceased.

The test analysis conducted in this document concentrates on the aquifer. For that reason the constant rate and recovery data are considered whilst the step test data are not.

3. Site description

The following description of the geology of the site is taken from Stuart Well Services Ltd report No.SWC4399/1, September 2010:

> *"Ground level ranges between 14.1 and 16.22mAOD. Geology is recorded as top soil and clay to between 12 to 14mAOD overlying layered mudstone siltstone with limestone bands that extends to the base of all test wells.*
>
> *The site geology has been extensively investigated in previous investigations. It is known that the Hinkley site is underlain by layered mudstone siltstone with limestone bands which have been identified as the Blue Lias formation. The*

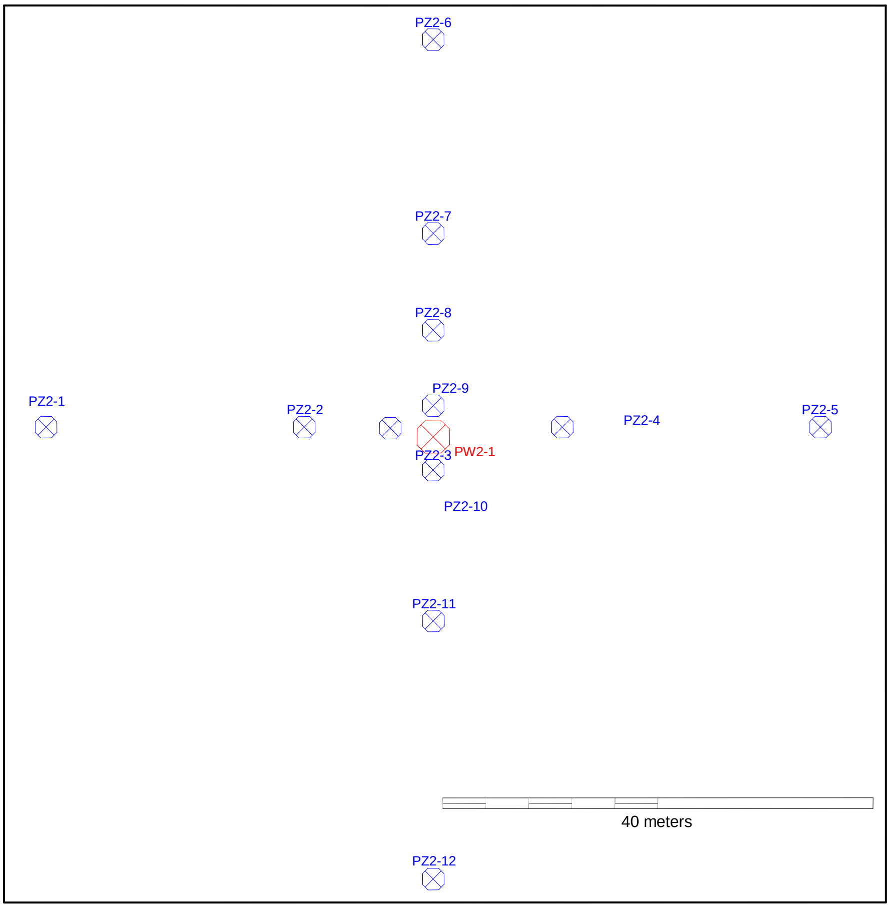
Blue Lias Formation is thinnest at the south of the site, approximately 10m thick. The formation base dips by about 10o to the north where it is approximately 65m. Underlying the the Blue Lias is the Penarth Group (Laminated limestone mudstone) of about 13m thickness that overlies the Blue Anchor Formation (Grey to green siltstone mudstone) which extends to approximately 120mBGL before the Red Mudstone Formation is encountered (Green to red siltstones and mudstones).

This report will refer to the upper layered mudstone siltstone as the Blue Lias to maintain continuity with previous investigative reports. All wells were therefore screened within the Blue Lias Formation. Where wells penetrated the underlying Penarth Group or Blue Anchor we understand that these wells were backfilled with bentonite grout up to the base of the screened section permitting only testing within the Blue Lias Formation."

3.1 Pumped and monitoring wells

Figure 3.1 shows the layout of the pumped well PW2-1 and the 12 piezometers arranged in north-south and east-west orientations.

Figure 3-1 Basic site layout of pumped well and piezometers



3.2 Antecedent and Meteorological conditions

Ideally groundwater levels are monitored for a number of days or weeks prior to testing to reveal any temporal trends in levels. Levels (below datum) are presented in Figure 3.2 for piezometer PZ2-1 for the 12 days prior to installation and initial testing of the pump on 12th July. This shows some trends for the aquifer, but with fluctuations of the order of 0.05 m, it is felt that there is no need to correct observed data for large scale temporal trends.

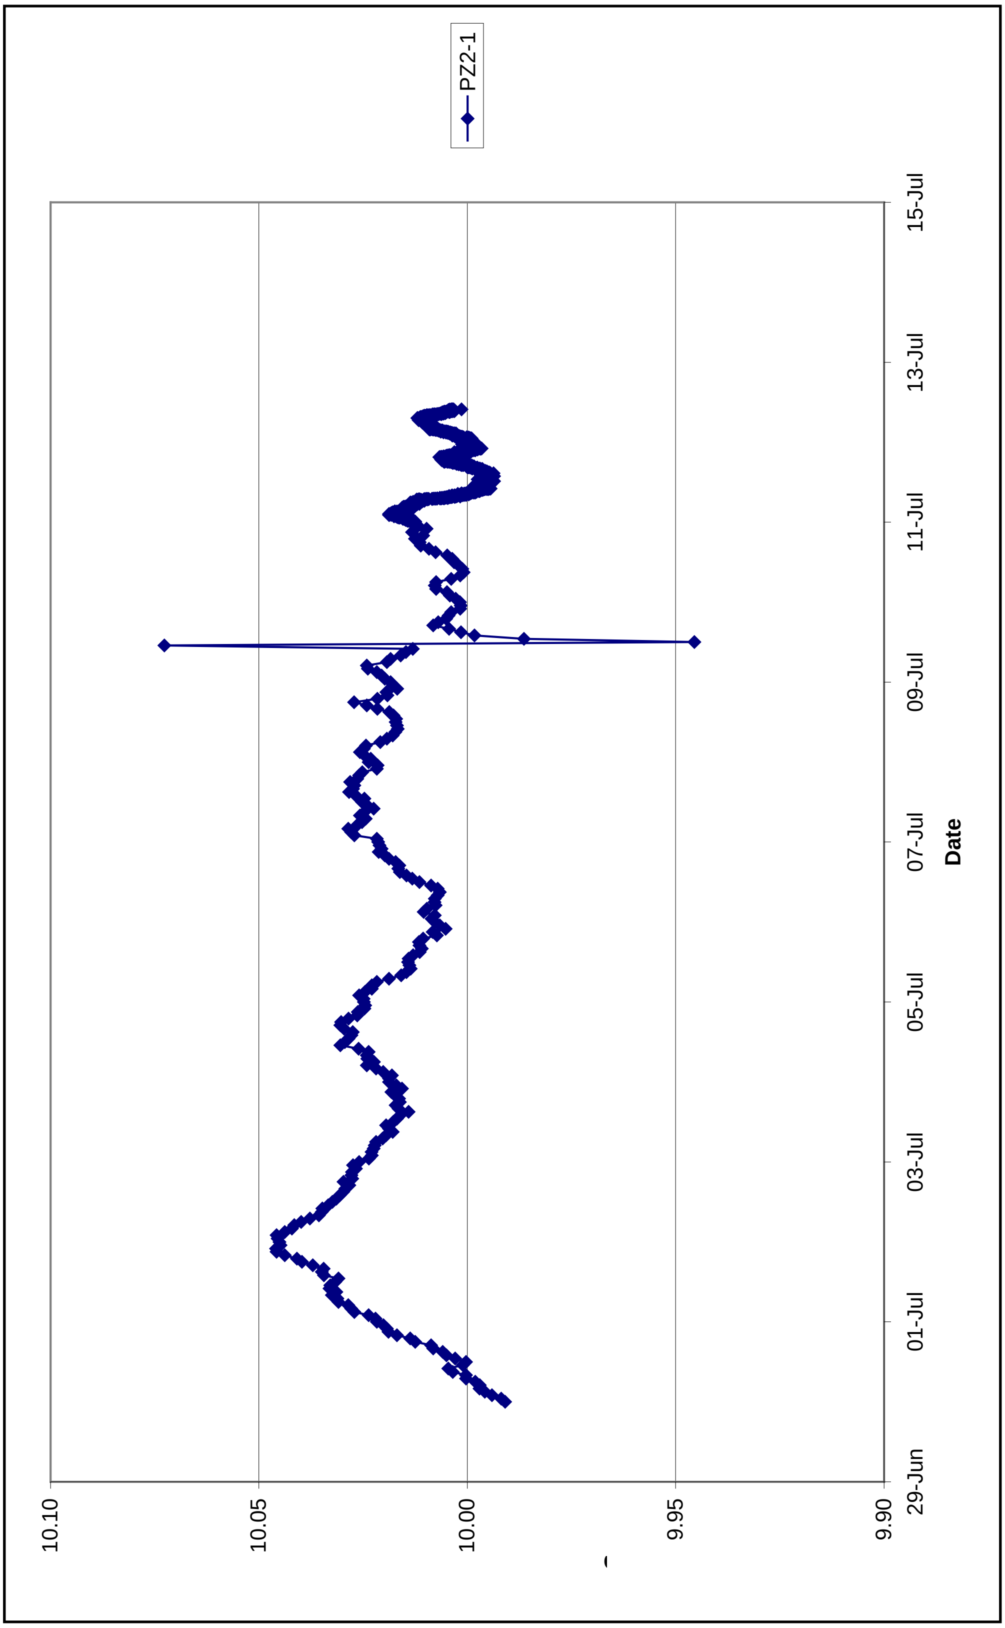
Rainfall during the test was recorded by SWS and is presented in Table 3.1 for the period 12/07/2010 – 23/07/2010.

Table 3.1 Rainfall recorded during pumping test. Readings are for 24 hour periods, 10:00am to 10:00am.

Date	Rainfall (mm)	Date	Rainfall (mm)
12/07/2010 to 13/07/2010	1.8	18/07/2010 to 19/07/2010	0
13/07/2010 to 14/07/2010	1.7	19/07/2010 to 20/07/2010	3
14/07/2010 to 15/07/2010	5	20/07/2010 to 21/07/2010	8.6
15/07/2010 to 16/07/2010	5.5	21/07/2010 to 22/07/2010	2
16/07/2010 to 17/07/2010	6.5	22/07/2010 to 23/07/2010	0
17/07/2010 to 18/07/2010	0.5		

Note that the spike response on 9th July is related to the transducer / data logger being removed from the borehole.

Figure 3-2 Groundwater levels prior to testing in piezometer PZ2-1



4. Constant Rate Test

The constant rate test lasted 4 days exactly, from 14:00 15th to 14:00 19th July 2010. The desired pumping rate was 1.5 l/s with records taken manually using totalising and electromagnetic flow meters. The recorded abstraction is presented in Figure 4.1 and following points are made:

- Average pumping rate was 1.52 l/s;
- From 3300 seconds to 6000 seconds (55 to 100 minutes) flows rate increased to 1.57 l/s;
- Some significant variation in flow rate is observed from ~ 30,000 to 54,000 Seconds (550 to 900 minutes); and,
- Later in the test the pumping rate declines to 1.52 and 1.51 l/s.

Whilst these variations appear minor, they do influence the recorded drawdown in the observation piezometers.

Figure 4.2 presents the water level recorded in the pumped well during the step and constant rate tests. This figure shows that recovery from the step testing on 13th and 14th July was not fully complete. However, the overall recovery from the step tests is ~99% with a residual drawdown of 0.12m at the start of the constant rate test. This compares to a drawdown of 12.26 in the pumped well during the constant rate test, and 9.25 m during the last step of the step test. Due to the small residual, the constant rate data was not corrected.

The pumping well drawdown of 12.26 m takes water levels to 18 m below datum, and apparently only 2 m above the base of the borehole. Such a low level of water in the pumped well would normally cause issues such as cavitation, but no mention is made of such issues which may be due to the low flow rate. The water level at the start of the test (5.95m BD) is approximately 2m below the top of the siltstone sequence of the Blue Lias beds.

The test was monitored in the 12 piezometers listed in Table 3.1 using downhole pressure transducers and loggers. The data were corrected for barometric pressure by the testing contractor, and the analysis presented below uses pressure corrected data.

Additionally manual monitoring was conducted by SWS in the pumped well and piezometers. This data corroborates the logger data and is not analysed. It is presented in Appendix B the SWS report.

4.1 Theis analysis

Stuart Well Services completed analysis of data from all 12 piezometers using the Theis curve matching method, as presented in Figure 8 (report page 5932). The Theis analysis has been repeated for piezometer PZ2-1, located 35.98 m to the west of the pumped well. Figure 4.3 presents the Theis method curve for this piezometer and the hydraulic properties calculated are:

- Transmissivity of 2.1×10^{-4} m^2/s; and
- Confined storage coefficient of 3.4×10^{-5}.

Figure 4-1 Abstraction rate for constant rate test

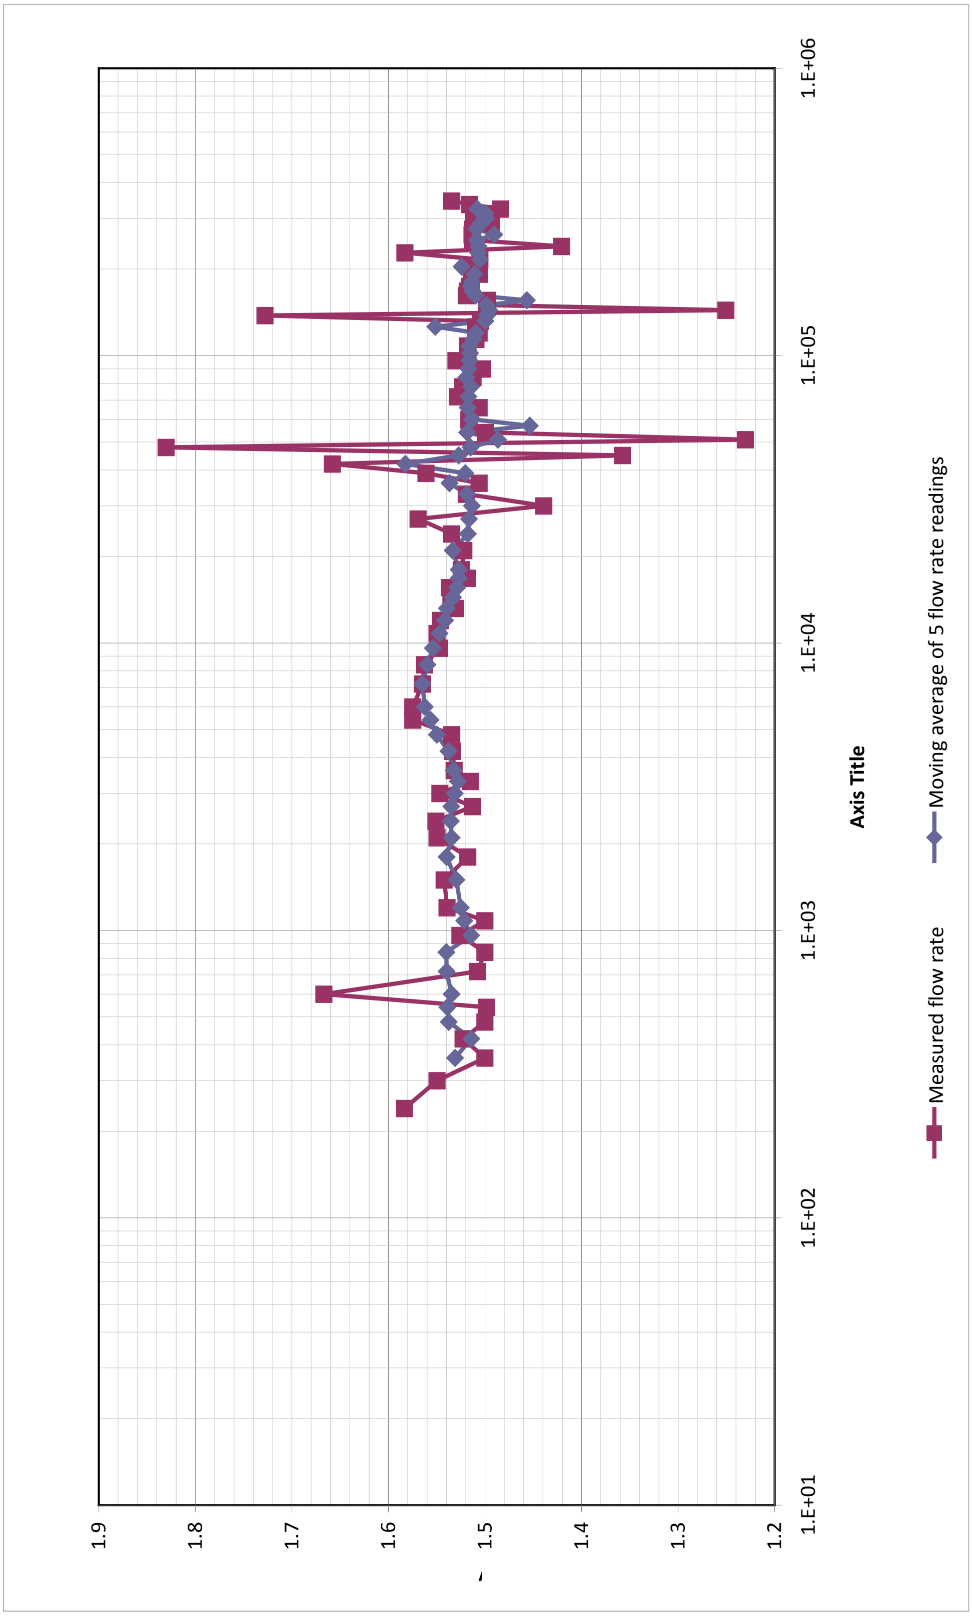


Figure 4-2 Water levels in the pumped well and flow rates for step and constant rate tests.

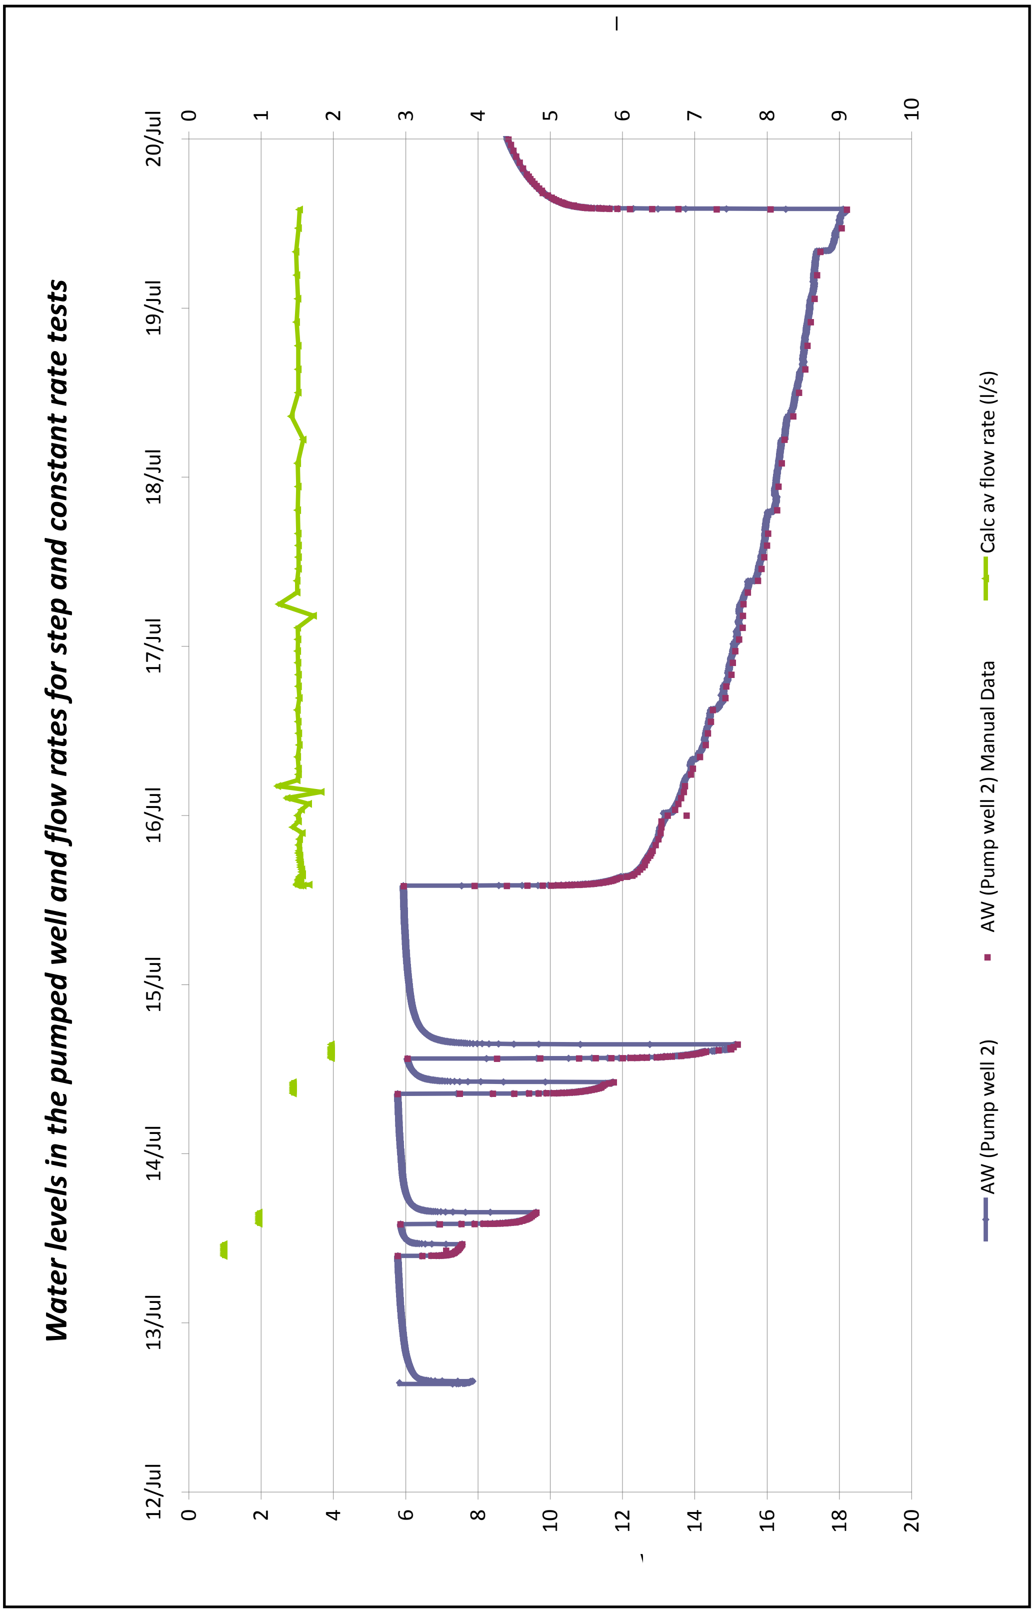

Figure 4-3 Theis analysis of data upto 40,000 seconds for PZ2-1.

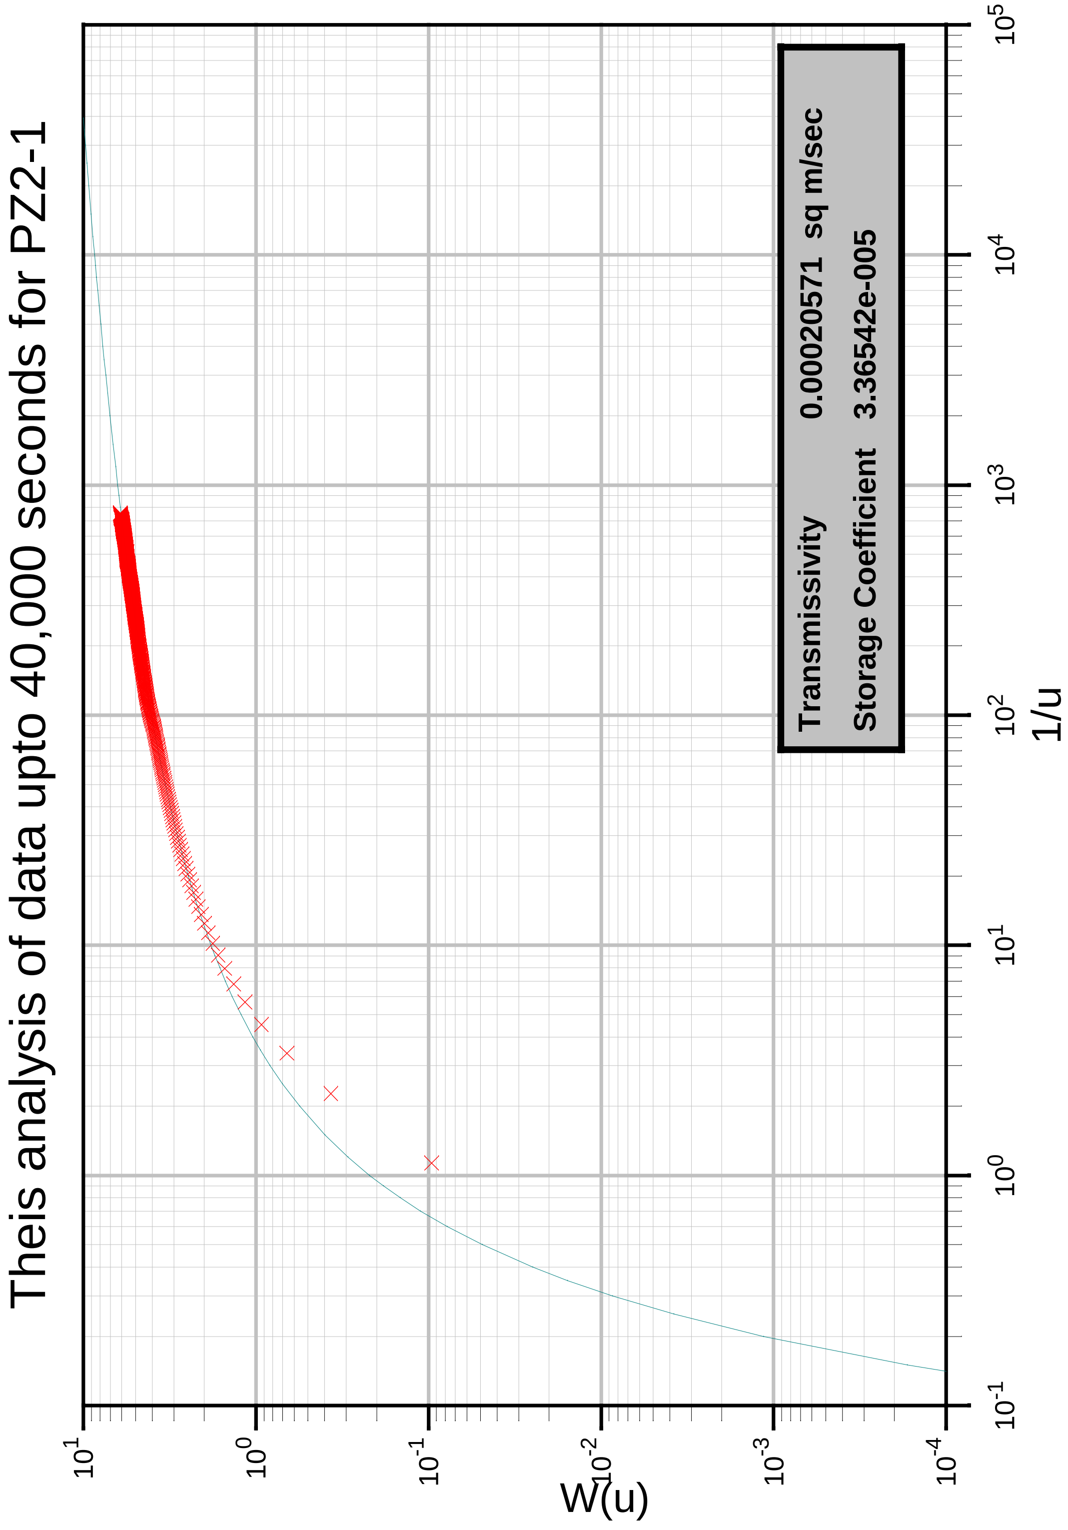

For the same Theis analysis and similar periods of data SWS calculated values of, 1.9 x 10^{-4} m^2/s and 4.5 x 10^{-5} respectively. The transmissivity results agree closely, with a larger difference between storage values. The discrepancy highlights the sensitivity of the Theis method to choice of curve fit, and the data used for the analysis, but the overall conclusion is that SWS have applied the Theis method without error.

There is a question mark regarding the assumption of a confined, fully saturated aquifer made in the Theis solution, which does not really apply at the start of the test and becomes less valid as drawdown increases. However, the response seen in the piezometers does not suggest that the partial dewatering is having a large effect on the test, particularly up to ~ 11 hrs, 40,000 seconds.

4.2 Cooper Jacob Analysis

The Cooper-Jacob semi-log analysis method follows the same assumptions as for the Theis. It uses an approximation that becomes more valid at later times. The level to which the approximation is valid can be calculated using parameter u, given by:

$$u = \frac{r^2 S}{4KDt}$$

where:

- r is the radial distance to the observation well;
- S is the dimensionless storage of the aquifer;
- K is the hydraulic conductivity;
- D the aquifer thickness; and,
- t, the time since commencement of pumping.

For values of $u<0.15$ the error introduced by the approximation is 10% and this declines to 1% for $u<0.03$ (Krusemann and de Ridder, 1990). The condition of u being small is usually satisfied relatively quickly in confined aquifers. It means that early time data needs to be treated with caution, but this information can also be affected by wellbore storage.

Cooper-Jacob analysis has been performed separately for all 12 observation piezometers. The analysis has been completed both with manual and automatic line fitting with Aquifer Win32 pumping test software, with figures presented in Appendix A. The manual line fitting took greatest account of the straight line section between approximately 500 and 40,000 seconds. Early time data was discounted due to the $u<0.03$ condition and the later time analysis due to clear deviation and increasing drawdown.

As an additional check, the test data from PZ2-1 has been analysed manually, drawing a straight line by hand and calculating transmissivity and storage values.

The trends observed in the piezometers follow a similar pattern of:

- early time response following an approximately straight line trend;
- at around 5,000 seconds (83 minutes) a slight kink of increased drawdown. From this straight line trend is re-established at a similar slope;

- at around 40,000 seconds (11 hours) a break from straight line behaviour occurs with an increasing trend in drawdown. This trend does not settle into a straight line, but continues as an increasing drawdown curve. Increasing drawdown at later time may be due to thinning of the aquifer to the south or a low permeability boundary.

Exceptions to this behaviour include:

- Piezometers PZ2-6 and PZ2-7 (36.93 and 18.90 m to the north of the pumped well) show different early time responses. Both start to respond to pumping later than other piezometers, at 800 and 1,000 seconds. PZ2-6 quickly settles to a straight line response, whilst PZ2-7 shows a cu rved response of rapidly increasing drawdown between 800 and 2,500 seconds.
- In piezometer PZ2-6 the switch from (log) linear response to an increasing drawdown appears to be slightly earlier at ~30,000 seconds;

The Cooper-Jacob plots do not show clear signs of the aquifer starting to move to unconfined behaviour. Given that piezometric levels are lowered to within the aquifer unit, there is the potential for an unconfined response, but if this is present, it is swamped by the influence of a boundary that becomes increasingly apparent from around 11 hours (40,000 seconds). A move to unconfined conditions would be expected to decrease the rate of drawdown as more water is released from storage close to the pumped well.

Table 4.1 and Table 4.2 list the results of the analysis for hydraulic parameters T and S based on an automatic fit and manual fit on early data respectively.

Table 4.1 Transmissivity and Storage values for observation wells based on an automatic fit.

PZ2-7	0.00020	17.3	0.00025
PZ2-8	0.00022	19.0	0.00033
PZ2-9	0.00020	17.3	0.00085
PZ2-10	0.00023	19.9	0.0020
PZ2-11	0.00027	23.3	0.00084
PZ2-12	0.00029	25.1	0.00030

The automated fit is biased to later times on the $\log_{10}$ simply due to the larger number of data points. The trend to increasing drawdown verses log-time indicates another influence within the aquifer that does not conform to the Theis / Cooper-Jacob assumptions. Therefore, the manual analysis of earlier time data is thought more reliable than the automated analysis biased towards later log-time.

With the manual calculations, Transmissivity values average 2.3×10^{-4} m^2/s. A calculation of the time at which U<0.15 for the nearest and furthest piezometers (PZ2-9 and PZ2-12) are 70 and 14,000 seconds respectively.

4.3 Distance drawdown analysis

Distance drawdown analysis has been completed at 4 times during the constant rate test:

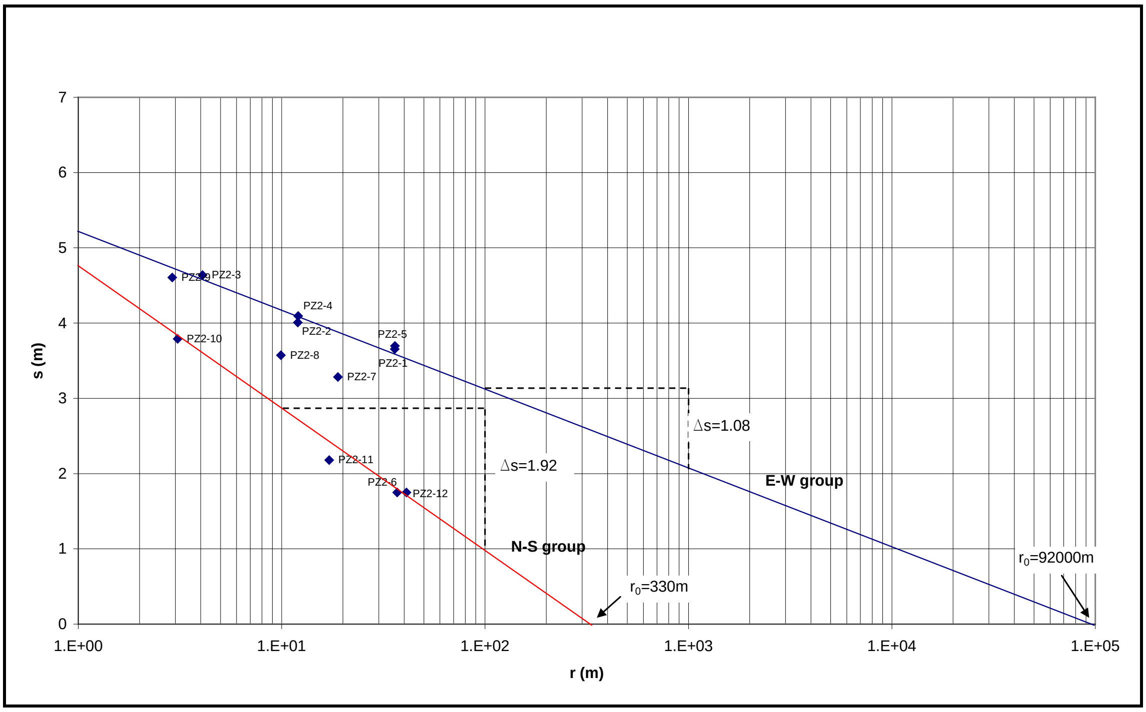
- 43,200 seconds, 12 hours;
- 86,400 seconds, 24 hours;
- 172,800 seconds, 48 hours; and
- 345,600 seconds, 96 hours.

Figures 4.4 to 4.7 present the distance-drawdown analysis. The analysis has considered two groups of boreholes:

- A north-south orientated group consisting of: PZ2-6, PZ2-10, PZ2-11 and PZ2-12; and
- An east-west orientated group consisting of: PZ2-1, PZ2-2, PZ2-3, PZ2-4, and PZ2-5.

The other piezometers PZ2-7, PZ2-8 and PZ2-9 show some anomalous behaviour and are not considered.

Figure 4-4 Distance-Drawdown plot 12 hours into test (t=43,200 seconds).



Note greater drawdown in E-W compared to N-S group indicating anisotropy.

Figure 4-5 Distance-Drawdown plot 24 hours into test (t=86,400 sec).

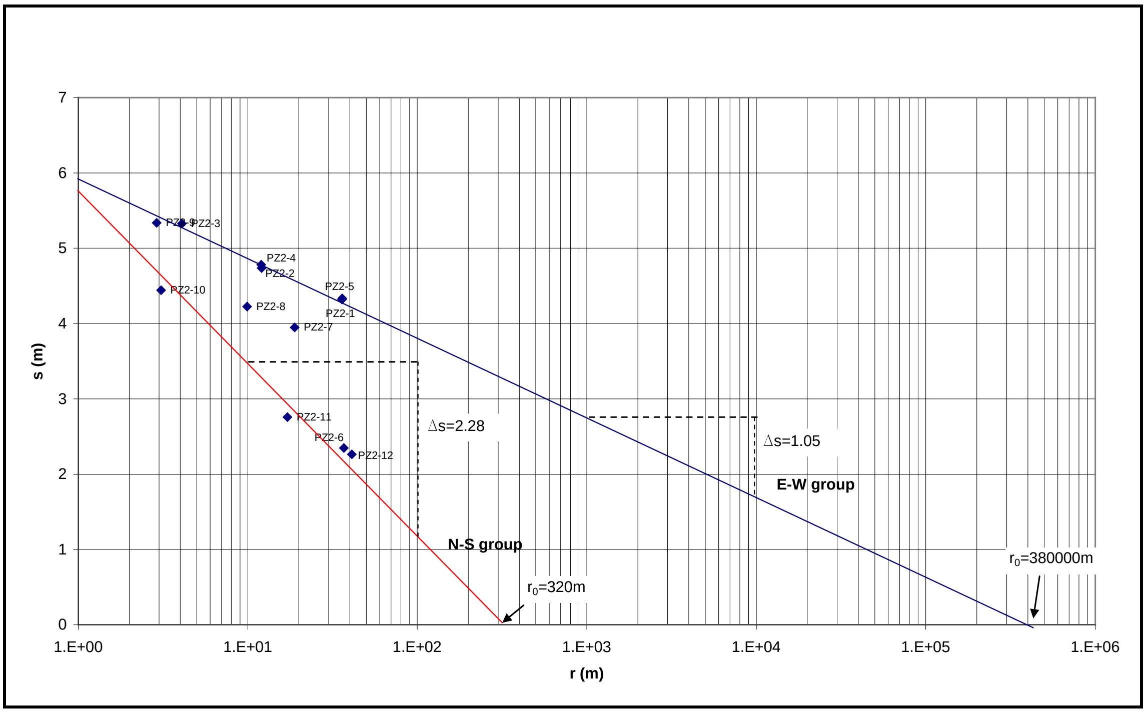


Figure 4-6 Distance-Drawdown plot 48 hours into test (t=172,800 sec).

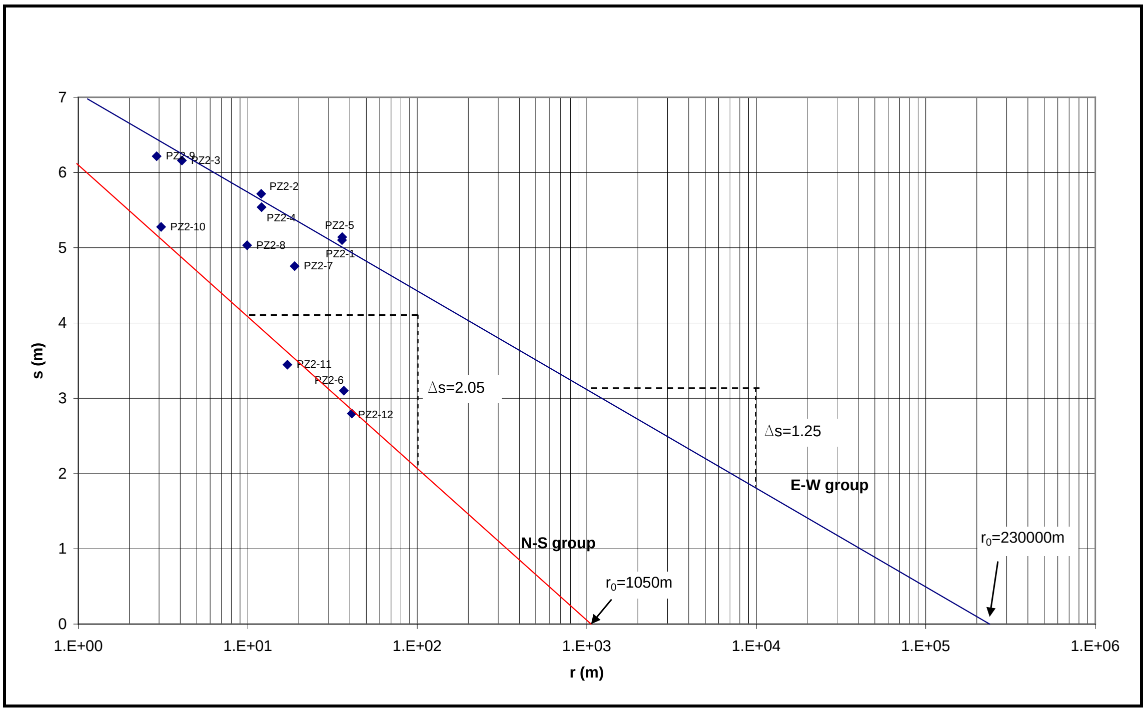

Figure 4-7 Distance-Drawdown plot 96 hours into test (t=345,600 sec).

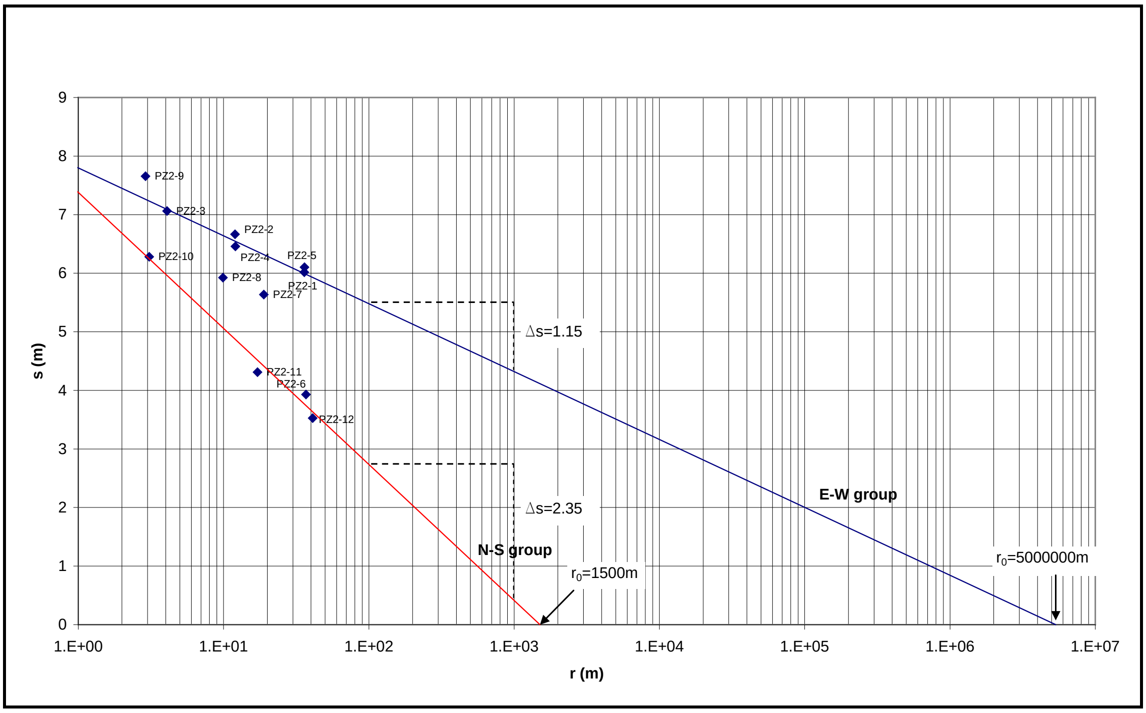

Results of the analysis are summarised in Table 4.3.

Table 4.3 Distance Drawdown Analysis Results

	N-S Group	
Time, seconds	**Transmissivity (m^2/s)**	**Storage coefficient**
43,200	2.9E-04	2.6E-04
86,400	2.4E-04	4.6E-04
172,800	2.7E-04	9.6E-05
345,600	2.4E-04	8.2E-05
	E-W Group	
Time, seconds	**Transmissivity (m^2/s)**	**Storage coefficient**
43,200	5.2E-04	6.0E-09
86,400	5.3E-04	1.1E-09
172,800	4.5E-04	3.3E-09
345,600	4.9E-04	1.5E-11

The N-S group has an average transmissivity of 2.6×10^{-4}, whilst the E-W group is 5.0×10^{-4}. This shows strong evidence of horizontal anisotropy in the formation with $T_{E\text{-}W}$:$T_{N\text{-}S}$ ratio of ~2:1 (actually 1.89:1).

The storage confidents derived by the distance drawdown method are extremely sensitive to the intercept of the fitted straight line. Therefore, little account is taken of storage estimates from this method.

5. Recovery test

Theis recovery analysis was conducted on 4 of the piezometers: PZ2-1, PZ2-4, PZ2-8 and PZ2-12 . These were chosen to as representative of the 4 lines of piezometers extending from the pumped well. The resulting plots are presented in Appendix B and, in the same way as the Cooper-Jacob analysis, two plots show a manual fit to the early time data, and an automated fit to the whole of the recovery information. Table 5.1 summarises the results of the analysis.

Table 5.1 Summary of Theis Recovery analysis

	Manual analysis (early time)	
Piezometer	**Transmissivity (m^2/s)**	**Storage coefficient ratio**
PZ2-1	2.1E-04	0.037
PZ2-4	2.5E-04	0.013
PZ2-8	2.5E-04	8.7E-03
PZ2-12	7.6E-04	7.6E-08
	Automated analysis	
Piezometer	**Transmissivity (m^2/s)**	**Storage coefficient ratio**
PZ2-1	8.4E-05	1.3
PZ2-4	8.7E-05	1.3
PZ2-8	8.6E-05	1.2
PZ2-12	1.0E-04	1.1

As before, the manual analysis of early time recovery is thought more accurate due to increasing influence of the postulated boundary at later times. The plots of recovery data from the piezometers show the aquifer to have nearly fully recovered by the end of monitoring on 6th August, with a residual drawdown of 0.07 to 0.11 m compared to maximum drawdowns of 3.5-6.5 m.

The Storage coefficient ratio is given by:

$$Storage\ ratio = \frac{S}{S'}$$

Where:

- S is the storage seen during the pumping phase; and,
- S' is the storage seen during recovery.

Taking the storage values from the pumping phase derived by Cooper-Jacob manual analysis, given in Table 4.2, the following estimates of the storage from the early part of the recovery analysis are:

- PZ2-1, $5x10^{-4}$;
- PZ2-4, $6x10^{-3}$; and,
- PZ2-8, 0.04.

These are much closer to specific yield values typically found for unconfined aquifers, 0.01-0.2. Note that the value of storage ratio for PZ2-12 yields a storage value greater than 1, which is nonsensical.

The recovery plots show some straight line behaviour at early recovery times, when the t/t' ratio is 100-1000. This corresponds to approximately the first hour of the recovery period. The rest of the recovery shows a curved response (in log time) with recovery becoming more rapid. This is interpreted as:

- The early time response corresponds to recovering levels replacing unconfined storage around the pumped well. Hence the rate of recovery is relatively slow.
- At later times (lower values of t/t'), after approximately 10 hours of recovery, levels have recovered such that the dewatered part of the aquifer has refilled, the aquifer is once again confined and recovery occurs more rapidly (on log time).

This switch during pumping and recovery phases, from confined, to unconfined and then back to confined behaviour, can not be represented fully by analytical analysis. More information, particularly concerning the unconfined storage (specific yield) could be obtained from numerical analysis of pumping and recovery phases.

6. Further interpretation

The response to pumping beyond around 40,000 seconds (~ 11 hours) shows increasing drawdown with log time. Under the Cooper-Jacob analysis this is interpreted as a boundary effect.

In the recovery analysis there is a strong suggestion that the test is providing an unconfined response, and that this is present to around 10 hours. It is also the case that the pumped well is substantially dewatered during the test, to within only 2-3m of the base of the well.

The dewatering and low water levels in the pumped well should not influence the response seen at observation piezometers, other than a switch to unconfined conditions. Therefore, the presence of a boundary is the most likely interpretation of the pumping response seen. This barrier acts to significantly reduce permeability. It is difficult to be precise in the distance and direction of the boundary, but calculations based on the Cooper-Jacob derived hydraulic properties indicate an approximate distance of 400-600 m (based on a transmissivity of 2.5×10^{-4} m^2/s and storage 5×10^{-4}). The direction of the boundary is not clear. The exact nature of the boundary is unknown, but it could be related to thinning of the formation to the south or indicate a fault.

APPENDIX 15E: BASELINE – DETAILED NON-RADIOLOGICAL GROUNDWATER CHEMISTRY

[This page is intentionally left blank]

APPENDIX 15E: BASELINE – DETAILED NON-RADIOLOGICAL GROUNDWATER CHEMISTRY

15E.1 Built Development Area West (BDAW)

15E.1.1 AMEC have undertaken a groundwater quality monitoring programme on the BDAW. The monitoring programme comprised a total of five monitoring campaigns, in December 2008; and in January, March, April and June 2009. Technical reports detailing a summary of the findings from these five monitoring campaigns are included in the AMEC report (Ref. 15E.1)

15E.1.2 During each campaign pumped groundwater samples have been collected (following purging in accordance with standard procedures) from eleven borehole piezometers installed as part of the on-shore investigation undertaken for EDF by Structural Soils Ltd. The boreholes included in the groundwater quality programme are indicated on **Figure 15.12** and **Figure 15.13** in **Chapter 15, Volume 1**. Three of the piezometers (CBH11 - response zone in Blue Lias; and CBH16 and CBH29 - response zone in Blue Anchor Formation) were screened to allow sample recovery from the deep groundwater at depths ranging from 35m to 48mbgl, with the remaining eight piezometers being screened to sample the shallow Blue Lias groundwater (CBH20, CBH21, CBH24, CBH25, CBH27, CBH33, CBH35, DBH09 - response zones ranging between 3.5mbgl to 18.5mbgl). Of the shallow piezometers, CBH35 represents Mercia Mudstone formation water.

15E.1.3 General baseline groundwater chemistry is shown in **Table 15E.1**, and potential contaminants in **Table 15E.2**.

15E.1.4 Determinands were analysed by the following methods:

- probe (Field measurement);
- salinity;
- probe (laboratory measurement);
- electrical conductivity, pH;
- ICPMS (Inductively Coupled Plasma/Mass Spectrometry);
- Arsenic (As), Boron (B), Cadmium (Cd), Chromium (Cr), Copper (Cu), Iron (Fe), Lead (Pb), Nickel (Ni), Mercury (Hg), Vanadium (V), Zinc (Zn), Sodium (Na), Calcium (Ca), Magnesium (Mg), Potassium (K);
- calculation;
- Total Hardness as $CaCO_3$;
- titration;
- Bicarbonate (HCO_3);
- Ion chromatography;

- Chloride (Cl), Nitrite (NO2), Nitrate (NO3), Ammonium (NH4), Sulphate (SO4), Phosphate (PO4);
- colorimetry;
- Total Cyanide (CN);
- gravimetry;
- Total Suspended Solids;
- five day and reflux;
- Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD);
- GCFID (Gas Chromatography/Flame Ionisation Detector);
- Total Petroleum Hydrocarbons (TPH);
- GCMS (Gas Chromatography/Mass Spectrometry); and
- polyaromatic hydrocarbons (PAHs) and other hydrocarbons.

15E.1.5 The suite of baseline groundwater quality determinands above were selected to include a wide range of determinands and quality indicators frequently tested for in preliminary UK groundwater quality assessments, as well as a wide range of potential contaminants that are commonly associated with current and historical contaminative activities. The suite includes basic indicators of potential pollution e.g. ammonia, electrical conductivity, chloride, and BOD. Inorganic parameters such as nitrate, nitrite and phosphate have been included particularly given the current and historical agricultural use (i.e. to see if any impact to groundwater from the application of fertilisers may have occurred) and given that the area is within a Nitrate Vulnerable Zone. Electrical conductivity, chloride and sodium have also been included as these are key parameters which can help to evaluate the origins of more saline groundwaters. Other major anions and cations (e.g. sodium, chloride, calcium, magnesium, potassium, and sulphate) have been included as indicators of general groundwater quality but are also useful in helping to assess potential geological/geochemical impacts to groundwater (e.g. mineralisation/salinisation caused by mineral deposits in the bedrock).

15E.1.6 Ongoing results of groundwater quality monitoring campaigns have been presented regularly at meetings with stakeholders including the Environment Agency. These have allowed for discussion and raising of any areas of concern over the results and the interpretation put on them. In particular, soil and water quality data were presented to the Marine Authorities Liaison Group (MALG) meeting of 28 July 2009.

a) Tier 1 Groundwater Assessment Methodology - BDAW

15E.1.7 A Tier 1 groundwater risk assessment using the analytical results has been undertaken. Initial assessment involved the comparison of the groundwater concentration with relevant UK Drinking Water Standards (DWS) and the Marine and Freshwater Environmental Quality Standards (EQS). This is a standard practice in the UK whereby concentrations of determinands within the site groundwater are initially compared (conservatively) to accepted UK Drinking Water Standards. This is routinely carried out in Tier 1 groundwater quality assessments in the UK whether or not the groundwater in the area is – or has the potential to be

- used for drinking water purposes. In addition, the groundwaters have also been compared to marine and freshwater EQS values, as the hydrogeological conceptual model has indicated that groundwaters are likely to discharge to marine and/or fresh water on/off site.

15E.1.8 In December 2009, Directions were issued by the UK government to the Environment Agency which allowed revised water environmental quality standards developed by UKTAG (United Kingdom Technical Advisory Group) for the Water Framework Directive (WFD) to be implemented. The WFD EQS values adopted for Hinkley (and validated by EDF) are presented in **Table 15E.1** alongside previous standards (and in **Table 15E.4** for the BDAE and **Table 15E.6** for the SCPA).

b) Derivation of the Revised Screening Values

15E.1.9 To assess the risks to groundwater and surface waters at Hinkley in line with the requirements of the WFD, AMEC adopted the published Tier 1 screening values published by the UK Technical Advisory Group on the Water Framework Directive.

15E.1.10 AMEC have also conducted a review of the River Basin Management Plan for the South West to determine if any specific threshold values were published for the controlled water receptors identified in the Conceptual Site Model (i.e. groundwater in the Secondary A aquifer and the Hinkley Point C drainage ditch and Holford Stream surface water systems).

15E.1.11 The review of the water body status objectives set for the South West district indicated the following:

- The water body status objectives for the Secondary Aquifer in proximity to the study area confirmed that it is not located in a designated Groundwater Water Protection Area established under the Water Framework Directive. No threshold values for Groundwater Impacts on Surface Waters (Test 2 in Part 7 of the groundwater threshold values) have therefore been set for the underlying Secondary A aquifer underlying and in proximity to the study area.
- The on-site surface water receptors (Hinkley C drainage ditch and Holford Stream) have no water body status objectives set under the WFD and the River Basin Management Plan (Annex B) for the South West. However, as Holford Stream is a tributary of the Stogursey Brook (albeit the confluence located at a downstream location), which has water body status objectives itself, the EQS values (for water chemistry) for Stogursey Brook have been adopted and the EQS values for ‘good’ quality water have been applied.
- Water body status objectives for Stogursey Brook have been specified in the water body status objectives. The Stogursey Brook water body status is currently classified as an overall ‘Poor’ WFD standard with the objective of reaching ‘Good Ecological Status’ by 2015 for a select number of water chemistry parameters;
- Where applicable these have been used, together with the target status of ‘Good’ to define appropriate EQSs under the WFD for the assessment of risk from groundwaters to surface water receptors. In each case, the highest available status score has been chosen, given that the WFD dictates no deterioration of any component water quality parameter should occur.

15E.1.12 The WFD provides a range of EQS values which have to be adjusted to account for site specific conditions (e.g. hardness and alkalinity). The following provides discussion of where AMEC have specified site specific EQS values:

- The WFD EQSs for Total Ammonia and Biochemical Oxygen Demand (BOD) (Part 3 Physico-chemical Standards) have been based on the criteria for Type 7 surface water systems. The surface water receptors have been classified as Type 7 surface waters based on the calculated average alkalinity of the Hinkley C drainage ditch and Holford Stream watercourses being greater than 200mg/l (as CaCO3) and the study area altitude being less than 200mAOD in accordance with Part 2 Table 1 of the River Basin Districts Typology, Standards and Groundwater threshold values.
- The Freshwater EQS for copper has been based on freshwater controlled water receptors containing an annual mean carbonate (alkalinity) greater than 200mg/l CaCO3.
- The EQS for cadmium has been based on the receiving controlled waters being classed as class 5 based on the hardness value being greater than 200mg/l as CaCO3.
- The EQS for total zinc has been based on the corresponding value for controlled water receptors containing an annual mean hardness concentration of greater than 250mg/l CaCO3.

15E.1.13 As the study area lies outside a groundwater water protected area, there are no water body status objectives (for groundwater impacts on surface waters in accordance with part 7 of the WFD) specified for the aquifer underlying the study area. Therefore, in the absence of these values, the EQS values are based solely on the EQS values of ‘good’ standard for freshwater rivers (part 4 specific pollutants) and EQS values for priority substances for inland waters (Part 5 priority substances) in accordance with Test 2 detailed in the Groundwater Classification System and its Application in Regulation document.

15E.1.14 Based on the review of the water body status objectives specified in the River Basin Management Plan and the status of the controlled water receptors identified, all EQS values have been revised in line with the WFD where applicable (**Table 15E.2, Table 15E.4** and **Table 15E.6**), with the exception of the values specified for Groundwater Drinking Water in Test 4 and Test 5. The current UK Drinking Water Supply Regulations (2000) are retained as screening values to assess the risks to groundwater, and using the test 4 screening value where no current drinking water screening values are available.

15E.1.15 The main EQS values (for groundwater drinking water) are not adopted in total due to the study area not being located within a Groundwater Water Protected Area, for which these values apply; and that they are set at a percentile of the UK Drinking Water Supply Regulation Values which is not considered to be applicable to the environmental setting of the study area.

15E.1.16 All of the saltwater surface water EQS values specified in the Directions to assess the risks from potentially contaminated groundwater to saltwater receptors (Bridgwater Bay which has a water body status objective set for 2027 under the WFD) are adopted. These screening values are also appropriate as the Hinkley C drainage ditch (which is potentially in continuity with the groundwater in the study area) discharges directly into Bridgwater Bay.

15E.1.17 All of the freshwater / surface water EQS values specified in the River Basin Districts Typology, Standards and Groundwater Threshold Values to assess the potential risk posed to on-site surface water receptors from potentially contaminated groundwater are adopted. These EQS values have been based on the water body status objective for Stogursey Brook being 'good' status by 2015.

15E.1.18 For determinands where no EQS value (saltwater or freshwater) are set out in the Directions, AMEC has used the previous EQS values specified as screening criteria.

c) Groundwater Quality - BDAW

15E.1.19 **Table 15E.1** below presents a summary of the major ion chemistry on the BDAW.

Table 15E.1: Summary of Groundwater Major Ion Chemistry on Built Development Area West

Parameter	Range Detected in Shallow Groundwater	Range Detected in Deep Groundwater
Total Hardness (mg/l as $CaCO_3$)	320-511	1,836-11,211
pH Value (Units)	6.2-8.3	6.3-9.7
Electrical Conductivity (µS/cm)	793-2,410	4,050-162,700
Calcium (mg/l)	70.0-143.7	200.3-7,367
Magnesium (mg/l)	17.8-62.9	31.6-881.3
Sodium (mg/l)	22.5-151.2	112.0-56,239
Potassium (mg/l)	2.4-8.7	30.1-336.9
Ammonium (converted to NH_4-N) (mg/l)	<0.01-0.89	0.79-30.35
Chloride (mg/l)	13-141	571-72,315
Sulphate (mg/l)	16-156	<5-9,002
Bicarbonate (mg/l as $CaCO_3$)	194-353	20-591
Nitrate (mg/l)	<1-103	<1-290

15E.1.20 Shallow Groundwater is generally intended to mean groundwater present in the Secondary A Aquifer in the underlying Blue Lias Formation and Penarth Group strata which is usually < 20mbgl, although piezometers DBH2_7 and CBH2_55 have been installed as combined monitoring installations to target the deeper Blue Lias Formation.

15E.1.21 Deeper Groundwater is intended to mean groundwater present in the underlying Blue Anchor Formation of the Mercia Mudstone Group, which is generally >40mbgl.

15E.1.22 The pH of the groundwaters within the BDAW was found to be quite consistent throughout the monitoring campaign across the shallow piezometers. More variation was identified across the deep piezometers with one location (CBH16) showing lower pH levels (ranging from pH 6.3 to 6.5) and one location showing significantly higher pH levels (CBH29 ranging from pH 7.0 to 9.7). Groundwater in CBH16 has very high (non-sea water) salinity (see below) whilst CBH29 groundwater is very low in bicarbonate alkalinity and therefore has limited buffering capacity against pH changes.

15E.1.23 Relatively fresh groundwaters such as at CBH25 show values between 872 and 964µS/cm; the saline waters in CBH11 show values between 40,900 and 57,200µS/cm; and at CBH16 in the Blue Anchor formation with the very saline groundwater, values of over 150,000µS/cm are shown.

15E.1.24 In terms of general groundwater quality in the shallow Blue Lias groundwaters, CBH20 and CBH24 are the only ones that show signs of elevated concentrations of determinands related to sea water such as EC, chloride and sodium. Otherwise they represent typical hard calcium-bicarbonate type groundwaters.

15E.1.25 Highly saline groundwaters are found in the deep piezometers CBH11 and CBH16. CBH11 is nearest to the shoreline and at a similar distance to CBH24 and has chloride concentrations around 16,000mg/l and sodium around 12,000mg/l; at CBH16 chloride concentrations have reached around 70,000mg/l and sodium around 56,000mg/l (though not consistently).

15E.1.26 For context, an analysis of typical sea water is as follows (The Geochemistry of Natural Waters, 1997) (Ref. 15E.2). These concentrations are in mg/kg (to obtain values in mg/l it is necessary to multiply the values below by about 1.02-1.03).

- Na: 10,760 mg/kg;
- Cl: 19,350 mg/kg;
- Mg: 1,290 mg/kg;
- SO4: 2,710 mg/kg;
- K: 399 mg/kg;
- HCO3: 142 mg/kg; and
- Ca: 400 mg/kg (from http://www.lenntech.com/periodic/water/calcium/calcium-and-water.htm).

15E.1.27 Average values from sampling of estuary water at Hinkley (not done for all major ions) are 14,250mg/l for chloride, 8,500mg/l for sodium and 1,920mg/l for sulphate32. This is around 70-80% of the above typical sea water values (after conversion to mg/l) and reflects the estuarine rather than fully marine condition at Hinkley.

15E.1.28 At CBH11 chloride concentration is similar to a slightly diluted typical sea water, but sodium is higher and sulphate is very low. At CBH16 sulphate and potassium concentrations are similar to typical sea water but the chloride and sodium concentrations are much higher and calcium concentrations are also very high (up to 7,367mg/l). This latter is indicative of a formation mineral or interstitial groundwater origin (halite and gypsum/anhydrite) rather than modern sea water.

d) Potential Groundwater Contaminants - BDAW

15E.1.29 The samples collected during the monitoring campaigns have been analysed for potential non-radiological and radiological contaminants. A summary of the non-radiological analytical results is provided in **Table 15E.2**. Full non-radiological analytical results are included in Ref. 15E.1.

Table 15E.2: Summary of Non-Radiological Groundwater Analytical Results for Built Development Area West

Source Table B11 Environment Agency EPR H1 Environmental Risk Assessment Part 2 Assessment of point source releases and cost benefit analysis. Source Table B11 Environment Agency EPR H1 Environmental Risk Assessment Part 2 Assessment of point source releases and cost benefit analysis.

The River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2010

The Water Supply (Water Quality) Regulations 1989. N.B These Regulations were superseded by the 2000 regulations therefore there is currently no UK DWS for zinc and / or Total Petroleum Hydrocarbons.

The Surface Waters (Abstraction) for Drinking Water (Classification) Regulations 1996. DW1 treatment (i.e. simple physical treatment and disinfection) limit.

The Surface Waters (Dangerous Substances) (Classification) Regulations 1989

2006 / 44/ EC Fish Directive - Cyprinid Fish Guideline.

The Private Water Supply regulations 1992 N.B. These regulations were superseded by 2009 regulations therefore there is no current UK DWS for these determinands.

^ Guideline Value - Non statutory / proposed EQS, but EQS never adopted in UK.

DPA - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Part 7 Groundwater Threshold Values for Groundwater Drinking Water Protected Areas.

- no current threshold value available

 # - Corrected based on the reported average hardness value (399m /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

C5 - Cadmium EQS based on class 5 hardness (>200mg/l $CaCO_3$), corrected based on the reported average hardness value (399mg /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

D - Dissolved

T - Total

A - Annual average

P - 95-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 5% of the time or more).

P90 - 90-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 10% of the time or more).

P5 - 5-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is less than the standard for 5% of the time or more).

MAC Maximum Allowable Concentration

T7 - Type 7 surface water.

G15 - Threshold value based on 'good standard' to meet objective of WFD for Stogursey Brook to achieve good status by 2015.

GC - Threshold value based on 'good standard' for transitional and coastal waters to meet objective of WFD for Bridgewater Bay to achieve good ecological status by 2027 (no chemical criteria target thresholds specified).

FCN - Threshold value for free cyanide (as HCN)

H - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Threshold value for high standard.

$ No assessment criteria is currently available for dissolved boron and therefore the dissolved boron concentrations have been compared to total values.

** LOD   Exceedances of the annual average EQS have occurred due to the limit of detection (LOD) not being low enough. This is a consequence of applying new and lower EQS values to data obtained before the issue of these new, lower values. However, these ‘exceedances’ are not considered to be environmentally significant.*

DWS - Drinking Water Standard

F EQS – Freshwater Environmental Quality Standard (EQS)

i. Shallow Groundwater

15E.1.30 The groundwater results showed generally low concentrations of inorganic contaminants such as heavy metals and metalloids, below the relevant screening values (see **Table 15E.2**), across all shallow piezometers, with the exception of some isolated exceedences of specific contaminants, with subsequent monitoring having identified the return of concentrations to below the relevant screening values. Isolated elevated concentrations of dissolved and total boron and/or slightly elevated ammonium have been identified in one or two of the boreholes.

15E.1.31 Concentrations of nitrates in shallow groundwater are slightly above normal background and indicate a slight existing impact, most probably associated with application of nitrogenous fertilisers or ploughing of organic-rich soils, historical and/or current agricultural fertiliser application on and off site. However, nitrate concentrations in excess of the DWS (50mg/l) were only exceeded at one location (CBH35).

15E.1.32 Concentrations of organic contaminants, i.e. Polycyclic Aromatic Hydrocarbons (PAHs), Total Petroleum Hydrocarbons (TPHs) and Volatile Organic Carbons (VOCs) were below the limit of detection and below the relevant screening values across all shallow groundwater locations, with the exception of an elevated TPH concentration identified in one shallow piezometer (CBH27, 29µg/l) located on the western boundary of the BDAW during the first monitoring campaign. However, all subsequent campaigns have recorded concentrations below the limits of detection (<10µg/l).

15E.1.33 Concentrations of suspended solids regularly exceeded the screening criteria.

ii. Deep Groundwater

15E.1.34 Elevated concentrations of several heavy metals and metalloids have been identified in the deeper groundwaters in boreholes CBH16 and CBH11 which are located in the central eastern and northern areas of the BDAW, respectively. The concentrations of some of these (e.g. boron, copper, nickel, iron, mercury and zinc) have frequently exceeded Tier 1 groundwater and surface quality standards. Elevated concentrations of ammonium were also present within the deeper groundwaters.

15E.1.35 The source of these elevated contaminant concentrations is believed to be from the leaching of minerals and pockets of naturally occurring organic matter within the Blue Anchor Formation bedrock.

15E.1.36 Concentrations of organic contaminants, i.e. PAHs, TPHs and VOCs were all below the limit of detection and respective groundwater and surface water quality standards.

15E.1.37 Concentrations of suspended solids regularly exceeded the screening criteria.

e) Summary for BDAW

i. Shallow Groundwater

15E.1.38 The shallow groundwaters across the BDAW show very little evidence of any contamination by non radiological contaminants, with the exception of very isolated and occasional occurrences of certain heavy metals, ammonia and nitrate. However these are considered to be naturally elevated and not the result of anthropogenic (man-made) contamination. The concentrations of suspended solids regularly exceed the surface water environmental quality standard, although this is only of environmental significance if, during construction dewatering, water containing suspended solids is discharged to a surface water receptor. (Further assessment of the potential impacts from dewatered groundwater discharged to surface water receptors is contained in **Chapter 14** of this volume).

15E.1.39 Slightly elevated, and (in the case of CBH35) elevated nitrate concentrations are present in the shallow groundwater on the BDAW. In all cases (with the exception of CBH35) these are below the recognised environmental screening criterion of 50mg/l. The source of these slightly elevated and elevated nitrate concentrations is likely to be application of nitrogenous fertilisers or ploughing of organic-rich soils. The Hinkley Point area is a designated Nitrate Vulnerable Zone, which means that from an environmental impact assessment point of view, the groundwaters and surface waters in the area are sensitive to activities during the construction and operation of the proposed development that could give rise to nitrate pollution.

ii. Deep Groundwater

15E.1.40 The deep groundwaters have been found to contain elevated concentrations of several heavy metals, metalloids, ammonium and suspended solids. However these are considered to be naturally elevated and not the result of anthropogenic (man-made) contamination.

15E.1.41 Given the depth of the deeper groundwater (i.e. >30m bgl), the environmental significance of these elevated concentrations is very low as they are not generally in any direct contact with potential receptors. The fact that the deeper groundwater already has naturally elevated baseline concentrations of certain contaminants, means that they are less sensitive to activities during the construction and operation of the proposed development that may give rise to pollution or contamination. As a result of the elevated heavy metals and ammonia (and elevated salt and mineral content), these deeper groundwaters are unlikely to be used for possible potable or industrial waters (e.g. cooling). The resource potential of the deeper groundwaters is therefore considered to be very low.

15E.2 Built Development Area East (BDAE)

15E.2.1 The desk based assessment detailed in **Chapter 14** of this volume has identified a number of historical and current potentially contaminative activities (e.g. spoil deposition, waste management, construction and fabrication areas, former sewage treatment works, fuel storage tanks, and the adjacent Hinkley Point A power station complex) both on and off the BDAE.

15E.2.2 An extensive programme of groundwater quality monitoring (similar in size and scope to that conducted on the BDAW above) has been undertaken on the BDAE which has included the sampling of twenty one piezometers (nineteen monitoring 'shallow' groundwater and two monitoring 'deep' groundwater) across the BDAE to establish the baseline groundwater quality on the site. Groundwater samples have been collected from all twenty one piezometers on three occasions. Thirteen of the twenty one piezometers have been sampled on four occasions (eight of the piezometers were either not installed or developed at the time of the first partial monitoring round in June 2010, which is why some piezometers have three sets of data only). The groundwater samples have been screened for a wide variety of non radiological and radiological contaminants based on the historical land use. Locations of the BDAE groundwater monitoring piezometers are shown on **Figure 15.15**.

15E.2.3 Four of the piezometers (DBH2_10, DBH2_21, DBH2_22 and DBH2_27) have been installed along the eastern boundary of the BDAE to monitor for potential cross boundary groundwater contaminant migration from the adjacent HPA power station complex.

15E.2.4 As with the BDAW above, for monitoring and assessment purposes, the groundwater on the BDAE has been divided into 'shallow' and 'deep' groundwater. The 'shallow' groundwater includes the Secondary A Aquifer in the underlying Blue Lias Formation and Penarth Group strata. The majority of the response zones monitoring the 'shallow' groundwater are installed between depths of 1 – 15mbgl, however, DBH2_7 and CBH2_55 are installed slightly deeper in the Blue Lias at 25-33mbgl and 22-24mbgl, respectively. DBH2_7 and CBH2_55 have been installed as combined monitoring installations to target the deeper Blue Lias to see if there are any differences in groundwater chemistry with depth in the Blue Lias.

15E.2.5 The 'deep' groundwater includes the unproductive strata in the underlying Blue Anchor Formation of the Mercia Mudstone Group. The piezometers (CBH2_53 and CBH2_54) have been installed to target the 'deeper' groundwater in the Blue Anchor Formation. A detailed rationale for the groundwater monitoring strategy on the BDAE is provided in AMEC Report (Ref. 15E.3)

15E.2.6 The results of the non radiological data are summarised in **Table 15E.3** (Groundwater Major Ion Chemistry on the BDAE) and **Table 15E.4** (Summary of Non-Radiological Groundwater Analytical Results for the BDAE) and discussed below. For a more detailed assessment and discussion of the non radiological and radiological groundwater quality data, the reader is referred to the AMEC report. (Ref. 15E.4)

a) Tier 1 Groundwater Assessment Methodology - BDAE

15E.2.7 This is described under BDAW groundwater quality section above.

15E.2.8 **Table 15E.3** below presents a summary of the general and major ion chemistry on the BDAE.

Table 15E.3: Groundwater Major Ion Chemistry on the BDAE

Parameter	Range Detected in Shallow Groundwater	Range Detected in Deep Groundwater
Total Hardness (mg/l as $CaCO_3$)	178-1377	106-12,408
pH Value (Units)	6.8-12.9	6.9-12.5
Electrical Conductivity (µS/cm)	739-18,200	1,256-125,600
Calcium (mg/l)	36.4-404.5	36.2-3866.0
Magnesium (mg/l)	0.2-151.7	1.1-669.9
Sodium (mg/l)	29.9-3,985.0	120.8-42,990.0
Potassium (mg/l)	2.8-351.4	15.4-240.1
Ammonium (as NH_4) (mg/l)	<0.01-2.53	0.62-14.16
Chloride (mg/l)	33-5,156	9-64,253
Sulphate (mg/l)	4-803	29-3359
Bicarbonate (mg/l as $CaCO_3$)	<5-2800	<20-230
Nitrate (mg/l)	<1-30	<1-4

Shallow Groundwater is generally intended to mean groundwater present in the Secondary A Aquifer in the underlying Blue Lias Formation and Penarth Group strata which is usually < 20m bgl, although piezometers DBH2_7 and CBH2_55 have been installed as combined monitoring installations to target the deeper Blue Lias Formation.

Deeper Groundwater is intended to mean groundwater present in the underlying Blue Anchor Formation of the Mercia Mudstone Group, which is generally >40m bgl.

i. Shallow Groundwater

15E.2.9 The concentrations of sulphate in the shallow groundwater are generally low and below respective Tier 1 screening criteria. The exceptions are slightly elevated to elevated concentrations of sulphate which have been identified in all campaigns for DBH2_8 (289 – 347mg/l), DBH2_23 (549 – 803mg/l), NBH01 (453 – 550mg/l) and NBH04 (444 – 679mg/l Campaigns 1, 3 and 4). All of these piezometers are situated in the north western area of the BDAE down gradient of the existing mound and in the area of the former NDA spoil disposal area.

15E.2.10 The shallow piezometers recorded concentrations of calcium and potassium generally below the Tier 1 screening criteria over the four campaigns. Exceptions to this were noted for potassium in piezometers DBH2_7, DBH2_8, DBH2_9, DBH2_27 and CBH2_55, and for calcium in DBH2_9, DBH2_20, DBH2_23 and DBH2_26. Again, many of these piezometers are in the northern area of the BDAE, either downgradient of the existing mound or in the former NDA spoil disposal area. The highest concentrations of calcium and potassium were noted in DBH2_9 which is situated in the south western corner of the existing spoil mound.

15E.2.11 Elevated concentrations of magnesium have been recorded on at least one occasion in twelve of the nineteen ‘shallow’ piezometers. Most of these piezometers are located in the northern part of the BDAE. The highest concentrations of magnesium were noted in piezometers NBH01, NBH04, and DBH2_23, which are located in the northern area of the BDAE, downgradient of the existing mound and / or in the former NDA spoil disposal area. Of note, is the very low magnesium concentrations and elevated pH in DBH2_9 (this being despite the fact that DBH2_9 had the highest relative concentrations of calcium and potassium). Concentrations of magnesium in the deep groundwater in CBH2_54 and CBH2_53 at 41mbgl (see below) are much lower than the shallow groundwater. This could indicate that the source of the groundwater contamination in DBH2_9 could be from reworked deep historical excavation material placed within this area of the mound.

15E.2.12 The concentrations of sodium and chloride in the shallow groundwater on the BDAE are generally low and below the Tier 1 screening criteria. However, exceedances of the Tier 1 screening criteria for sodium and/or chloride were recorded in DBH2_7, DBH2_9, DBH2_24, DBH2_27, CBH2_30 and CBH2_55. Five of these piezometers are located in the northern part of the BDAE and one (DBH2_9) is located in the south western mound area.

15E.2.13 Sodium and chloride concentrations in the shallow piezometers varied with depth in the Blue Lias groundwater. The highest concentrations of sodium and chloride were recorded in DBH2_7 and CBH2_55 which target the deeper groundwater in the Blue Lias.

15E.2.14 The three piezometers located adjacent to the coastline (DBH2_24, DBH2_26, and CBH2_57) did not record elevated concentrations of sodium and/or chloride, or only marginal exceedances, indicating no or very limited saline intrusion.

ii. Deep Groundwater

15E.2.15 Very high concentrations of sulphate, exceeding the Tier 1 screening values have only been consistently recorded in CBH2_53. Slightly elevated sulphate concentration (712mg/l) was also recorded at CBH2_54 in the second campaign.

15E.2.16 The concentrations of the major ions (calcium, magnesium and potassium) recorded in the deep groundwater varied significantly between the two deep piezometers. The highest concentrations of these determinands were consistently recorded above the Tier 1 screening values at CBH2_53 in the three campaigns (in samples taken from 48m and 53mbgl). In contrast, the range in values for the major ions at CBH2_54 was much lower although the Tier 1 screening criteria for potassium was exceeded in the three campaigns.

15E.2.17 Very high concentrations of sodium (37,000 – 42,990mg/l) and chloride (40,812 – 64,253mg/l) were present in the deep piezometer CBH2_53 which were significantly higher than the shallow piezometers. Elevated, but much lower concentrations of sodium and chloride were noted in CBH2_54. The concentrations of sodium and chloride recorded were recorded in exceedence of the Tier 1 Screening Criteria (DWS and Freshwater EQS) at CBH2_53 for all three campaigns but only at CBH2_54 on the second campaign and fourth campaign.

15E.2.18 The very high concentrations of sodium and chloride (well in excess of typical sea water concentrations – see above), as well as the Cl:SO4 ratio being around 20 (as opposed to around 7 in seawater) suggest that the source of the hypersalinity at the base of CBH2_53 is a formation mineral source. Halite (NaCl), gypsum and anhydrite were visually identified within the Blue Anchor Formation on the Structural Soils Limited borehole log for CBH2_53, suggesting that the source of the hyper salinisation and mineralisation in CBH2_53 is a principal formation mineral source. These findings are similar to those for the BDAW.

b) Summary for BDAE

15E.2.19 The general and major ion analysis and interpretation demonstrates that there are clear differences between the shallow (generally the Blue Lias groundwater) and the deeper (Blue Anchor Formation) groundwaters on the Built Development Area East which is similar to that found on the Built Development Area West. Slightly elevated concentrations of several major ions were noted in several of the piezometers downgradient of current and historical potential sources such as the existing spoil mound and the former NDA temporary spoil storage area and general Made Ground in the former fabrication area. Groundwater in the deeper the Blue Lias (as represented by piezometers DBH2_7 and CBH2_55) shows higher concentrations of sodium and chloride relative to the shallower Blue Lias groundwater and demonstrates increasing salinity with depth.

15E.2.20 The deeper groundwaters (generally in the Blue Anchor formation) are noted to contain very high concentrations of salts and minerals. These are considered in the most part to result from naturally present minerals in the bedrock formation with which the groundwaters are in contact.

15E.2.21 The samples collected during the monitoring campaigns have been analysed for potential non-radiological and radiological contaminants. A summary of the non-radiological analytical results is provided in **Table 15E.4**. Full non-radiological analytical results are included in the Summary of Groundwater Quality Report (Ref. 15E.5).

Table 15E.4: Summary of Non-Radiological Groundwater Analytical Results for the BDAE

Determinand	Units	DWS	WFD Screening Values		Range of Concentrations in Deep Piezometers	Range of Concentrations in Shallow Piezometers

The Water Supply (Water Quality) Regulations 1989. N.B These Regulations were superseded by the 2000 regulations therefore there is currently no UK DWS for zinc and / or Total Petroleum Hydrocarbons.

The Surface Waters (Abstraction) for Drinking Water (Classification) Regulations 1996. DW1 treatment (i.e. simple physical treatment and disinfection) limit.

The Surface Waters (Dangerous Substances) (Classification) Regulations 1989

2006 / 44/ EC Fish Directive - Cyprinid Fish Guideline.

The Private Water Supply regulations 1992 N.B. These regulations were superseded by 2009 regulations therefore there is no current UK DWS for these determinands.

^ Guideline Value - Non statutory / proposed EQS, but EQS never adopted in UK.

DPA - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Part 7 Groundwater Threshold Values for Groundwater Drinking Water Protected Areas.

- no current threshold value available

 # - Corrected based on the reported average hardness value (399m /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

C5 - Cadmium EQS based on class 5 hardness (>200mg/l $CaCO_3$), corrected based on the reported average hardness value (399mg /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

D - Dissolved

T - Total

A - Annual average

P - 95-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 5% of the time or more).

P90 - 90-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 10% of the time or more).

P5 - 5-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is less than the standard for 5% of the time or more).

MAC Maximum Allowable Concentration

T7 - Type 7 surface water.

G15 - Threshold value based on 'good standard' to meet objective of WFD for Stogursey Brook to achieve good status by 2015.

GC - Threshold value based on 'good standard' for transitional and coastal waters to meet objective of WFD for Bridgewater Bay to achieve good ecological status by 2027 (no chemical criteria target thresholds specified).

FCN - Threshold value for free cyanide (as HCN)

H - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Threshold value for high standard.

$ No assessment criteria is currently available for dissolved boron and therefore the dissolved boron concentrations have been compared to total values.

** LOD Exceedances of the annual average EQS have occurred due to the limit of detection (LOD) not being low enough. This is a consequence of applying new and lower EQS values to data obtained before the issue of these new, lower values. However, these 'exceedances' are not considered to be environmentally significant.*

DWS - Drinking Water Standard

F EQS – Freshwater Environmental Quality Standard (EQS)

n/s = not sampled as piezometers not installed, developed and / or stabilised at the time of sampling

c) Tier 1 Groundwater Risk Assessment - BDAE

i. Shallow Groundwater

15E.2.22 The following provides a summary of the analytical data based on information presented in **Table 15E.4** and describes the main parameters of interest observed in the groundwater sampled from the 'shallow' groundwater piezometers on the BDAE.

ii. Metals and Metalloids

15E.2.23 Concentrations of metals and metalloids are generally very low and in most cases are below the Tier 1 screening criteria. Occasional, slight exceedances of some total and/or dissolved metals (e.g. arsenic, chromium, lead, copper, mercury and zinc) have been noted. Exceedances of total metals are probably also related to the high concentrations of suspended solids frequently noted in the groundwater samples and are a reflection of the difficultly of obtaining groundwater samples from piezometers with low suspended solids contents in certain geological formations even where the piezometers have been fully developed and professionally and properly installed and constructed (as is the case at Hinkley). The true quality of the groundwater is expected to be much better than indicated by some of the total metal results i.e. is likely to be more representative of the dissolved metal concentration results. The concentrations of elevated contaminants where they occur are typically only 1 – 3 times the conservative Tier 1 screening criteria concentrations and as such are not considered to be significant or of concern. In addition, elevated concentrations of total and / or dissolved boron and total iron in excess of the Tier 1 screening criteria have been noted more consistently in a number of the piezometers (e.g. DBH2_7, DBH2_8, DBH2_27, CBH2_30, CBH2_55, NBH01 and NBH03) mainly located in the northern part of the BDAE. Again, where the exceedances occur, they are generally only 1 – 3 times the conservative screening criteria and, as such, are not considered to be significant or of concern.

iii. Ammonia, Ammonium, Nitrite, Nitrate

15E.2.24 Most concentrations of ammonium and total ammonia recorded in the shallow piezometers were low and below the Tier 1 screening values. A number of exceedances of the DWS for ammonium were recorded in piezometers DBH2_7, DBH2_8, DBH2_9, DBH2_22, DBH2_24, DBH2_27, CBH2_30, CBH2_55, NBH01 and NBH03, most of which are located in the northern area of the BDAE, down gradient of the existing spoil mound or in the former NDA spoil disposal area. In some cases, the exceedances have been isolated, however, consistently slightly elevated ammonium concentrations have been noted in DBH2_9, DBH2_22, DBH2_27 and NBH03. The highest relative concentrations have been noted in DBH2_9 and DBH2_27, which are located within and downgradient of the mound area, respectively. However, concentrations, where slightly elevated are generally only 1 - 3 times the conservative Tier 1 screening criteria concentrations and are therefore not considered to be significant or of concern. The one exception to this, is DBH2_9 where, due to the very high pH, the proportion of the more aquatically toxic unionised ammonia (estimated by calculation) is higher and is calculated to be present in concentrations of up to 85 times the salt water EQS of 0.021mg/l.

15E.2.25 Concentrations of nitrate (as NO3) and nitrite (as NO2) in shallow groundwater have been consistently low in the range <1 – 30mg/l and <0.02-0.22mg/l respectively and below the DWS value of 50mg/l. Occasionally, slightly elevated (10 – 30mg/l) concentrations of nitrate have been detected, but as these are below the Tier 1 screening criteria these are not of concern.

iv. pH Value

15E.2.26 The pH values recorded in the shallow groundwater are typically neutral to slightly alkaline in the range of pH 6.8 (DBH2_20) to pH 8.4 (DBH2_7). However, elevated alkaline pH values in the range 12.0 to 12.9 have been consistently recorded in DBH2_9 which exceeded the DWS, freshwater and saltwater EQS values. The high laboratory pH measurements for DBH2_9 have been corroborated by in-situ field readings. DBH2_9 is located in the south western corner of the existing mound feature. One possible explanation for this unusually high pH could be the presence of alkaline anthropogenic materials (e.g. concrete, plaster, mortar etc) in the Made Ground in the mound. A further possible explanation for the high pH in DBH2_9 could be due to leaching from deep rock spoil materials (similar in geochemistry to the Blue Anchor formation noted at depth within CBH2_54*) that may have been historically deposited in the spoil mound in the locality of DBH2_9. (*Groundwater in the deep borehole CBH2_54 also has very high pH, but this is believed to be due to reactions with minerals in the bedrock and natural deeper groundwater geochemistry and not in any way related to the elevated pH in DBH2_9).

v. Electrical Conductivity Values

15E.2.27 Electrical conductivity values in the shallow piezometers generally range from 700 - 2,000µS/cm and have remained reasonably consistent for each of the four groundwater monitoring campaigns. Elevated conductivity values (i.e. above 2500µS/cm) have been recorded in DBH2_7, DBH2_9, DBH2_27, CBH2_30 and CBH2_55. All of these piezometers are in the northern area of the BDAE, down-gradient of the mound and / or in the former NDA spoil disposal area. The highest electrical conductivity values were noted in DBH2_7 and CBH2_55 (deeper Blue Lias groundwater) where the conductivities range from 5600 to 18,200µS/cm and 3,870 to 14,270µS/cm respectively and in DBH2_9 (2,340 to 9,780µS/cm). The elevated laboratory conductivities have been corroborated by in-situ measurements / depth profiling, which demonstrates a definite increase in electrical conductivity with depth in the Blue Lias aquifer. The slightly elevated electrical conductivity in DBH2_9 is likely to be related to leaching of salts and minerals form the anthropogenic Made Ground and / or natural reworked materials within this area of the mound.

vi. BOD and COD

15E.2.28 Slightly elevated concentrations of BOD (5 - 14mg/l), above the freshwater EQS value, have been recorded in most of the shallow piezometers on at least one occasion, although most BOD concentrations recorded in Campaigns 3 and 4 were generally below the limit of detection. Most of the exceedances are marginally above the Freshwater EQS, although a higher BOD values of 12 and 14mg/l was recorded in DBH2_9 and CBH2_56 in the third campaign. The elevated concentrations of BOD are generally only 1 - 3 times the conservative Tier 1 screening value and therefore are not considered to be significant or of concern.

vii. Suspended Solids

15E.2.29 The concentrations of suspended solids in the shallow groundwater ranged from <5 – 1,744mg/l and regularly exceed the Tier 1 screening criteria (25mg/l) in the all of the piezometers on the BDAE (with the exception of DBH2_8). The concentrations of suspended solids varied significantly across the BDAE and during different sampling rounds for the same piezometer.

viii. Organic Determinands (TPH, VOC, PAHs and PCB Congeners)

15E.2.30 The data from the groundwater monitoring campaigns indicates that there is no evidence of significant organic contamination (with respect to petroleum hydrocarbons, PCBs, PAHs and VOCs) in the shallow groundwater on the BDAE. Slightly elevated concentrations of benzene (6µg/l) and trichloroethylene (12µg/l) were recorded in DBH2_7 and NBH04 during the second campaign, but analyses during the first, third and fourth visits found the concentrations were <1µg/l. This would indicate that the initial positive result was a one off occurrence. The concentrations are not considered to be significant or of concern.

ix. CBH2_56 and CBH2_57

15E.2.31 During site investigations, a localised area of hydrocarbon impacted soil, associated with an historical fuel storage tank, was discovered around a trial pit (TE418) in the north eastern area of the BDAE. A number of additional trial pits were excavated around the area to delineate the vertical and lateral extent of the soil contamination. The trial pits indicated that the hydrocarbons were primarily associated with a thin layer of made ground at approximately 0.6-0.8mbgl, covering an area of approximately 100m^2. In addition, groundwater monitoring well CBH2_56 was installed immediately downgradient of the impacted area to determine see if there was any evidence of deeper vertical migration, or groundwater contamination. As an additional measure, piezometer CBH2_57 was installed a greater distance downgradient (approximately 40m to the north east) to determine if hydrocarbons were present in groundwater downgradient of the impacted soils.

15E.2.32 During the drilling of CBH2_56, a slight hydrocarbon odour was noted between 0.75mbgl and 0.80mbgl, increasing to a strong diesel hydrocarbon odour and observations of globules of viscous dark brown free product between 0.80mbgl and 1.50mbgl. Rotary coring flush from 1.6mbgl to 2.8mbgl was noted to have an associated layer of free phase product with a strong hydrocarbon odour. A slight to strong hydrocarbon odour and sheen on arisings was noted to 4.5mbgl (within the weathered Lias deposits), with staining between 2.8 - 3.0mbgl. No evidence of flush water contamination was reported during drilling arising from greater than 4.5mbgl and no contamination was evident within the core below that depth.

15E.2.33 During the drilling of CBH2_57, a slight hydrocarbon sheen was witnessed on flush water at 6.0mbgl, with an associated slight hydrocarbon odour from clay arisings when broken open; these appeared to have different visual and olfactory characteristics to the hydrocarbons observed within the shallow Made Ground within TE418 and within the Made Ground and shallow weathered Lias in CBH2_56. A faint hydrocarbon odour was also noted by the driller between 6.25 and 6.36mbgl. Clayey mudstone and clay partings arising from between 12.36 and 12.5mbgl, and at 15.0mbgl and 18.0mbgl were noted to have a very faint hydrocarbon odour. No other evidence of hydrocarbon contamination was witnessed in CBH2_57.

15E.2.34 Soil samples from CBH2_56 and CBH2_57 were submitted for detailed forensic hydrocarbon analysis at Jones Environmental Laboratories. The analysis indicated that the low levels of hydrocarbon detected in CBH2_56 were derived from biodegraded heavy fuel oil (i.e. an historic anthropogenic source) that was very similar to the source in TE418. The EPH fingerprint analysis for samples from CBH2_57 also indicated the hydrocarbon was from an historic anthropogenic source (a gas oil type middle distillates in the carbon range nC8-C28) but was of a different source and fingerprint to that in TE418 and CBH2_56.

15E.2.35 During subsequent groundwater monitoring, visual evidence of slight hydrocarbon contamination was observed in one piezometer (CBH2_56) which was described as a ‘rainbow’ sheen. However, analyses of the groundwater samples have not detected any elevated dissolved phase hydrocarbon contaminations in either CBH2_56 or CBH2_57. Therefore, it is concluded that the hydrocarbon impact noted in the soils the vicinity of TE418 has not resulted in significant groundwater contamination.

d) Tier 1 Screening Values - BDAE

i. Shallow Groundwater

15E.2.36 The greatest number of exceedances of the inorganic and metal and metalloid Tier 1 screening values for the shallow groundwater has occurred in the piezometers located in the northern part of the BDAE which are either down gradient of the existing spoil mound or in the former NDA spoil disposal area. These include piezometers, DBH2_7, DBH2_8, DBH2_9, DBH2_23, DBH2_27, CBH2_30, CBH2_55, NBH01 and NBH03. This would indicate that some slight inorganic and metal and metalloid contamination (principally total and dissolved boron and iron) has occurred in the northern BDAE down gradient of the existing mound and in the area of the former NDA spoil area.

15E.2.37 The presence of slightly elevated concentrations of inorganic determinands (e.g. sulphate, chloride, sodium, potassium, calcium, magnesium, pH and ammonium etc) is often associated with the storage and disposal of inert spoil materials such as construction and demolition wastes and excavated natural rock and subsoils and general made and disturbed ground. These types of materials present in the existing mound, the former NDA spoil area and the Made Ground present over much of the north eastern area of the BDAE.

15E.2.38 In order to help highlight the slight increase in certain major ions (e.g. Na, Cl, SO4, K, Ca, Mg and NH4) and metal and metalloid concentrations (e.g. B, Fe) that have been noted in some piezometers in the northern area of the BDAE which are down gradient of likely source features (e.g. the existing spoil mound, former NDA spoil disposal area and Made Ground in the former fabrication area) The Table in **Appendix 15D** presents a summary of the data ranges, means and number of exceedances of Tier 1 screening criteria for these piezometers against data for piezometers on the BDAE which are hydraulic gradient of these features (i.e. background relative to these sources) and also, for comparison, data from piezometers on the adjacent BDAW land which has no such sources (i.e. is considered to be representative of greenfield/natural background concentrations for the Hinkley Point Area).

15E.2.39 Comparison of the data ranges, means and number of Tier 1 exceedances for the piezometers down gradient of the these likely source features against the upgradient piezometers on the BDAE and natural background piezometers on the BDAW, generally shows higher concentrations and greater number of exceedances for most of these major ions and metals/metalloids, demonstrating that a slight impact has occurred from these determinands to the shallow groundwater in some areas of the BDAE which are down gradient of these likely source features.

15E.2.40 It should be stressed that the slightly elevated concentrations are not considered to be significant or of concern, particularly when the low the very low sensitivity and value of the groundwater in the Blue Lias on site is taken into account. Also, given that groundwater flow is towards the north-north-east (i.e. towards the Bristol Channel) it will ultimately discharge into the Bristol Channel, which will already have naturally high concentrations of most of these inorganic determinants as well as enormous dilution potential (see AMEC report34). There are no other surface water receptors downgradient of the BDAE meaning that the Bristol Channel is the only potential surface water receptor.

15E.2.41 The response zone of the monitoring installations in DBH2_7 and CBH2_55 were positioned within the deeper interbedded limestone and mudstones of the Blue Lias Formation. The conductivity values and concentrations of sodium and chloride recorded in these piezometers were much higher than those typically recorded in the shallower Blue Lias groundwater. Concentrations of total arsenic, total and dissolved boron, total and dissolved iron also tended to be more elevated in these slightly deeper piezometers. This finding is consistent with that found on the BDAW.

ii. Deep Groundwater

iii. Metals and Metalloids

15E.2.42 Elevated concentrations of several metals and metalloids (e.g. total and dissolved nickel, total and dissolved boron and total iron) in excess of the Tier 1 screening criteria have been consistently detected in CBH2_53. In addition, elevated concentrations of dissolved cadmium, chromium, copper, mercury and zinc have been occasionally noted in CBH2_53 and isolated elevated concentrations of total arsenic and total lead during second campaign. Elevated total and dissolved boron on the first campaign and dissolved iron on the second campaign were detected in CBH2_54. A comparison of the concentrations of metals and metalloids recorded shows that they vary in the two deep piezometers. A majority of the highest concentrations of metals were recorded in CBH2_53 which is the shallower of the deep boreholes.

15E.2.43 Again, where the exceedances have occurred, they are generally only 1 - 3 times the conservative Tier 1 screening criteria, therefore are not considered to be significant or of concern.

iv. Ammonia, Ammonium, Nitrite, Nitrate

15E.2.44 Slightly elevated to elevated concentrations of ammonium, which exceeded the Tier 1 screening criteria, have been consistently recorded in both deep piezometers. The concentrations of ammonium recorded in CBH2_53 ranged from 0.62 to 14.16mg/l and from 1.80 to 3.85mg/l in CBH2_54. The concentrations are generally 1 – 30 times the DWS and Freshwater EQS and are therefore more significant than in the shallow aquifer. Furthermore, due to the very high pH noted in CBH2_54 (see below) the concentrations of unionised ammonia (estimated by calculation) are 66 – 142 times the conservative saltwater EQS for unionised ammonia of 0.021mg/l.

15E.2.45 The concentrations of nitrate recorded in the deep piezometers are generally similar to the shallow piezometers. Concentrations of nitrate and nitrite in the deep groundwater are consistently low in the range <1–4mg/l and <0.02mg/l respectively and are below the Tier 1 screening criteria.

v. pH Value

15E.2.46 Piezometer CBH2_53 has shown neutral pH values (ranging between pH 6.9 and 7.7 units) in comparison to the groundwater in CBH2_54 which has been consistently alkaline pH (11.7 – 12.5 units). The reason for the unusually high pH is CBH2_54 is most likely to be associated with the bedrock / deep groundwater geochemistry and may be associated with the known presence of gypsum and anhydrite nodules in the Blue Anchor formation at depth.

vi. Electrical Conductivity Values

15E.2.47 Very high electrical conductivities (88,200 -125,600µS/cm) were noted in CBH2_53 at 48m and 53m depth. However, interestingly, in situ conductivity profiling across the response zone in CBH2_53, supported by sampling and laboratory testing has demonstrated a wide variation in the electrical conductivity with depth across the response zone. The lowest value (1,821µS/cm) was noted at the top of the response zone (41mbgl) and the highest values (125,600 and 122,000µS/cm) in the middle (48m) and bottom (53m) of the response zone.

15E.2.48 Electrical conductivities in CBH2_54 were also elevated (4,780 – 7,620µS/cm) on two out of the three sampling occasions, but much less so than in CBH2_53 at 48 and 53mbgl

vii. BOD and COD

15E.2.49 BOD concentrations remained generally below the limit of detection over the two campaigns, with an exceedance of the Freshwater EQS value recorded in CBH2_54 and CBH2_53 (53 m) during the second campaign (both 8ug/l). In contrast, COD concentrations were elevated in CBH2_53 (165 – 3,494*mg/l) but not particularly in CBH2_54 (<2 – 29mg/l). *The value of 3,494mg/l is considered to be a spurious result.

viii. Suspended Solids

15E.2.50 The concentrations of suspended solids in the deep groundwater ranged from 8 – 1,040mg/l and regularly exceed the Tier 1 screening criteria (25mg/l) in both

CBH2_53 and CBH2_54. The concentrations of suspended solids varied significantly during different sampling rounds for the same piezometer.

ix. Organic Determinants (TPH, VOC, PAHs and PCB Congeners)

15E.2.51 A slightly elevated concentration of benzene at CBH2_54 (4µg/l) and CBH2_53 (53m, 2ug/l) exceeded the Tier 1 screening criteria in the second campaign. These concentrations on subsequent monitoring rounds was <1µg/l. These initial slightly elevated results are considered to be a one off results. As the concentrations were only 2-4 times the DWS, it is not considered to be significant or of concern. No other organic contaminants (i.e. TPH, VOCs, PAHs or PCBs) were present in any of the samples above the limit of detection.

x. Piezometer CBH2_54

15E.2.52 Low amounts of a light non aqueous phase liquid (LNAPL) free phase hydrocarbon product described as a thick, viscous brown oil were noted in piezometer CBH2_54 (**Figure 15.15**) by Structural Soils Limited following drilling works but prior to installation and development. Monitoring of the groundwater in this piezometer with an oil/water interface meter did not record any detectable thickness of free product, however the oil was recovered as tiny globules and streaks on the dip tape or bailer when monitored. A small amount (2ml) of the oil was recovered in May 2010 and sent to The Environmental Laboratory (Elab) for analysis. Elab's assessment and interpretation of the oil was that it was a weathered (degraded) diesel with some trace amounts of a heavier oil (>C28), which was considered likely to be lube oil. Elab aged the product at approximately 3.5 years.

15E.2.53 Piezometer CBH2_54 is a deep rotary cored borehole which was drilled to 90mbgl. No visual or olfactory evidence of hydrocarbon was noted on the borehole log. The borehole was temporarily cased to 20mbgl and shallow aquifer protection measures (as agreed with the Environment Agency) were installed during drilling to prevent any potential near surface contamination migrating downwards into the aquifer.

15E.2.54 Several rounds of 'grab samples' using dedicated hydrocarbon sampling bailers were undertaken on the non installed and developed well. The initial samples taken from just below the surface of the water column (typically approximately 4.40mbgl) in the borehole did not record any evidence of dissolved phase hydrocarbons in excess of the laboratory detection limits, however, subsequent samples taken from deeper down in the piezometer (at approximately 20mbgl i.e. just below the casing) did detect elevated concentrations of dissolved phase hydrocarbons in excess of Tier 1 screening criteria'.

15E.2.55 A series of trial pits and one window sample were excavated in close proximity around borehole CBH2_54 to see if there may be a near surface source of hydrocarbon in the area, field observations and laboratory analysis did not identify a shallow source of hydrocarbons within the made round in the immediate vicinity of CBH2-54. An additional piezometer (CBH2_55) has been drilled in close proximity to CBH2_54 to a depth of 27.60mbgl. No visual evidence of hydrocarbon was noted, however a strong hydrocarbon odour was noted in a thin band of clay at 23.1mbgl. CBH2_55 was installed with a response zone between 22.00-24.00mbgl targeting the deeper weathered clay horizon with the hydrocarbon odours. No LNAPL/free phase product has been found in CBH2_55.

15E.2.56 CBH2_54 was scheduled to be a deep monitoring piezometer and as such has been installed with a response zone from 80–90mbgl. Since the piezometer has been installed and developed, the free phase product previously present in CBH2_54 has not been noted. Furthermore, no detectable dissolved phase hydrocarbon contamination has been noted in CBH2_54 with the exception of the one sample which recorded 4µg/l of benzene on one occasion.

15E.2.57 GC-MS chromatograms of the sample of oil analysed by Elab were sent to Jones Environmental Ltd, who are a laboratory who specialise in detailed oil and hydrocarbon analysis and source identification and characterisation. Jones Environmental re-interpreted the Elab GC-MS chromatograms and concluded that the oil was most likely to be a middle distillate of indeterminate age, with no sign of biodegradation but evidence of significant weathering or water washing. The data review also indicated that the oil was unlikely to be derived from an oil shale source.

15E.2.58 Whilst the analysis would seem to confirm the source of the oil as an historic anthropogenic source, it is less clear how a LNAPL has managed to get to such a depth beneath the water table. Whilst there are mechanisms for LNAPLs to migrate to depths significantly below the water table (e.g. down dip through fractures and bedding planes etc) it usually requires a large head of free product somewhere nearby to provide the downward driving force to overcome the significant density differences. Investigations on the BDAE have not identified any significant or widespread source of free product or hydrocarbons in the shallow soils with the exception of the localised hydrocarbons around TE418 (see above) which are topographically and hydrogeologically down gradient of CBH2_54. It should be noted that naturally present oil shales are well known close to the Hinkley area (e.g. at Kilve) and similar natural oil shale type deposits could also still be an explanation for the source of the hydrocarbon noted in CBH2_54, despite the analytical results indicating the contrary. Other deep boreholes on the nearby by BDAW have occasionally noted pockets of clearly natural tar/bitumen and hydrocarbon odours at considerable depth.

15E.2.59 Monitoring of CBH2_55 located immediately upgradient of CBH2_54 and NBH03 located immediately downgradient have not detected the presence of any free or dissolved phase hydrocarbons. The presence of the small amounts of free product and dissolved phase contamination previously detected in CBH2_54 are therefore not considered to be significant or of major concern.

e) Potential Non Radiological Contaminants - BDAE

i. Shallow Groundwater

15E.2.60 There is no evidence of significant organic contamination (with respect to petroleum hydrocarbons, PCBs, PAHs and VOCs) in the shallow groundwater on the BDAE. The concentrations of metals, metalloids and other inorganics are generally low and below Tier 1 screening criteria, with the exception of a number of piezometers in the northern area of the BDAE within and downgradient of the existing mound and former NDA spoil disposal area, and former fabrication area. Piezometers in these areas have shown slightly elevated concentrations of boron, iron and various inorganic salts and occasionally ammonium. The source of this slightly elevated inorganic, metal and metalloid contamination is believed to be from the spoil and construction and demolition materials present in the mound area, similar materials present in the former NDA spoil disposal area (now removed) and the general Made Ground across the northern and north eastern area of the BDAE as a result of historical activities.

15E.2.61 Given that groundwater flow within the shallow groundwater on the BDAE is to the north north east (i.e. towards the Bristol Channel), the low to very low sensitivity of on-site groundwaters and lack of any other downgradient freshwater surface watercourses that the groundwater on the BDAE could discharge into, the Bristol Channel and associated ecology and ecosystems are considered to be the only valid potential receptors for the slightly inorganic contaminated groundwater on the northern area of the BDAE.

15E.2.62 Groundwater quality in the furthest most downgradient piezometers positioned on the northern boundary of the BDAE immediately before groundwater discharges to the Bristol Channel have shown low concentrations of these contaminants. Furthermore, the brackish water in the Bristol Channel already contains naturally elevated concentration of most of these inorganic determinands (e.g. sulphate, chloride, sodium, potassium, and boron etc), see AMEC report. The slightly elevated inorganic, metal and metalloid contamination noted in certain piezometers in the northern area of the BDAE is not therefore considered to be significant or of concern, and does not require further detailed assessment.

15E.2.63 Groundwater in the slightly deeper Blue Lias aquifer contains higher concentrations of sodium, chloride, and conductivity as well as some other metals (e.g. boron and arsenic) than the overlying shallow groundwater. This indicates that the groundwater chemistry in the Blue Lias changes with depth and in general becomes relatively more saline, with slightly higher concentrations of some metals and metalloids with depth.

15E.2.64 In the event that the ‘shallow’ groundwater in the Blue Lias is to be dewatered during the proposed construction works and then discharged either to fresh waters, or the Bristol Channel or back to shallow groundwater, an assessment of the potential impacts to these receiving controlled waters from the slightly elevated concentrations of inorganic, metal and metalloid contaminants should be made. The concentrations of suspended solids regularly exceed the surface water environmental quality standard, although this is only of environmental significance if, during construction dewatering, water containing suspended solids is discharged to a surface water receptor. Further assessment of the potential impacts to surface water as a result of potentially discharging contaminated dewatered groundwater is contained in Chapter 14 of this volume.

ii. Deep Groundwater

15E.2.65 The analysis results show that the deep groundwater is much more mineralised and exhibits a higher degree of salinity than the shallow groundwater. Concentrations of metals and metalloids above the Tier 1 screening criteria have been reported in most of the samples taken from the shallower of the deep piezometers (CBH2_53). These findings concur with the earlier investigation on the adjacent BDAW. The elevated concentrations recorded in the deeper groundwater are considered to be naturally occurring and not derived from an anthropogenic source.

15E.2.66 Given the extensive depth of the deep groundwater (i.e. >40m) it is not (under current site conditions) considered to pose a risk to other controlled waters or other environmental receptors.

15E.2.67 In the event that the deeper groundwater is to be dewatered and then discharged either to fresh waters, the Bristol Channel or back to shallow groundwater, an assessment of the potential impacts to these receiving controlled waters from the naturally elevated concentrations of various determinands and elevated suspended solids should be made.

15E.3 Southern Phase Construction Area (SCPA)

15E.3.1 The desk based assessment (**Chapter 14 of this volume**) has confirmed that the land is agricultural and has never been used for industrial purposes.

15E.3.2 Potential controlled water receptors on the SCPA include groundwater (e.g. the underlying Secondary A Aquifer) and the surface water courses that cross the site and are present along the southern boundary of the site (e.g. Bum Brook). The desk study has not identified any groundwater or surface water abstractions (e.g. boreholes and wells) on the site itself, however, there are two groundwater abstractions identified at one location 400m to the west of the SCPA.

15E.3.3 A programme of groundwater quality monitoring involving the sampling of seven piezometers (DBH2_12 –DBH2_18) installed across the SCPA has been undertaken. The locations of the piezometers are shown on **Figure 15.15**. The response zones for the seven piezometers ranged between 2 and 13mbgl and targeted shallow groundwater in either the Mercia Mudstone Group/Blue Anchor Formation or the Blue Lias. In total, three sets of samples have been collected from the piezometers on the SCPA (during the second, third and fourth campaigns).

15E.3.4 The results of the non radiological data are summarised in **Table 15E.5** (Summary of Major Ion Chemistry on the SCPA) and **Table 15E.6** (Summary of Non-Radiological Groundwater Analytical Results for the SCPA) and are discussed below. For a more detailed assessment and discussion of the non radiological and radiological groundwater quality data, the reader is referred to AMEC reports (Ref. 15E.3 and Ref. 15E.4).

a) Tier 1 Groundwater Assessment Methodology - SCPA

15E.3.5 This is described under BDAW groundwater quality above.

b) General and Major Ion Chemistry - SCPA

15E.3.6 A summary of the major ion chemistry for the SCPA is presented in **Table 15E.5.**

Table 15E.5: Groundwater Major Ion Chemistry on the SCPA

Parameter	Range Detected in Shallow Groundwater
Total Hardness (mg/l as $CaCO_3$)	367 - 614
pH Value (Units)	6.9 – 7.5
Electrical Conductivity (µS/cm)	771 – 1412

Parameter	Range Detected in Shallow Groundwater
Calcium (mg/l)	95.5 – 187.5
Magnesium (mg/l)	17.1 – 50.8
Sodium (mg/l)	13.1 – 421.6
Potassium (mg/l)	3.1 – 15.8
Ammonium (as NH_4) (mg/l)	<0.01 – 1.91
Chloride (mg/l)	26 - 396
Sulphate (mg/l)	9 - 140
Bicarbonate (mg/l as $CaCO_3$)	380 - 848
Nitrate (mg/l)	<1 - 36

Shallow Groundwater is generally intended to mean groundwater present in the Secondary A Aquifer in the underlying Blue Lias Formation and Penarth Group strata which is usually < 20m bgl,

i. Sulphate, Calcium, magnesium and potassium

15E.3.7 Major ions were recorded at typically low concentrations and below the respective Tier 1 screening criteria over the three campaigns. Exceptions to this were noted at two locations where the concentrations of magnesium exceeded the DWS in Campaign 3 for DBH2_13 (50.8mg/l) and concentrations of potassium exceeded the DWS in Campaigns 2 and 3 for and DBH2_16 (13.5 and 15.8mg/l respectively). The concentrations of potassium in DBH2_26 were relatively consistent across campaigns 2 and 3, but decreased in the fourth campaign to 7.5mg/l.

ii. Sodium and chloride

15E.3.8 Sodium and chloride concentrations exceeded the Tier 1 screening values at one of the seven piezometers (DBH2_12) in the second campaign only. No other exceedances have been recorded for these determinands and the concentrations of these parameters are low with minor variance between the piezometers observed over the three sampling campaigns.

c) Summary Major Ion Chemistry - SCPA

15E.3.9 The general major ion chemistry in the Southern Construction Phase Area shows concentrations of major ions that are considered to be consistent with natural background levels in the area.

d) Potential Groundwater Contaminants - SCPA

15E.3.10 The results of the non radiological data are summarised in **Table 15E.5** (Summary of Major Ion Chemistry on the SCPA) and **Table 15E.6** (Summary of Non-Radiological Groundwater Analytical Results for the SCPA) and are discussed below. For a more detailed assessment and discussion of the non radiological groundwater quality data, the reader is referred to the AMEC report (Ref. 15E.4**)**.

Table 15E.6: Summary of Non-Radiological Groundwater Analytical Results for the SCPA

Determinand	Units	DWS	WFD Screening Values		Range of Concentrations in Shallow Piezometers
			Saltwater EQS	Freshwater EQS	
Dissolved Arsenic*	(µg/l)	10[1] T	25[A 4 GC]	50[A 4 G15]	<1 - 2
Dissolved Cadmium*	(µg/l)	-	0.2[A 4] / 1.5 [MAC 4]	0.25[A(C5) 4] / 1.5 [MAC 4]	<0.1 - 1

Source Table B11 Environment Agency EPR H1 Environmental Risk Assessment Part 2 Assessment of point source releases and cost benefit analysis. Source Table B11 Environment Agency EPR H1 Environmental Risk Assessment Part 2 Assessment of point source releases and cost benefit analysis.

The River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2010

The Water Supply (Water Quality) Regulations 1989. N.B These Regulations were superseded by the 2000 regulations therefore there is currently no UK DWS for zinc and / or Total Petroleum Hydrocarbons.

The Surface Waters (Abstraction) for Drinking Water (Classification) Regulations 1996. DW1 treatment (i.e. simple physical treatment and disinfection) limit.

The Surface Waters (Dangerous Substances) (Classification) Regulations 1989

2006 / 44/ EC Fish Directive - Cyprinid Fish Guideline.

The Private Water Supply regulations 1992 N.B. These regulations were superseded by 2009 regulations therefore there is no current UK DWS for these determinands.

^ Guideline Value - Non statutory / proposed EQS, but EQS never adopted in UK.

DPA - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Part 7 Groundwater Threshold Values for Groundwater Drinking Water Protected Areas.

- no current threshold value available

 # - Corrected based on the reported average hardness value (399m /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

C5 - Cadmium EQS based on class 5 hardness (>200mg/l $CaCO_3$), corrected based on the reported average hardness value (399mg /l CaCO3mg/l) for the Hinkley C Drainage Ditch and the Holford Stream (258mg/l CaCO3) recorded during monitoring in 2009.

D - Dissolved

T - Total

A - Annual average

P - 95-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 5% of the time or more).

P90 - 90-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is greater than the standard for 10% of the time or more).

P5 - 5-percentile (defined as a standard that is failed if the measured value of the parameter to which the standard refers (e.g. concentration of a pollutant) is less than the standard for 5% of the time or more).

MAC Maximum Allowable Concentration

T7 - Type 7 surface water.

G15 - Threshold value based on 'good standard' to meet objective of WFD for Stogursey Brook to achieve good status by 2015.

GC - Threshold value based on 'good standard' for transitional and coastal waters to meet objective of WFD for Bridgewater Bay to achieve good ecological status by 2027 (no chemical criteria target thresholds specified).

FCN - Threshold value for free cyanide (as HCN)

H - River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 Threshold value for high standard.

$ No assessment criteria is currently available for dissolved boron and therefore the dissolved boron concentrations have been compared to total values.

** LOD   Exceedances of the annual average EQS have occurred due to the limit of detection (LOD) not being low enough. This is a consequence of applying new and lower EQS values to data obtained before the issue of these new, lower values. However, these 'exceedances' are not considered to be environmentally significant.*

DWS - Drinking Water Standard

F EQS – Freshwater Environmental Quality Standard (EQS)

n/s = not sampled as piezometers not installed, developed and / or stabilised at the time of sampling

e) Tier 1 Groundwater Risk Assessment - SCPA

i. Metals and metalloids

15E.3.11 Dissolved and total metals and metalloid concentrations recorded in the shallow groundwater were generally low. Most were recorded marginally above or below the limit of detection. Exceedances of the Tier 1 screening values were recorded for dissolved cadmium on one occasion at DBH2_16, total boron at DBH2_13 on two occasions, total iron in DBH2_13 on two occasions, dissolved zinc at four piezometers (DBH2_14, DBH2_15, DBH2_16 and DBH2_17) and total zinc at DBH2_16. High concentrations of dissolved (270 - 982µg/l) and total (374 - 1184µg/l) zinc were noted in piezometer DBH2_16 during the second and third campaigns. However, these reduced significantly by the fourth campaign. None of the groundwater samples recorded elevated concentrations of metals or metalloids above the Tier 1 screening values during the fourth campaign.

ii. Ammonia, ammonium, nitrite, nitrate

15E.3.12 Concentrations of ammonium and total ammonia in the shallow piezometers were generally low and below the Tier 1 screening values. Exceedances of the Tier 1 screening criteria for ammonium were only recorded in three of the seven piezometers (DBH2_13, DBH2_14 and DBH2_15).

15E.3.13 Nitrate concentrations ranges are generally low and none exceed the Tier 1 screening values in any of the campaigns. However, slightly elevated concentrations of nitrate (10 – 36mg/l) have been noted three of the piezometers (DBH2_12, DBH2_17, and DBH2_18). Nitrite concentrations in the shallow groundwater have been recorded below the detection limit in all three campaigns.

iii. pH Value

15E.3.14 The pH values recorded in the shallow groundwater are neutral and are highly consistent in the range 6.9 to 7.5.

iv. Electrical Conductivity Values

15E.3.15 Electrical conductivity values range from low (ranging from 771 to 1,412µS/cm but more typically 800 - 900µS/cm). None of the conductivities in the shallow groundwater exceeded the Tier 1 screening criteria.

v. BOD and COD

15E.3.16 BOD and COD were generally recorded at very low concentrations (<2 and <2 to 12mg/l respectively). During the second campaign a slightly elevated COD concentration was noted in DBH2_15 (25mg/l). BOD concentrations were below the limit of detection with the exception of in DBH2_15 and DBH2_16 during the second campaign, when concentrations exceeded the Tier 1 screening criteria (14mg/l and 8mg/l respectively).

vi. Suspended Solids

15E.3.17 The concentration of suspended solids ranged from 8 to 3,484mg/l and regularly exceeded the Tier 1 screening criteria (25mg/l) in all of the piezometers. The concentrations of suspended solids varied significantly both between locations and between sampling rounds.

vii.Organic Determinands

15E.3.18 With the exception of elevated concentrations of TPH recorded at DBH2_15 in Campaign 2, the concentrations of all organic determinands were below the detection limit.

15E.3.19 The elevated concentrations of TPH recorded in the two duplicate samples taken from DBH2_15 exceeded the Tier 1 screening criteria on the second campaign. Repeat analysis undertaken on this sample provided results below the limit of detection which indicated that a possible discrepancy and uncertainty surrounds the initial values recorded. The concentration of TPH on the third and fourth campaigns in this piezometer was below the limit of detection (<10µg/l). On this basis it is considered that the initial elevated TPH values recorded in this piezometer was a spurious result.

viii. Total and Free Cyanide

15E.3.20 Concentrations of total and free cyanide were generally below the detection limit (1µg/l) and Tier 1 screening criteria throughout the three monitoring campaigns. Exceptions to this were the total concentrations recorded marginally above the detection limit in DBH2_12 and DBH2_18 (second campaign, 3ug/l and 4ug/l, respectively) but these were still below the Tier 1 screening criteria.

15E.3.21 High concentrations of total (70 and 51µg/l) and free (5 and 3µg/l) cyanide in excess of the Tier 1 screening criteria were recorded in the two duplicate samples taken from DBH2_15 during the second campaign. Repeat analysis for total and free cyanide recorded lower (47 and 36µg/l) but still elevated total cyanide and low (<1µg/l) free cyanide. The repeat samples were below the Tier 1 screening criteria. The lower repeat results are probably the result of a degree of sample degradation whilst the samples were in storage. The initial elevated readings were not repeated during the subsequent third and fourth campaigns. This data indicates the initial elevated concentrations were an isolated occurrence.

f) Potential Non Radiological Contaminants - SCPA

15E.3.22 The shallow groundwaters across the SCPA show very little evidence of any contamination by non radiological contaminants, with the exception of very isolated and occasional occurrences of certain heavy metals, ammonia and nitrate. However these are considered to be naturally elevated and not the result of anthropogenic (man-made) contamination. The concentrations of suspended solids regularly exceed the surface water environmental quality standard, although this is only of environmental significance if, during construction dewatering, water containing suspended solids is discharged to a surface water receptor.

15E.3.23 Slightly elevated nitrate concentrations are present in some of the shallow groundwater on the SCPA. In all cases these are below the recognised environmental screening criterion of 50mg/l. The source of these slightly elevated and elevated nitrate concentrations is likely to be application of nitrogenous fertilisers or ploughing of organic-rich soils. The Hinkley Point area is a designated Nitrate Vulnerable Zone, which means that from an environmental impact assessment point of view, the groundwaters and surface waters in the area are sensitive to activities during the construction and operation of the proposed development that could give rise to nitrate pollution.

g) Groundwater Chemistry – Off-site

15E.3.24 Information on groundwater chemistry from the existing Hinkley Point Power Station sites has been obtained from documents made available for the Hinkley Point C Environmental Impact Assessment. Potential groundwater contamination on the Hinkley Point B site has not been included within the assessment due to the significant distance from the proposed Hinkley Point C site (i.e. at least 500m) and the fact that the groundwater flow directions and topographic falls in the area are generally south to north, which means that it is highly unlikely that any potential groundwater contamination on the Hinkley Point B site could affect the development site. Potential groundwater contamination on the Hinkley Point B site has therefore effectively been 'scoped out' for this baseline assessment.

15E.4 Hinkley Point A

15E.4.1 Data on groundwater quality on the Hinkley Point A site has been taken from SERCO (Ref. 15E.6). The investigations have comprised the construction of shallow boreholes, groundwater level monitoring and sampling as well as a soil investigation. The findings of the SERCO report are summarised in **Chapter 14** of this volume.

15E.4.2 The SERCO (2010) report (Ref. 15E 6) provides a summary interpretative report on land quality (soil and groundwater) at Hinkley Point A. The report comprises a collation of the land quality characterisation and monitoring programmes performed on Hinkley Point A to 1996 to June 2009. The report has been divided into two volumes, one to provide an initial over view of all land quality and monitoring data and the other to provide a more in depth appraisal.

15E.4.3 Within the SERCO report, the Hinkley Point A site 'groundwater zone' is divided into four areas as follows:

- Area 1 (east);
- Area 2 (eastern part of radiologically controlled area and turbine hall);
- Area 3 (western part of radiologically controlled area and turbine hall); and
- Area 4 (north).

15E.4.4 Groundwater generally flows south to north across the Hinkley Point A site, from about 12mAOD in the south to 4mAOD in the north. At the time of the report there were 27 extant monitoring boreholes, with 5 destroyed.

15E.4.5 Below is a brief summary of the main groundwater quality findings from the SERCO report (Ref. 15E 6).

15E.4.6 Area 1 is located in the eastern area of the Hinkley Point A site and is reported to contain two areas of potential concern (APC). APC 1 is the Active Effluent Discharge Line (AEDL)/Active Effluent Valve Pit. APC9 is the area around the Emergency Diesel Generator Building (EDGB).

15E.4.7 No non radiological contamination of any significance has been recorded in the groundwater in Area 1 with the exception of elevated hydrocarbon contamination including free product in boreholes G2B, G40, and WD6 which are located down gradient of the EDGB. Concentrations of TPH in these boreholes has frequently been measured at >10,000ug/l. Elevated TPH concentrations (~5000ug/l) have also been noted in borehole G14.

15E.4.8 Area 2 covers the central eastern area of the Hinkley Point A site and contains a number of APCs.

15E.4.9 No non radiological contamination of any significance has been recorded in the groundwater in Area 2 with the exception of slightly elevated hydrocarbon (concentrations ranging from 100-1000ug/l TPH) in some samples taken between 2004 and 2009. However, the most recent available data from January 2009, did not record any elevated TPH contamination in the boreholes in Area 2.

15E.4.10 Area 3 covers the central western area of the Hinkley Point A site and contains a number of APCs.

15E.4.11 Elevated hydrocarbon contamination has been noted in several boreholes within Area 3. The highest concentration (up to 10,000ug/l) have been noted in boreholes G36 and G37 downgradient of the West Blower House. The maximum concentrations (up to 10,000ug/l) identified in these two boreholes have been used as sources 3 and 5 in the ConSim modelling (see **Appendix 15.I**). The maximum concentration (up to 1,000ug/l) noted in G35 and G38 has been used as sources 4 and 6 in the ConSim model (see **Appendix 15.I**). A maximum concentration of 640ug/l of hydrocarbon was identified in boreholes G10. This has been used as source 7 in the ConSim modelling (see **Appendix 15.I**).

15E.4.12 Area 4 covers the northern area of the Hinkley Point A site. It has a number of APCs.

15E.4.13 Elevated TPH has been recorded in a number of boreholes in Area 4 during 2004-2009. The highest concentration (3,800ug/l) has been noted in borehole G3A on one occasion. Other elevated concentrations (up to 1,700ug/l) have been noted in boreholes G31, G32 and G33 to the north of the turbine hall. The source of the contamination is likely to be related to soil contamination associated with former transformer leaks and spills.

a) Summary Off-site

15E.4.14 Elevated hydrocarbon contamination has been noted within the groundwater at a number of locations across the Hinkley Point A site. In general the activities and concentrations have decreased significantly over the monitoring period (2004 – 2009) with most activities and concentrations being below conservative DWS limits in the most recent set of data (January 2009).

APPENDIX 15F BASELINE – DETAILED RADIOLOGICAL GROUNDWATER CHEMISTRY

[This page is intentionally left blank]

APPENDIX 15F: BASELINE – DETAILED RADIOLOGICAL GROUNDWATER CHEMISTRY

15F.1 Built Development Area West (BDAW)

15F.1.1 Five sampling campaigns for radiological analysis of groundwaters have been undertaken as part of the baseline assessment for the HPC development site. The radiological sampling campaigns coincided with the non-radiological sampling campaigns. Full analytical results are included in the Summary of Groundwater Quality Radiochemical Report (Ref. 15F.1) and summaries are provided in **Table 15F.1** below.

Samples were scheduled for laboratory analysis with the following radiochemical suite:

- High Resolution gamma spectrometry;
- Gross alpha, (calibrated with Am-241), and Gross beta, (calibrated with K-40);
- Tritium (as tritiated water); and
- Carbon-14.

15F.1.2 The suite was selected to provide a general screen for alpha, beta and gamma-emitters and to provide information with regard to soft beta-emitters (tritium and carbon-14). The inclusion of gross alpha, gross beta and tritium also meets the requirements for drinking water monitoring. The inclusion of gamma spectrometry provides quantitative data with regard to a range of natural and anthropogenic radionuclides.

15F.1.3 The Drinking Water Directive (Council Directive 98/83/EC) sets standards for drinking water quality and presents indicator parameter values for radioactivity which are not mandatory standards, but are set for monitoring purposes. If an indicator value is exceeded remedial action has to be taken only if there is a risk to human health. The following indicator parameter values are included in the Directive:

- Tritium: 100Bq/l; and
- Total indicative dose: 0.10mSv per annum, (excludes tritium, potassium-40, radon, radon decay products).

15F.1.4 The Drinking Water Directive indicator parameter values have been adopted in the United Kingdom in the Water Supply (Water Quality) Regulations 2000 (SI 3184) as amended and can be considered as screening values. Assessment of compliance with the Regulations is the responsibility of the Drinking Water Inspectorate (DWI).

15F.1.5 Monitoring of gross alpha and gross beta activity concentrations is used to screen for total indicative dose, in accordance with DWI draft guidance. If these activity concentrations are less than 0.1Bq/l and 1.0Bq/l respectively, no further investigation is needed. If either activity concentration exceeds its respective screening value, appropriate specific radionuclide analysis should be carried out and the total indicative dose calculated.

15F.1.6 A risk based approach is taken with total indicative dose providing the most restrictive measure of potential radiological contamination. A total indicative dose maximum of 0.1mSv per annum has been recommended, which is 1/10th of the Ionising Radiations Regulations 1999 (IRR99) Public Dose Limit value of 1.0mSv per annum.

15F.1.7 For the purposes of this document, threshold values derived from the Drinking Water Directive and Water Supply (Water Quality) Regulations 2000 (SI 3184) are referred to as DWI screening values.

15F.1.8 The screening values of some of the naturally occurring radionuclides measured during the study were derived from the elemental limits specified in the Radioactive Substances Act 1993 (and its replacement, Schedule 23 of the Environmental Permitting (England and Wales) Regulations 2010). The radionuclide limits were derived by the elemental limit by the number of isotopes of the element in the three natural radioactive decay series headed by uranium-238, uranium-235 and thorium-232.

Table 15F.1: Summary of Radiological Groundwater Screening Values and Background Values in the BDAW

Determinand	Screening Value			Background Values	
	EPR20101 (Bq/kg)	DWI2 (Bq/l)	WHO3 (Bq/l)	HMIP4 (Bq/l)	RIFE5 (Bq/l) (Mean and Range)
Gross Alpha (as Am-241)	NSA	0.1	0.5	0.0041 – 0.42	0.024 (0.02-0.029)

1.EPR2010 (Environmental Permitting (England and Wales) Regulations 2010) – derived threshold values for individual isotopes of the EPR2010 specified elements.

2.DWI (Drinking Water Inspectorate) - Drinking Water Directive (Council Directive 98/83/EC) sets standards for drinking water quality and presents indicator parameter values for radioactivity indicator parameter values. Have been adopted in the United Kingdom in the Water Supply (Water Quality) Regulations 2000 (SI 3184) as amended and can be considered as screening values with no regulatory status.

3.WHO (World Health Organisation) - guidance levels for radionuclides in drinking water

4.HMIP (Her Majesty's Inspectorate of Pollution) - Department of Environment Report 'Natural Radionuclides in Environmental Media. (Ref Doe/HMIP/RR/93/063).

5.RIFE (Radioactivity In Food and the Environment) Reports - the background values adopted represent the mean of the data reported in the RIFE reports 8 to 13 from 2002-2007 (RIFE 8 being the first report that includes specific data for Ashford Reservoir near Bridgwater).

NSA = No Screening Value Available

NBA = No Background Value Available

Details of analyses and results are contained in the appropriate groundwater quality campaign reports. A summary of the results is given in the paragraphs below.

a) Anthropogenic Radionuclides

15F.1.9 No anthropogenic radionuclides measurable by gamma spectrometry were detected in any of the samples throughout the sampling campaign indicating that there is no significant contamination of the groundwater in the sampling locations included in this monitoring campaign. However, the presence of anthropogenic alpha- and beta-emitting radionuclides that do not have a significant gamma-emission cannot entirely be discounted, for example, plutonium-238, 239 and 240, and strontium-90.

b) Comparison of Results with Screening Values

15F.1.10 Comparison of the gross alpha, gross beta and tritium results with the requirements of the Drinking Water Directive (Council Directive 98/83/EC) and Water Supply (Water Quality) Regulations 2000 has provided several examples of screening value exceedances. These screening value exceedances were associated with the three deep piezometer locations: CBH11, CBH16 and CBH29. CBH11 is located on the northern edge of the BDAW and is monitoring the Blue Lias. CBH16 is located in the central eastern area of the BDAW and is monitoring the Blue Anchor formation. CBH29 is located in central southern area of the BDAW and is monitoring the Blue Anchor formation. There were no examples of Drinking Water Directive (Council Directive 98/83/EC) and Water Supply (Water Quality) Regulations 2000 screening value exceedances observed for the shallow piezometers (DBH09, CBH20, CBH21, CBH24, CBH25, CBH27, CBH33 and CBH35).

c) Gross Alpha and Gross Beta at Location CBH16

15F.1.11 Sampling location CBH16 consistently provided gross beta results above the DWI screening value of 1Bq/l. The elevated gross beta values can largely be attributed to the elevated potassium-40 content of the samples. The gross beta and potassium-40 results, excluding associated uncertainties, for sampling location CBH16 are summarised in **Table 15F.2** below. Mean values for the monitoring programme are included in the table. For the purposes of this assessment, all values, including any "less than" values are included in the calculation of the mean.

Table 15F.2: Gross Beta and Potassium-40 Results for CBH16

Sampling Campaign	Gross Beta Activity Concentration (Calibrated with Potassium-40) Bq/kg	Potassium-40 Activity Concentration Bq/kg
1	4.5	4.1
2	0.6	< 1.8
3	4.6	< 2.8
4	7.8	6.6
5	6.2	5.2
Mean	4.7	4.1*

** "less than" values are included in the calculation of the mean.*

15F.1.12 Guidance in the application of the DWI screening values permits the subtraction of potassium-40 from any gross beta result that exceeds the DWI screening level. The contribution of the potassium-40 to the mean gross beta activity concentration can be calculated by multiplying the mean potassium-40 content by the negatron emission probability of potassium-40 (89.25%). The contribution of potassium-40 to the mean gross beta value is therefore 3.7Bq/kg; hence the mean gross beta excluding potassium-40 is 1Bq/kg, which is equivalent to the DWI gross beta screening value.

15F.1.13 The analytical data do not permit further analysis of the constituents of the gross beta value to be established. The absence of anthropogenic nuclides measurable by gamma spectrometry indicates that the gross beta signal is likely to be due to natural radionuclides; although the presence of anthropogenic beta-emitters that do not have a significant gamma emission, for example, strontium-90, cannot entirely be discounted.

15F.1.14 Four of the gross alpha results for CBH16 were “less than” values that exceeded the DWI screening value (0.1Bq/l). For campaign 4, a positive result was reported (5.6 ± 4.0Bq/kg) although the high relative uncertainty indicates that the result is close to the limit of detection. The high “less than” values reported for the samples from this location are due to the high dissolved solids associated with the water as indicated by the high major ion content (Ref. 15F.1).

d) Gross Alpha and Gross Beta at Location CBH29

15F.1.15 Sampling location, CBH29 provided gross beta results that were consistently close to the DWI screening value (1 Bq/l). The gross beta and potassium-40 results for sampling location CBH29 are summarised in **Table 15F.3** below.

Table 15F.3: Gross Beta and Potassium-40 Results for CBH29

Sampling Campaign	Gross Beta Activity Concentration (Calibrated with Potassium-40) Bq/kg	Potassium-40 Activity Concentration / Bq/kg
1	1.04	< 2.5
2	0.94	< 1.7
3	1.07	< 4.5
4	0.80	< 5.3
5	0.93	< 3.3
Mean	0.96	< 3.5

15F.1.16 The mean gross beta activity concentration is just below the DWI screening value (1Bq/l). In this case, it is not possible to establish whether or not that the gross beta values can largely be attributed to potassium-40 because the results for this radionuclide are all “less than” values that exceeded their associated gross beta values.

In addition, location CBH29 provided three positive gross alpha results that exceeded the DWI screening value of 0.1Bq/l but were below the WHO screening value of 0.5Bq/l. In addition, the mean gross alpha result for the monitoring programme is above the DWI screening value, but below the WHO screening value. The data are summarised in **Table 15F.4** below.

Table 15F.4: Gross Alpha Results for CBH29

Sampling Campaign	Gross Alpha Activity Concentration (Calibrated with Americium-241) Bq/kg
1	0.33
2	0.26
3	< 0.12
4	0.14
5	< 0.12
Mean	0.19*

** "less than" values are included in the calculation of the mean.*

15F.1.17 The analytical data do not permit further analysis of the constituents of the gross alpha value to be established. The absence of anthropogenic nuclides measurable by gamma spectrometry indicates that the gross alpha signal is likely to be due to natural radionuclides; although the presence of anthropogenic alpha-emitters that are not accompanied by any significant gamma emission, for example, plutonium-238, 239 and 240, cannot entirely be discounted.

e) Gross Alpha and Gross Beta at Location CBH11

15F.1.18 Sampling location CBH11 provided one gross alpha result that exceeded the DWI screening value (0.1Bq/l) in campaign 1, although based on the high relative uncertainty, the result (0.76 ± 0.71Bq/kg) was close to the limit of detection. All other gross alpha results were "less than" values that exceeded the DWI screening value.

15F.1.19 The gross beta results for CBH11 in campaigns 2 and 4 (1.39 ± 0.75 and 2.32 ± 0.96Bq/kg respectively) exceeded the DWI screening value (1Bq/l). In addition, the gross beta results for campaigns 3 and 5 were "less than" values for exceeded the DWI screening value.

15F.1.20 The analytical data do not permit further analysis of the constituents of the gross alpha and gross beta values to be established.

15F.1.21 As was the case for CBH16, the elevated gross alpha and gross beta "less than" values reported for the samples from CBH11 are due to the high dissolved solids associated with the water.

f) Tritium Results

15F.1.22 The tritium results covering the monitoring programme were all significantly below the DWI indicator parameter value of 100 Bq/l. Only three positive tritium results were reported. These were for samples DBH09, CBH25 and CBH27 from campaign 2. In each case, the results (2.5 ± 2.5, 2.6 ± 2.6 and 4.7 ± 2.8Bq/l respectively) were close to the limit of detection and were of the same order of magnitude as the adopted RIFE (Radioactivity in Food and the Environment) background value (< 4.0Bq/l).

g) Naturally Occurring Radionuclides

15F.1.23 Naturally occurring radionuclides detected in any of the samples throughout the monitoring programme were carbon-14, potassium-40, lead-214, bismuth-214 and lead-212.

15F.1.24 Carbon-14 was detected in sample CBH11 in campaign 2 at a level close to the limit of detection (4.9 ± 4.6Bq/kg) and significantly below the WHO guidance value (100Bq/l).

15F.1.25 Potassium-40 was detected in samples from location CBH16 in campaigns 1, 4 and 5. Its presence makes a significant contribution to the elevated gross beta results observed for this sample location.

15F.1.26 Bismuth-214 and lead-214 were detected in a number of samples throughout the monitoring programme. These radionuclides are decay products of radon-222; hence in accordance with the Drinking Water Directive (Council Directive 98/83/EC), these radionuclides are excluded from the assessment of total indicative dose. This exclusion also applies to lead-212, which is a decay product of radon-220.

h) BDAW - Non-technical Summary

15F.1.27 The groundwater monitoring programme in the Built Development Area West provided no evidence to suggest that the groundwater was contaminated with significant levels of anthropogenic radionuclides. All of the shallow groundwaters meet the water quality requirements of the Water Supply (Water Quality) Regulations 2000 i.e. the gross alpha, gross beta and tritium levels are below 0.1, 1 and 100Bq/l respectively. The deep groundwaters contained elevated levels of gross beta, which in some cases exceeded the 1Bq/l limit; however, these elevated levels were attributable to the presence of the naturally occurring radionuclide, potassium-40 and is such is not considered significant.

15F.1.28 The shallow and deep groundwaters on the BDAW have not been found to contain any radiological contamination of concern.

15F.2 Built Development Area East (BDAE)

15F.2.1 As outlined above, an extensive programme of groundwater quality monitoring (similar in size and scope to that conducted on the BDAW above) has been conducted on the BDAE. This has involved sampling twenty one piezometers on at least three occasions (thirteen of the piezometers have been sampled on four occasions). Four of the piezometers (DBH2_10, DBH2_21, DBH2_22 and DBH2_27) have been installed along the eastern boundary of the BDAE to monitor for potential cross boundary groundwater contaminant migration from the adjacent Hinkley Point A power station complex.

15F.2.2 Groundwater samples were analysed for the same as for the BDAW above:

- Gross alpha (calibrated with americium-241) and gross beta (calibrated with potassium-40);
- Tritium (as tritiated water);
- High-resolution gamma spectrometry; and
- Carbon-14.

The results of the radiological data are summarised and discussed below.

15F.2.3 In the following sections, the term ‘’positive value’’ relating to a particular determinand is used to indicate that it has been detected and the term “less than” value is used to indicate that the determinand is below a reporting limit.

a) Gross Alpha Activity

15F.2.4 Positive gross alpha results have been reported at seven of the sample locations (DBH2_8, DBH2_9, DBH2_20, DBH2_21, DBH2_23, CBH2_56 and CBH2_57). Positive results that exceeded the DWI screening value (0.1 Bq/l), but were below the WHO screening value (0.5Bq/l) were observed at two of these seven sample locations (DBH2_9 and CBH2_56) in Campaign 3 (0.14 ± 0.11 and 0.124 ± 0.071 Bq/kg respectively). However during Campaigns 2 and 4, the results for DBH2_9 were 0.068 ± 0.059 and < 0.071Bq/kg respectively. For CBH2_56, the Campaigns 2 and 4 results were < 0.067 and 0.049 ± 0.046Bq/kg respectively. Samples were not collected from DBH2_9 and CBH2_56 during Campaign 1. The results for the groundwater monitoring programme indicate that groundwater sampled from locations DBH2_9 and CBH2_56 have not consistently exceeded the DWI screening value (0.1Bq/l).

15F.2.5 There have been eighteen cases of gross alpha results being reported as “less than” values that exceed the DWI screening value (0.1Bq/l). The “less than” values reported for CBH2_53 in Campaigns 2, 3 and 4 (< 2.4, < 1.9 and < 1.4Bq/kg respectively) also exceeded the WHO screening value (0.5Bq/l). The elevated “less than” values reported are due to elevated levels of dissolved solids in the sample which detrimentally affects the limit of detection achievable for the analytical method.

b) Gross Beta Activity

15F.2.6 Positive gross beta results have been reported for all of the samples. There have been gross beta results for four sample locations which have exceeded the DWI and WHO screening value (1Bq/l): CBH2_53 (deep groundwater) in Campaigns 2, 3 and 4; DBH2_9 in Campaigns 2, 3 and 4; CBH2_54 (deep groundwater) in Campaigns 2 and 4; and DBH2_7 in Campaigns 3 and 4. Samples were not collected from locations CBH2_53, CBH2_54 and DBH2_9 during Campaign 1. The gamma spectrometry results provide no evidence of the presence of anthropogenic radionuclides and it is therefore likely that the elevated gross beta values are due to the naturally occurring radionuclide potassium-40, although this could not be confirmed from the radiochemical analyses because the measured potassium-40 results associated with the gross beta exceedances are “less than” values. However, the beta (negatron) activity concentration due to potassium-40 can be calculated from the potassium concentration using a beta activity concentration for natural potassium of 27.4Bq/g. **Table 15F.5** provides a comparison of the beta activity concentration of potassium-40 calculated from the measured potassium concentration (Ref.15F.2) with the measured gross beta activity concentration for samples that exceeded the DWI and WHO screening value.

Table 15F.5: Comparison of Calculated Potassium-40 Beta with Measured Gross Beta for Samples from BDAE that Exceed the DWI and WHO Screening Value

Sample Location	Campaign	Potassium Result mg/l	Calculated K-40 Beta Activity Concentration Bq/l	Measured Gross Beta Activity Concentration Bq/kg
CBH2_53	Campaign 2	213.4	5.8	4.8 ± 2.1
	Campaign 3	236.1	6.5	3.7 ± 2.0
	Campaign 4	186.3	5.1	2.5 ± 1.2
DBH2_9	Campaign 2	98.5	2.7	3.18 ± 0.25
	Campaign 3	351.4	9.6	5.01 ± 0.42
	Campaign 4	235.2	6.4	3.57 ± 0.31
CBH2_54	Campaign 2	78.2	2.1	1.85 ± 0.23
	Campaign 4	28.0	0.77	1.62 ± 0.16
DBH2_7	Campaign 3	29.1	0.80	2.82 ± 0.34
	Campaign 4	27.5	0.75	1.09 ± 0.26

15F.2.7 The beta activity concentrations due to potassium-40 calculated from the potassium concentrations generally show that the elevated gross beta results can be attributed to the potassium-40 content. Guidance in the application of the DWI screening values permits the subtraction of potassium-40 from any gross beta result that exceeds the DWI screening level (1Bq/l). With one exception (Campaign 3: DBH2_7), subtraction of the calculated potassium-40 beta activity concentration from the gross beta results in gross beta results below this screening level.

15F.2.8 The Campaign 3 DBH2_7 gross beta result (2.82 ± 0.34Bq/kg), which is not largely accounted for by the calculated potassium-40 content, is significantly higher than the results for Campaigns 1 and 2 (0.38 ± 0.11 and 0.41 ± 0.18Bq/kg respectively), which were below the DWI and WHO screening value (1Bq/l). The Campaign 4 result for DBH2_7 exceeds the DWI and WHO screening values, but it is largely attributable to the presence of potassium-40 and is therefore not considered to be significant or of concern.

c) Tritium

15F.2.9 Tritium has been detected in the shallow groundwater at several locations (DBH2_9, DBH2_8, DBH2_10, DBH2_23 DBH2_24, DBH2_26 CBH2_56, CBH2_57 and NBH04,) across the BDAE. The positive results reported for DBH2_9 (Campaign 4: 2.6 ± 2.5Bq/l), DBH2_23 (Campaign 4: 2.6 ± 2.5Bq/l); DBH2_10 (Campaign 2: 2.5 ± 2.4Bq/l), DBH2_8 (Campaign 4: 2.8 ± 2.5Bq/l), DBH_24 (Campaign 2: 2.8 ± 2.6Bq/l) and NBH04 (Campaign 4: 3.7 ± 2.5Bq/l) were close to the limit of detection based on the high relative uncertainty reported and were below the upper limit of the adopted RIFE background range (< 4Bq/l). All of the detected tritium activities were below the DWI screening value (100Bq/l).

15F.2.10 Tritium was detected in all of the samples collected from CBH2_57 (Campaign 2: 14.9 ± 1.3Bq/l; Campaign 3: 29.3 ± 3.5Bq/l and Campaign 4: 8.4 ± 2.8Bq/l) at levels above the upper limit of the adopted RIFE background range (< 4 Bq/l), but significantly below the DWI screening value (100Bq/l). Tritium was also detected in three of the four samples collected from DBH2_26 (Campaign 1: 12.5 ± 2.6Bq/l; Campaign 3: 13.0 ± 2.8Bq/l and Campaign 4: 4.5 ± 2.6Bq/l) at levels above the upper limit of the adopted RIFE background range. The Campaign 2 result for DBH2_26 was a positive result (2.6 ± 2.5Bq/l) at a level close to the limit of detection. For CBH2_56, the Campaign 3 result (4.7 ± 2.4Bq/l) exceeded the adopted RIFE background value (<4Bq/l). The other results for this sample location were positive (Campaign 2: 3.0 ± 2.5 Bq/l and Campaign 4: 3.8 ± 2.5Bq/l), but were below adopted RIFE background value.

15F.2.11 The three monitoring boreholes (CBH2_56, CBH2_57 and DBH2_26) where tritium has been detected at levels above the upper limit of the adopted RIFE background range (<4Bq/l) below the DWI screening value (100Bq/l) are located in the north-east of the BDAE close to the Hinkley Point A site boundary.

15F.2.12 All other tritium results were reported as “less than” values falling within the range <1.8 to < 4.0Bq/l.

d) Anthropogenic Radionuclides

15F.2.13 No anthropogenic radionuclides measurable by high-resolution gamma spectrometry have been detected at any of the sample locations during the monitoring programme.

15F.2.14 For all of the samples, the reported “less than” values for cobalt-60 were below the upper limit of the RIFE background range (<1.1Bq/l).

15F.2.15 With four exceptions (DBH2_23 <1.4Bq/kg in Campaign 2; DBH2_10 <1.1Bq/kg in Campaign 1; and CBH2_56 <1.3Bq/kg and DBH2_26 <1.5Bq/kg in Campaign 3) the “less than” values reported for caesium-134 were below the upper limit of the RIFE background range (<0.97Bq/l).

15F.2.16 For all of the samples, the reported “less than” values for caesium-137 were below the upper limit of the RIFE background range (<0.86Bq/l).

15F.2.17 With one exception (DBH2_24 <1.2Bq/kg in Campaign 4, the “less than” values reported for americium-241 were below the upper limit of the WHO screening value for americium-241 (1Bq/l).

15F.2.18 There have been nine neptunium-237 results (DBH2_10 in Campaign 4, DBH2_22 in Campaign 4, DBH2_27 in Campaigns 2 and 4, DBH2_7 in Campaign 4, DBH2_8 in Campaign 3, DBH2_24 in Campaign 4 and NBH04 in Campaigns 1 and 4) reported as “less than” values that exceeded the WHO screening value for neptunium-237 (1Bq/l). The highest “less than” value reported was for the sample from DBH2_7 (<2.4Bq/kg).

e) Naturally Occurring Radionuclides

15F.2.19 Lead-214 and lead-212 are the only naturally occurring radionuclides measurable by high-resolution gamma spectrometry detected in any of the samples to date. Lead-214 was detected in one sample (DBH2_19 0.64 ± 0.42Bq/kg in Campaign 4) at a level close to the limit of detection based on the high relative uncertainty reported and below the screening value derived from EPR2010 (0.93Bq/kg). Lead-212 was detected in five samples in Campaign 2 (CBH2_30, DBH2_27, DBH2_7, DBH2_24 and NBH_04) at levels close to the limit of detection based on the high relative uncertainty reported. The results ranged from 0.25 ± 0.19 to 0.39 ± 0.21Bq/kg, which is below the screening value derived from EPR2010 (0.93 Bq/kg). Lead-214 and lead-212 are decay products of radon-222 and radon-220 respectively; hence in accordance with the Drinking Water Directive (Council Directive 98/83/EC), is excluded from the assessment of total indicative dose.

15F.2.20 All of the results for lead-210 and radium-226, have been reported as "less than" values that have exceeded their respective WHO screening values (0.1 and 1Bq/l). In many cases, the protactinium-234 results have been reported as "less than" values that have exceeded their EPR2010 screening value (11.1Bq/kg). All uranium-235 results have been reported as "less than" values that have exceeded the adopted RIFE background value (<0.010Bq/l) but were below the WHO screening value (1Bq/l). There have also been twenty-two potassium-40 results reported as "less than" values that exceeded the upper limit of the HMIP background range (3.6Bq/l). There are two lead-214 results reported as a "less than" values that exceeded the EPR 2010 screening value (0.93Bq/kg) and one thorium-234 result reported as a "less than" values that exceeded the EPR 2010 screening value (6.2Bq/kg). Reportable "less than" values for naturally occurring radionuclides, including potassium-40, protactinium-234m, radium-226, lead-210, lead-214, bismuth-214 etc, may be elevated because these nuclides are inherently present in the background at levels that can be subject to variation over time; hence, the uncertainty associated with correcting results for the background can be relatively high.

f) Carbon-14

15F.2.21 With one exception in Campaign 3 (CBH2_55: 7.2 ± 7.0Bq/kg), the carbon-14 results reported were "less than" values falling in the range <2.3 to <16 Bq/kg. Based on the high reported relative uncertainty, the positive result is close to the limit of detection. In all cases, the results were below the WHO screening value for carbon-14 (100 Bq/l).

g) BDAE – Non-technical Summary

15F.2.22 The radiochemical analysis results for the groundwater monitoring programme for the Built Development Area East indicate that the groundwater sampled and analysed is not significantly contaminated with anthropogenic radionuclides, and would not present a hazard to human health or be of concern based on a comparison against the public dose limit of 1mSv per annum. Overall, it is therefore unlikely that, the groundwaters would exceed the total indicative dose (committed effective dose) threshold value of 0.1mSv per annum if they were to be consumed as drinking water.

15F.2.23 Slightly elevated levels of tritium above the adopted RIFE background value (<4Bq/l) have been detected at three locations (CBH2_56, CBH2_57 and DBH2_26) in the north-east of the Built Development Area East close to the Hinkley Point A site boundary. However, the activities are below the drinking water screening level of (100Bq/l) and as such are not significant or of concern.

15F.2.24 Under current radioactive substances regulation (permitting regulations EPR2010) there is no de-minimus for man-made radionuclides such as tritium in aqueous solutions where they become a waste (e.g. dewatered groundwater requiring disposal) and as such, currently are not exempt from these regulations. However, this legislation is due to change in the near future (October 2011) (Ref. 15F.3). It will then be likely that the levels of tritium found in groundwater water pumped from these areas (i.e. (CBH2_56, CBH2_57 and DBH2_26) during the planned dewatering during construction, will in future become exempt from radioactive substances regulation if it is considered to be a waste material.

15F.3 Southern Construction Phase Area (SCPA)

15F.3.1 As stated above, a programme of groundwater monitoring involving sampling from seven piezometers on three occasions has been undertaken on the SCPA during 2010. The results of the radiological analysis of the groundwater samples on the SCPA are summarised below.

15F.3.2 Groundwater samples were analysed for the same parameters as for the BDAW and BDAE which included:

- Gross alpha (calibrated with americium-241) and gross beta (calibrated with potassium-40);
- Tritium (as tritiated water);
- High-resolution gamma spectrometry; and
- Carbon-14.

a) Gross Alpha Activity

15F.3.3 Positive gross alpha results have been reported at five of the seven sample locations to date (DBH2_12, DBH2_14, DBH2_16, DBH2_17 and DBH2_18). Gross alpha results that exceed the DWI screening value (0.1Bq/l), but are below the WHO screening value (0.5Bq/l) have been reported for two of the sample locations (DBH2_12 and DBH2_17). The Campaign 2 result for DBH2_12 was 0.117 ± 0.049Bq/kg. The other gross alpha results for this sample location (Campaign 3: 0.096 ± 0.048Bq/kg and Campaign 4: 0.052 ± 0.044Bq/kg) are at or below the DWI screening value. The Campaign 3 result for DBH2_17 was 0.141 ± 0.057Bq/kg. The other gross alpha results for this sample location (Campaign 2: 0.099 ± 0.049Bq/kg and Campaign 4: 0.080 ± 0.044Bq/kg) are at or below to the DWI screening value. The mean gross alpha results (excluding uncertainties) for sample locations DBH2_12 and DBH2_17 are 0.088 and 0.107Bq/kg respectively; the latter value being marginally above the DWI screening value (0.1Bq/l), but below the WHO screening value (0.5Bq/l).

b) Gross Beta Activity

15F.3.4 Positive gross beta results have been reported for all of the samples to date. The results have ranged from 0.072 ± 0.024 to 0.424 ± 0.048Bq/kg, which are below the DWI and WHO screening value (1Bq/l). The highest result reported was for sample DBH2_16 for Campaign 3.

c) Tritium

15F.3.5 With two exceptions, the tritium results were reported as “less than” values falling within the range <1.8 to <3.9Bq/l. The two positive tritium results were reported for sample DBH2_16 for Campaign 2 (2.1 ± 1.9Bq/l) and sample DBH2_14 for Campaign 4 (2.7 ± 2.2Bq/l). These positive results are at a level close to the limit of detection based on the high relative uncertainty reported. All of the results are significantly below the DWI screening value (100Bq/l) and are below the upper limit of the adopted RIFE background range (<4Bq/l).

d) Anthropogenic Radionuclides

15F.3.6 No anthropogenic radionuclides measurable by high-resolution gamma spectrometry have been detected to date at any of the sample locations.

15F.3.7 For all of the samples, the reported “less than” values for cobalt-60 were below the upper limit of the RIFE background range (<1.1Bq/l).

15F.3.8 With one exception in Campaign 2 (DBH2_12: <2.4Bq/kg), the “less than” values reported for caesium-134 were below the upper limit of the RIFE background range (<0.97Bq/l).

15F.3.9 For all of the samples, the reported “less than” values for caesium-137 were below the upper limit of the RIFE background range (<0.86Bq/l).

15F.3.10 With one exception (DBH2_14: <1.1Bq/kg in Campaign 4), the americium-241 results reported were “less than” values that were below the WHO screening value for americium-241 (1Bq/l).

15F.3.11 With four exceptions (DBH2_13: <1.3Bq/kg in Campaign 2, DBH2_12: <2.5Bq/kg in Campaign 4, DBH2_14: <1.6Bq/kg in Campaign 4 and DBH2_15: <1.5Bq/kg in Campaign 4), the neptunium-237 results reported were “less than” values that were below the WHO screening value for neptunium-237 (1Bq/l).

e) Naturally Occurring Radionuclides

15F.3.12 No naturally occurring radionuclides have been detected in any of the samples. All of the results for lead-210 and radium-226, have been reported as “less than” values that have exceeded their respective WHO screening values (0.1 and 1Bq/l). In many cases, the protactinium-234 results have been reported as “less than” values that have exceeded their EPR2010 screening value (11.1Bq/kg). All uranium-235 results have been reported as “less than” values that have exceeded the adopted RIFE background value (<0.010Bq/l) but were below the WHO screening value (1Bq/l). There have been eight potassium-40 results reported as “less than” values that exceeded the upper limit of the HMIP background range (3.6Bq/l). There has also been one lead-214 result that exceeded the EPR 2010 screening value (0.93Bq/kg). Reportable “less than” values for naturally occurring radionuclides, including potassium-40, protactinium-234m, radium-226, lead-210, lead-214, bismuth-214 etc, may be elevated because these nuclides are inherently present in the background at levels that can be subject to variation over time; hence, the uncertainty associated with correcting results for the background can be relatively high.

f) SCPA – Non-technical Summary

15F.3.13 The radiochemical analysis results for the groundwater monitoring programme for the SCPA indicate that the groundwater sampled and analysed is not contaminated with anthropogenic radionuclides, and would not present a hazard to human health or be of concern based on a comparison against the public dose limit of 1mSv per annum. Overall, it is therefore unlikely that, the groundwaters would exceed the total indicative dose (committed effective dose) threshold value of 0.1mSv per annum if they were to be consumed as drinking water.

15F.4 Hinkley Point A

15F.4.1 As previously discussed, data on groundwater quality on the Hinkley Point A site has been taken from the SERCO and Golder reports made available to AMEC (Ref. 15F.4, Ref.15F.5, Ref. 15F.6, Ref. 15F.7, Ref 15F.8).

15F.4.2 Groundwater samples were analysed for gross alpha, gross beta and tritium, with Sr-90 in five selected boreholes.

15F.4.3 Within the SERCO report (Ref. 15F.4) the Hinkley Point A site 'groundwater zone' is divided into four areas and results are presented below for each area.

a) Area 1

15F.4.4 Area 1 is located in the eastern area of the Hinkley Point A site and is reported to contain two areas of potential concern (APC).

15F.4.5 Gross alpha activity was below the World Health Organisation Drinking Water Standard (WHO DWS) of 0.5Bq/l in all samples between 2004 -2009.

15F.4.6 Gross beta activity was below the WHO DWS of 1Bq/l in all the boreholes with the exception of one borehole (G22) which recorded slightly elevated levels (1.7Bq/l) in 2005, but which was less than the WHO DWS of 1Bq/l in 2009.

15F.4.7 Tritium activities in groundwater are typically <20 Bq/l with the exception of boreholes G17, G24, and G25 which show slightly elevated tritium activities (up to 42Bq/l). The slightly elevated activities are located down gradient of the AEVP which may be the source. However, all the recorded tritium activities are well below the UK DWS of 100Bq/l.

b) Area 2

15F.4.8 Area 2 covers the central eastern area of the Hinkley Point A site and contains a number of APCs.

15F.4.9 Gross alpha activity was below the WHO DWS of 0.5Bq/l in all samples between 2004 -2009

15F.4.10 The majority of monitoring boreholes in Area 2 have recorded gross beta activities less than the WHO DWS of 1Bq/l with the exception of borehole G9 which has shown activities ranging from 2 - 8Bq/l between 2004 – 2009. The beta activity in this location has however shown a definite downward trend over the monitoring period and when last monitored in early 2009 was 3.3Bq/l.

15F.4.11 Tritium activities in groundwater in the area are typically <100Bq/l with the exception of borehole G13 which has regularly detected elevated tritium ranging from 100 to 800Bq/l. The tritium levels in this borehole have shown an overall downward trend from 2004 -2009.

c) Area 3

15F.4.12 Area 3 covers the central western area of the Hinkley Point A site and contains a number of APCs.

15F.4.13 Gross alpha activity has been below the WHO DWS of 0.5Bq/l in the majority of boreholes in Area 3 with the exception of one elevated sample (0.5 to 2.0Bq/l) in borehole G7. However the alpha activity in this borehole in the most recent sampling (January 2009) was below the WHO DWS of 0.5Bq/l.

15F.4.14 Gross beta activity above the WHO DWS of 1 Bq/l has been noted in borehole G6 (2 to 14Bq/l) between 2004 and 2009. Based on these results, and the range of concentrations as indicated on the Figure on page 89 of the SERCO report (Ref. 15F.4), a conservative activity of 20 Bq/l has been assumed for G6 which is source 1 in the ConSim modelling (see **Appendix 15.I**). This borehole is located downgradient of the R2 Flask Washdown Bay. The gross beta activity in borehole G6 in the latest set of available results (January 2009) was still elevated (6Bq/l). Slightly elevated gross beta activities (1 to 3Bq/l) were also noted in borehole G7 which is near to one of the cooling ponds. Borehole G34 recorded gross beta activities of 4Bq/l on one occasion.

15F.4.15 Elevated tritium activities have also been noted in several of the boreholes in Area 3 between 2004 - 2009. The highest activities (1910, 1850 and 1520Bq/l) were noted in boreholes A6, G7 and G35 downgradient of the decontamination building and R2 cooling pond, respectively. The activities have since decreased sharply, with the activity in borehole G7 (269Bq/l) only remaining above the UK DWS of 100Bq/l in January 2010.

d) Area 4

15F.4.16 Area 4 covers the northern area of the Hinkley Point A site. It has a number of APCs.

15F.4.17 Gross alpha activity has been recorded above the WHO DWS of 0.5Bq/l in three boreholes within Area 4 between 2004 - 2009. However the alpha activities in all boreholes in the most recent sampling (January 2009) were below the WHO DWS of 0.5 Bq/l.

15F.4.18 Gross beta activity is generally elevated in boreholes close to the sea wall, however this is not believed to be from a manmade source on the HPA rather from seawater (which contains naturally levels of the beta emitting radionuclide K-40).

15F.4.19 Tritium activities across the area have all been below the UK DWS of 100Bq/l.

e) Additional Routine Groundwater Monitoring (July 2009 – August 2010)

15F.4.20 A routine groundwater quality monitoring programme has been undertaken on the Hinkley Point A site by Golder Associates (GA) on behalf of Magnox South between July 2009 and August 2010 and the data for this has been presented factually in the monitoring reports.

15F.4.21 During the GA groundwater monitoring visits, a similar groundwater monitoring well network to that previously sampled by SERCO was used, except in August 2010 when the borehole network was extended following a supplementary investigation which was undertaken in accordance with the recommendations made in the SERCO report (Ref. 15F.4). Groundwater samples collected during the routine monitoring visits were analysed for a range of radiochemical and non-radiochemical determinands.

15F.4.22 A review of the analytical data recorded during the additional routine monitoring programme indicates that the radiochemical and non-radiochemical contaminant concentrations are generally similar to those recorded during the previous monitoring undertaken by SERCO and that no new source of contamination has been identified in the groundwater. The highest concentrations of tritium recorded over the three monitoring visits were in the range 89.5 to 438Bq/l which were recorded at borehole G35 (located towards the western boundary of the Hinkley Point A site). The highest Strontium-90 concentrations were in the range 1.58 to 2.78Bq/kg, with the highest value recorded at borehole G9 which is located in the central southern area of the Hinkley Point A site.

15F.4.23 The concentrations of non-radiochemical determinands recorded during the GA monitoring visits were also similar to the data range recorded previously by SERCO, although notable concentrations of speciated hydrocarbon fractions (speciated TPH working group criteria) have been recorded on the January and August 2010 monitoring visits conducted. Elevated hydrocarbon fraction concentrations were recorded at boreholes G1A and G22 (July 2010) in the range 1040 – 3890µg/l and G4A and G36 (August 2010) in the range 1550 and 4460µg/l.

15F.4.24 Very elevated concentrations of dissolved speciated hydrocarbon fractions (various aliphatic and aromatic fractions) were recorded at G2B (141mg/l) in August 2010, which is located close to the eastern boundary of the Hinkley Point A site and at a distance which exceeds that of the modelled maximum zone of influence associated with construction dewatering on the proposed Hinkley Point C site. Although not discussed directly in the factual report, free phase product has been recorded at G2B which may have influenced the dissolved concentrations recorded in the sample recovered from this borehole. Samples of groundwater were not previously taken from this borehole because free phase product had been detected.

15F.4.25 Analytical data for the ‘new’ shallow boreholes included in the monitoring network (August 2010) show relatively low concentrations of inorganic and organic contaminants which are generally consistent with those recorded in the groundwater at other boreholes. Detectable concentrations of speciated hydrocarbons were recorded at G42A (328µg/l), G45B (18µg/l) and G46 (92µg/l).

15F.5 Hinkley Point B

15F.5.1 Potential radiological groundwater contamination on the Hinkley Point B site has not been included given the large distance (>500m) from the Hinkley Point B site to the development site and known groundwater flow directions being south to north (i.e. not towards the development site from the Hinkley Point B site), any radiological groundwater contamination on the B station site has been ‘scoped out’.

APPENDIX 15H DETAILED GROUNDWATER MODEL CALIBRATION

[This page is intentionally left blank]

APPENDIX 15H: DETAILED GROUNDWATER MODEL CALIBRATION

15H.1 Introduction

15H.1.1 This appendix details the process through which the MODFLOW groundwater model was calibrated. This process started with a sensitivity analysis to determine the most sensitive parameters on which the calibration was focused to begin with, followed by a steady state and several transient calibrations as detailed below. The transient calibrations utilised both on-shore pumping test data and calibration against annual rainfall recharge. The transient calibrations were based on the initial steady state calibration.

15H.2 Sensitivity Analysis

15H.2.1 A sensitivity analysis using the Groundwater Vistas 'auto-sensitivity' functionality was performed to determine the most sensitive parameters in the model, and also those that are insensitive and were therefore set at fixed values initially. The parameters assessed were Kx, Ky, and Kz for all zones and layers in the model. Note that in Groundwater Vistas, anisotropy between Kx and Ky cannot be separately assessed in either auto-sensitivity or auto-calibration modes. This requires additional manual calibration steps to be performed if any horizontal anisotropy is required in the model.

15H.2.2 **Table 15H.1** details the parameters used for the sensitivity analyses.

Table 15H.1: Model Sensitivity Analysis Values

Parameter	Layer	Base Value (m/d)	Range
Kx (=Ky)	1	0.19	+/- half an order of magnitude for each (1 order of magnitude in total for each)
Kx (=Ky)	2	0.0039	
Kx (=Ky)	3	4.41	
Kx (=Ky)	4	0.0432	
Kx (=Ky)	5	0.0432	
Kz	1	0.00086	
Kz	2	4.00E-06	
Kz	3	0.001	
Kz	4	4.00E-05	
Kz	5	0.0002	

15H.2.3 **Figure 15.H.1** shows the sensitivity analysis results in terms of average head change across the model domain in response to the parameter change in question. Average head change is a calculation performed by Groundwater Vistas and is a summary of the average head change in each cell for each layer in response to the change in each parameter from the head at the start of the simulation. The permeability results in **Figure 15.H.1** show that the Kx and Ky for Layers 1 and 3 in the model are by far the most sensitive, with Kx, Ky and Kz for all other layers being relatively insensitive.

The steady state calibration process described below therefore focused on Kx and Ky in Layers 1 and 3 initially.

15H.3 Steady State Calibration

15H.3.1 An initial calibration was undertaken under steady state conditions (i.e. without any time-variant factors) with the aim of establishing a preliminary match of the observed patterns of groundwater flow and fitting to specific target boreholes where possible. The target data used for this calibration step are shown in **Table 15H.2**. These data are dip levels from BDAW boreholes from January 2010, and are the most complete dataset were available that represent peak water levels. Dip levels taken across the site (BDAW, BDAE and SCPA) in December 2010 show levels several metres lower than the January 2010 data (2010 being a relatively dry rainfall year). It is important to use peak water levels as target data for this stage of the calibration so that an estimate of peak rainfall recharge can be made. The transient model (see below) was based on this steady state model and was begun during a period of high rainfall (January 2010) and therefore high groundwater heads. This approach allowed an appropriate steady state stress period for the start of the transient model to be achieved.

Table 15H.2: Steady State Calibration Targets

Borehole	Response Zone	Target Head (mAOD)
CBH09	Blue Anchor (layer 5)	7.17
CBH10	Blue Lias (layer 1/2)	16.27
CBH11	Blue Lias (layer 1/2)	11.86
CBH16	Blue Anchor (layer 5)	12.11
CBH17	Blue Lias (layer 1/2)	13.28
CBH18	Blue Lias (layer 1/2)	13.11
CBH21	Blue Lias (layer 1/2)	14.04
CBH24	Blue Lias (layer 1/2)	11.58
CBH25	Blue Lias (layer 1/2)	20.22
CBH26	Blue Lias (layer 1/2)	14.42
CBH27	Blue Lias (layer 1/2)	17.02
CBH29	Blue Anchor (layer 5)	6.63
DBH05	Westbury (layer 4)	6.94
DBH06	Blue Lias (layer 1/2)	11.47
DBH07	Blue Lias (layer 1/2)	12.87
DBH08	Blue Lias (layer 1/2)	13.59
DBH09	Blue Lias (layer 1/2)	14.96
DBH10	Blue Lias (layer 1/2)	17.32

15H.3.2 The steady state model calibration is shown in **Figure 15.H.2** to **Figure 15.H.6** for model Layers 1 to 5 respectively. The residual heads for the final calibrated steady state model are shown in **Figure 15.H.7**. **Figure 15.H.8** shows a plot of observed versus simulated model heads.

15H.3.3 The January 2010 targets in **Table 15H.2** are spread over Layers 1, 4 and 5, with the vast majority being in Layer 1. The calibration for Layer 1 (**Figure 15.H.2**) is very good with the majority of computed heads in the model within 1-2 metres of their respective targets (**Figure 15.H.7**). However for the deeper layers (Layers 4 and 5), the residual heads are larger (**Figure 15.H.7**). This could be due to changes in salinity with depth. This is most obvious in borehole CBH16 which is hypersaline (approximately three times more saline than seawater). As seawater is denser than freshwater, the equivalent head will be higher than the observed heads. Calculations for this borehole suggest that this head may be depressed by between 3.6 and 7m which would act to make the calibration of Layer 5 even more difficult to achieve. Furthermore, the CBH16 groundwater conductivity of 150,000µS/cm suggests strongly that this is not part of a groundwater regime that could be considered 'active' in the context of the model, even within the low permeability of Layer 5. If it were more active, the hypersaline water would have dissipated over time. It was therefore decided to remove CBH16 from the target dataset for this model as the disparity of the head for this borehole compared to its neighbour (CBH09) cannot be accounted for in the model.

15H.3.4 The calibrated heads and residuals in Layer 1 (**Figure 15.H.2** and **Figure 15.H.7**) do not show any broadly discernible patterns with regards to the distribution of positive and negative residual heads which suggests that there are no medium to large scale influences due to spatial recharge, permeability or faults that are not incorporated in the model.

15H.3.5 It should also be noted that the sensitivity analysis detailed above showed that the sensitive geological parameters in the model are Kx and Ky in Layers 1 and 3. The parameters associated with Layers 4 and 5 are insensitive and the calibration process discussed here therefore only indirectly affected heads in Layers 4 and 5, to begin with.

15H.3.6 **Table 15H.3** shows the calibrated steady state parameters achieved through several calibration iterations focussing on Kx and Ky in Layers 1 and 3 (the sensitive parameters and layers).

15H.3.7 It was decided to remove borehole DBH04 from the target dataset as the hydrograph showed no head response over the monitoring period. It was confirmed that this borehole contains a very low volume of water and that the datalogger in DBH04 is therefore likely to be recording the depth of the bottom of the borehole. This resulted in only one target in Layer 4 (DBH05) remaining.

15H.3.8 Outside the BDAW and BDAE (for which there are no available up to date calibration target data) the groundwater heads broadly match (within a few metres) expected groundwater levels. This includes areas such as the neighbouring Hinkley Point A and B power stations and the groundwater levels in the south east of the model towards Wick Moor and Holford Stream. However, it is difficult to be certain about the calibration expectations for these areas due to a lack of data.

15H.3.9 The calibrated steady state model mass balance is very good with an error of less than 0.02%.

15H.3.10 The calibrated parameters in **Table 15H.3** were used as the basis for the two pumping test calibrations detailed below. It should be noted that the Kx value for layer 3 at 4.41m/d (**Table 15H.2**) is considerably higher than measured values of permeability from packer tests in the Lilstock, but is considered to represent not only the Lilstock Formation but also the effect of higher permeability in the Planorbis Beds at the base of the Blue Lias (i.e. just above the junction between the base of Layer 2 and top of Layer 3).

Table 15H.3: Calibrated Steady State Parameters

	Layer 1 permeability (m/d)		Layer 3 permeability (m/d)		Zone 2 Recharge (m/d)	Zone 2 Recharge (m/a)	Sum of Squared Residuals
	Kx	Ky	Kx	Ky			
Default parameters	0.43	0.22	0.43	0.2	0.0007	0.256	489
Final calibrated values	0.19	0.095	4.41	2.21	0.00075	0.272	58

15H.4 Pumping Test Calibrations

15H.4.1 The transient pumping test calibrations were based on the above steady state calibration and aimed to replicate the maximum drawdowns of the two pumping tests by primarily varying the storage and specific yield parameters in the model. It was intended that the calibrated permeability parameters derived during the steady state calibration would only be modified if a reasonable calibration using storage and specific yield could not be achieved. Both pumping test models were run for the same duration as the related field test, as described below.

15H.4.2 Both pumping tests were designed by EDF and undertaken using a similar cruciform pattern of monitoring wells (**Figure 15.H.10** and **Figure 15.H.11**). Due to the proximity of the closest monitoring boreholes to the pumping borehole and the resolution of the model, it was decided to use only the drawdown curves for the most distant wells from each test. The most distant wells are also the most representative of the bulk aquifer properties.

15H.4.3 Groundwater Vistas requires specific storage to be entered into the model, not the storage coefficient. Specific storage was calculated by dividing the storage coefficient by the average layer thickness (27.95m, 34m, 5m, 9.24 and 38.18m for Layers 1 to 5 respectively) for each layer. This resulted in specific storage values of 3.6E-06, 2.9E-06, 2E-05, 1.1E-06 and 2.6E-07 for Layers 1 to 5 respectively. The specific storage value of 3.6E-06 for Layer 1 was addressed during the two pumping test calibrations as detailed below.

a) 2008 Pumping Test Transient Calibration

15H.4.4 Following steady state calibration, the model was calibrated against pumping test data supplied by EDF as collected during the on-shore hydrogeological testing in December 2008. The pumping well (PW) was pumped for a continuous 48 hours at a rate of 22.5m^3/h for the first 36 hours, followed by a reduced rate of 18m^3/h to reduce drawdown and avoid damaging the pump. Drawdown curves were supplied for twelve monitoring wells (PZ1 – PZ12) surrounding the pumping well, from which the approximate maximum drawdown in each was estimated.

15H.4.5 Two of the further monitoring wells were selected against which to calibrate the model (maximum drawdown) to represent the drawdown from the pumping well in both the north-south and east-west directions. The monitoring wells chosen were PZ1 to the west and PZ6 which is to the north of the PW pumping well (**Figure 15.H.10**). The maximum drawdowns (targets) were estimated at PZ1 (4.5m) and PZ6 (5.2m). It is suggested from these drawdown observations that this pumping test did not show any horizontal anisotropy in the aquifer (although analysis of the retest of this pumping well in August 2010 did show an anisotropy of around 1.3:1 Ky:Kx). As the initial parameters for the model, and the steady state calibration were conducted on the basis of a 2:1 Ky:Kx anisotropy, it is clearly not possible for the model to reproduce the PZ1 and PZ6 drawdowns from this pumping test without removing the anisotropy from the permeabilities in the model.

15H.4.6 It should also be noted that because of the short duration of the test relative to the time step of the model, it was not possible to reproduce time-series drawdowns in the piezometers; hence calibration has much greater relevance to the permeability than the storage properties.

15H.4.7 **Table 15H.4** shows the results of the 2008 pumping test calibration. Iteration 1 shows that the model is insensitive to changes in specific yield in Layer 1. Iterations 2-11 show that the model is, however, sensitive to specific storage in Layer 1 with a reduction of approximately one order of magnitude required in order to reduce the calculated drawdown in the model towards the target drawdowns. The half an order of magnitude difference in specific storage between iterations 10 and 11 showed no discernable difference in the drawdowns calculated in the model which suggests that the value of 1.0E-7 for Layer 1 specific storage is towards the lower bound of this parameter (using steady state calibrated permeabilities).

15H.4.8 Up to iteration 10/11, it is clear that the drawdown for PZ6 to the north of the PW pumping well could not be achieved, and that a significant residual drawdown remains present in the model. The calculated drawdown of PZ1 To the west is significantly better at within 20cm.

15H.4.9 To attempt to address this difference, iterations 12 to 14 show the results following variations in Ky. The model failed to converge with reduced values of Ky (most probably due to a lack of water in the vicinity of the pumping well). This was attempted to be addressed in iteration 15 by raising specific storage. However the iteration 15 model also failed to converge.

Table 15H.4: 2008 Pumping Test Model Calibration for PZ1 and PZ6.

	Layer 1						W	N	Sum of Squared Residuals	
Iteration	Kx (E-W) m/d	Ky (N-S) m/d	Kz m/d	Sy	Ss (S/m)		PZ1	PZ6		Comments
						Targets	4.5	5.2	PZ1 & PZ6

NOT PROTECTIVELY MARKED

b) 2010 Pumping Test Transient Calibration

15H.4.10 Calibration was also performed against the constant rate phase of the second pumping test performed in 2010. The pumping well PW2-1 (**Figure 15.H.11**) was pumped at a rate of 1.52l/s for 4 days followed by a period of recovery. Based on the results and conclusions from the assessment of the first pumping test (see above) four of the monitoring wells were chosen against which to calibration of the model response was undertaken. The monitoring wells chosen were PZ2-6, PZ2-5, PZ2-1 and PZ2-12. These four wells represent the furthest monitoring wells from the pumping well in all four directions. This allows the largest aquifer volume response to be assessed. As per the previous pumping test the monitoring wells closest to the pumping well were not included due to their high response versus model discretisation.

15H.4.11 The 2010 pump test was undertaken in July 2010 with the constant rate test lasting 4 days precisely. The desired pumping rate was 1.5l/s (130m^3/day) with records taken manually using totalising and electromagnetic flow meters. The drawdown from the pumping test was measured in a cross configuration of observation boreholes, which extended north to south and east to west. These boreholes were situated at distances of between 3m and 50m from the pumping well. The model cell resolution in the vicinity of the pumping test was 10m in both the north – south and east – west directions.

15H.4.12 **Figure 15.H.9** shows the results from the 2010 pumping test. This plot shows the drawdown observed at the end of the test in addition to the end of test observed groundwater level and borehole name. **Figure 15.H.9** shows that the peak observed drawdown during the pumping test are greater along the east-west transect compared to the north-south transect. In the east-west direction the observed drawdowns are 6.0m and 6.1m in the most easterly and westerly observation boreholes respectively. In the north-south direction, the drawdowns at the same distance from the pumping well are 3.9m and 3.5m respectively.

15H.4.13 It should be noted that this pumping test was undertaken during July 2010 during the summer dry period observed in borehole hydrographs. As the steady state calibration was undertaken based on winter groundwater levels (January 2010), the steady state model was re-calibrated using a lower zone 2 recharge (173mm/a) to match the July heads. If this correction were not applied, the model would require far more pumping to match the July 2010 pumping test observed drawdowns.

15H.4.14 **Table 15H.4** shows the results of the 2008 pumping test calibration. All of the observation and abstraction boreholes are completed in the Blue Lias (Layer 1) so fitting the observed drawdowns focused on changing the hydraulic parameters in Layer 1. In the first set of iterations the Layer 1 specific yield was varied to try and simulate the observed drawdowns (**Table 15H.4**, iterations 1-6). During the later iterations (7-11), Kx and Ky were varied to try and improve the drawdowns based on the anisotropy observed in the test and present in the default permeability data.

15H.4.15 The initial model iterations (1-6) resulted in modelled drawdowns that were too small compared to the observed data. The specific yield was reduced within these iterations, however this resulted in the model drying up with these lower specific yield rates. The specific yield in iteration 6 (0.007) was the lowest specific yield where the pumping well in the model did not run dry, but at this specific yield, all the modelled drawdowns were too low.

15H.4.16 It was concluded that iteration 9 represents the best combination of parameters to calibrate the model to observed 2010 pumping test drawdowns. The layer 1 Kx, Ky, Sy and Ss parameters from iteration 9 (**Table 15H.5**) were entered into the full transient model as the default parameters for Layer 1. Although iteration 10 does show slightly better residuals heads, the change to the horizontal anisotropy ratio was deemed to be less realistic than for iteration 9.

15H.4.17 Two pumping tests (at PW and PW2-1), both located in important areas of the site, have provided valuable insights into the behaviour of the aquifer, in particular in demonstrating the complex manner in which water levels would evolve during long term pumping. Model calibration has attempted to use this information explicitly, as well as drawing on them as a source of knowledge about the aquifer. The explicit use of this information is particularly important at Hinkley Point C because there are very few measured flows to guide the calibration. However, because of the necessarily coarse grid and time step used in groundwater flow models, it cannot be expected to fully reproduce the detailed responses observed in the pumping tests. Nevertheless, this part of the calibration has shown that the permeability parameters derived from field testing and the steady state calibration appear reasonable, and also provide an indication that the storage parameters, which are assessed in more detail in the next section, are credible. In addition, the horizontal anisotropy observed at PW2-1 has been reproduced in the model.

Table 15H.5: 2010 Pumping Test Calibration Results

Iteration	Layer 1 kx (m/d)	Layer 1 ky (m/d)	Layer 1 Specific Yield (Sy)	Layer 1 Specific Storage (Ss)	PZ2-1 (East)	PZ2-5 (West)	PZ2-6 (North)	PZ2-12 (South)	Comment
					Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m) Residual (m)	
				Observed drawdown (m) >	6.00	6.10	3.93	3.52	
Default	0.19	0.095	0.03	3.60E-06	1.7 / 4.31	1.6 / 4.5	1.1 / 2.83	0.6 / 2.92	Modelled drawdowns too low in all four boreholes
1	0.19	0.095	0.01	3.60E-06	3.5 / 2.51	3.3 / 2.8	2.4 / 1.53	1.5 / 2.02	As default, but with reduced Specific Yield. Increased drawdown in all layers which is an improved model fit
2	0.19	0.095	0.03	1.00E-06	1.7 / 4.31	1.6 / 4.5	1.1 / 2.83	0.6 / 2.92	As default, but with reduced Specific Storage. No difference (2 .d.p.) from default results. This suggests no sensitivity to Specific Storage at the monitoring borehole locations
3	0.19	0.095	0.005	3.60E-06	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	As default, but with the Specific Yield reduced more than in iteration 1. The fit compared to observed drawdowns is close. Pumping well runs dry during the final pumping period.
4	0.19	0.095	0.002	3.60E-06	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	As default, but with the Specific Yield further reduced more than in iteration 3. This value is consistent with the storage figure in the Hinkley C pump

Iteration	Layer 1 kx (m/d)	Layer 1 ky (m/d)	Layer 1 Specific Yield (Sy)	Layer 1 Specific Storage (Ss)	PZ2-1 (East)	PZ2-5 (West)	PZ2-6 (North)	PZ2-12 (South)	Comment
					Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m) Residual (m)	
									test analysis. Pumping well runs dry in this simulation after one time step and the pumping stops.
5	0.19	0.095	0.005	3.60E-06	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	N/A as pumping well dries out	As iteration 3, but re-wetting turned enabled. Model takes far longer to converge. The pumping cell still runs dry.
6	0.19	0.095	0.007	3.60E-06	4.2 / 1.81	3.9 / 2.2	3.1 / 0.83	2 / 1.52	As default, but reduced Sy below iteration 1. This iteration does not dry out at the pumping well. This is as low as the pumping can go with current hydraulic conductivity.
7	0.38	0.19	0.0035	3.60E-06	3.8 / 2.21	3.6 / 2.5	3.2 / 0.73	2.4 / 1.12	As iteration 6, but increased Kx and Ky, and reduced Sy. This run does not dry out at the pumping well. Drawdowns slightly less than iteration 6
8	0.38	0.19	0.002	3.60E-06	4.5 / 1.51	4.3 / 1.8	3.9 / 0.03	3.1 / 0.42	As iteration 7, but with reduced storage. The pumping well in this iteration did not dry out. Improved fits on drawdowns, especially along the N-S transect
9	0.38	0.19	0.001	3.60E-06	5.5 / 0.51	5.3 / 0.8	4.8 / -0.87	4 / -0.48	As iteration 8, but with reduced storage. The pump in this run did not go dry. The fit on the N-S transect has got worse, and the E-W

Iteration	Layer 1 kx (m/d)	Layer 1 ky (m/d)	Layer 1 Specific Yield (Sy)	Layer 1 Specific Storage (Ss)	PZ2-1 (East)	PZ2-5 (West)	PZ2-6 (North)	PZ2-12 (South)	Comment
					Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m)/ Residual (m)	Modelled Drawdown (m) Residual (m)	
									transect has improved compared to observed drawdowns.
10	0.53	0.134	0.001	3.60E-06	5.8 / 0.21	5.5 / 0.6	4.1 / -0.17	3.3 / 0.22	As iteration 9. Increased anisotrophy in layer 1 horizontal conductivity to try and extend the cone of depression to better match the larger drawdowns E-W compared to N-S.
11	0.7	0.1	0.001	3.60E-06	5.9 / 0.11	5.6 / 0.5	3.7 / 0.23	2.8 / 0.72	As iteration 10. Further increases to the amount of anisotrophy in layer 1 horizontal conductivity. Improved matching of observed drawdowns on some boreholes (along the E-W transect), the match to observed drawdowns on the N-S transect has become slightly worse

c) Full Transient Model Calibration

15H.4.18 The final calibration was carried out using a transient model designed to represent a two year period of rainfall calculated on a monthly basis (**Table 15H.6**). The two-year period was chosen to allow the model to stabilise during the first year prior to a comparison against observed hydrographs during the second year.

15H.4.19 The 24 months in the model were aggregated into 24 stress periods (SPs) to represent each month of the year. This resulted in 25 stress periods overall (SP1 remaining steady state to provide a stable numerical basis for the starting model, as recommended by Groundwater Vistas software documentation). The 24 months of recharge distribution is based on the conceptual annual recharge model described in **Chapter 15** and represents an average annual rainfall appropriate to the Hinkley region and is not a Hinkley Point C specific rainfall pattern. The calibration results (hydrographs) presented below therefore do not exactly match the observed data, but aim to match the amplitude of the winter peak and summer fall in heads. This is an appropriate calibration methodology as future rainfall patterns are unknown and therefore the average recharge distribution is considered more appropriate.

15H.4.20 Boreholes CBH24, CBH33 and DBH10 were selected for the purposes of transient calibration to provide a south-north cross section of heads through the Built Development Area. The field hydrographs for these boreholes show high water levels in the winter months (November – February) and a long recession through the summer and early autumn (see **Figure 15.H.12**). To compare with simulated model heads from the average annual recharge distribution, and to account for the variable seasonality of groundwater level minima and maxima, the hydrographs in **Figure 15.H.12** where shifted forwards 91 days in time to allow the curves to be matched.

15H.4.21 Several transient model iterations and the final calibrated values are summarised in **Table 15H.7**. The aim of the iterations was to produce an average annual model response of the same magnitude as the winter/summer head changes shown in observed data. During the calibration process and further consideration of the conceptual system Layers 2 and 3 were changed to convertible (confined/unconfined) layer type status.

15H.4.22 **Figure 15.H.13** to **Figure 15.H.15** show the calculated model hydrographs for the calibrated transient model for the target boreholes CBH24, DBH10 and CBH33 respectively. The figures show that a good average transient calibration has been achieved for Layer 1 through the development area from south to north.

15H.4.23 **Figure 15.H.16** shows the transient calibration contours for Layer 1 in the second January of the two year simulation period (representative of a wet time of year). **Figure 15.H.17** shows the Layer 1 transient calibration contours from the final October of the two year simulation (representative of a dry time of year, before the late autumn/winter increase in recharge). The figures show a 2-4m drop in groundwater head between the two periods which is a good match to changes in observed groundwater levels.

15H.4.24 The overall mass balance for the calibrated full transient model is very good at less than 0.4% error.

APPENDIX 15I: CONTAMINANT TRANSPORT ASSESSMENT

[This page is intentionally left blank]

APPENDIX 15I: CONTAMINANT TRANSPORT ASSESSMENT

15I.1 Introduction

15I.1.1 This appendix details a contaminant transport assessment regarding the potential for contaminants from the Hinkley Point A (HPA) site to cause impacts to the Hinkley Point C (HPC) site during the period of construction dewatering.

15I.1.2 This approach involved a tiered assessment utilising both contaminant and source screening, and modelling using GoldSim as discussed below.

15I.2 Scope and Methodology

a) Introduction

15I.2.2 The tiered assessment involved the successive screening (and elimination) of potential contaminant sources from an initial schedule, so that detailed assessment was focused on the most relevant contaminants and sources that remain (i.e. those that are not excluded at the previous tier).

For this study the following tiers have been employed (**Figure 15I.1**):

- Tier 1 – contaminant and source screening; and
- Tier 2 – modelling of those sources not eliminated at Tier 1.

b) Assumptions

15I.2.3 This section details the general assumptions made across this study both at Tier 1 and 2, and highlights the conservative approach adopted through many aspects of the modelling process. The following conservative assumptions should be taken into account when considering any marginal failures of the Tiered Assessment process, detailed later in this section:

- Groundwater contaminants are present in the shallow Lower (Blue) Lias aquifer present beneath the HPA site.
- Unsaturated zone transport was ignored as a conservative assumption. Contamination present in perched water above the main groundwater level would have a significantly faster travel time to receptors than through the unsaturated zone. Where it is not clear if reported contaminant data is in the unsaturated zone or aquifer, it is conservatively assumed to be present in the saturated zone.
- A direct pathway to the HPC new build site is present once dewatering begins. This is a conservative assumption as the pathlines in **Figure 15I.2** suggest that the groundwater pathway would actually be curved (i.e. longer).
- It is assumed that advection dominates contaminant transport on the Hinkley Point sites and diffusion is not considered here. Except where groundwater velocities are very low, molecular diffusion is commonly disregarded, especially at the site scale.
- It is assumed that all contamination is fully dissolved and no free-phase hydrocarbon product is present.

- Where site specific data are not available, literature values and professional judgement were applied.
- Source term concentrations lacking specific values (as shown **Figure 15I.3** to **Figure 15I.6**) were assumed to be at top end of their respective concentration ranges.
- It was assumed that all beta activity is due to Sr-90. In reality it is likely that some beta activity is due to naturally occurring K-40 etc. This assumption provides an overestimate of Sr-90 concentrations. Some beta may also be due to Cs-137 which is more highly retarded than Sr-90. Assuming beta activities are 100% Sr-90 is a conservative assumption for the purposes of retardation and travel time.
- Biodegradation and retardation occurs. The model is run with biodegradation (decay) both on and off. Appropriate literature values are used for biodegradation rates for naphthalene.
- Sources of identical contaminants are modelled as separate sources but together in the same model and results reported as total (combined) concentrations.
- Background concentrations are assumed to be zero.
- Dewatering duration is assumed in the model to be five years, adding a one-year margin to the design four years.
- In the cases where TPH and Diesel Range Organics (DRO) contamination has been identified, for the purposes of the model this has been assumed to be naphthalene (a more mobile hydrocarbon).

15I.3 Tiered Assessment Process

15I.3.1 A tiered assessment process was used which is regarded as best practice in the UK by the Environment Agency (EA) Model Procedures for the Management of Contaminated Land guidance (Ref. 15I.1). The basis of tiered assessments is to apply successive or more complex tests to selected contaminants with a view to eliminating insignificant contaminants from the need for further assessment. This is efficient (since it avoids unnecessary effort devoted to contaminants that can be screened out early on) and also provides an objective indication of the contaminants that are potentially significant and require further assessment.

15I.3.2 The assessment is considered complete for any given contaminant and tier level once it has been demonstrated that the contaminant has passed (i.e. has not been shown to exceed screening levels) the given tier of assessment. Only if a contaminant assessment fails at a given tier level is it necessary to proceed to the next tier. The EA tiered assessment approach is therefore designed such that it may not necessarily have to be completed in its entirety.

15I.3.3 In Tier 1, two screening criteria are used to interrogate the data. The first screens out sources which lie outside (i.e. to the north and east) of the dewatering-induced flow divide line across the HPA site identified from the groundwater flow model (**Figure 15I.7**) which id detailed in **Chapter 15** of this volume. The second screens out sources which have groundwater contaminants already lower than the compliance screening values. Only contaminant sources which cannot be excluded by either of these criteria are considered further in the Tier 2 assessment.

a) Tier 1 – Contaminant Screening

15I.3.4 Groundwater contamination on the HPA site was screened against UK drinking water standards (DWS), World Health Organization (WHO) guideline values and Environmental Quality Standards (EQS) in order of decreasing preference.

15I.3.5 Certain contaminants with documented low solubility and/or low mobility were also screened out qualitatively, e.g. PCBs.

15I.3.6 Only contaminants failing the Tier 1 assessment were assessed at Tier 2.

15I.4 Contaminant Screening Criteria

15I.4.1 The following contaminant screening criteria were derived for this assessment.

- UK DWS:
  - H-3: 100 Bq/l (2.79E-10mg/l)
  - Hg: 0.001mg/l
- WHO Guideline Values:
  - Sr-90: 10 Bq/l (1.95E-9mg/l)
- EQS (freshwater):
  - Naphthalene: 0.01mg/l
  - Speciated PAHs (naphthalene): 2.4E-3mg/l
  - Hg: 5.0E-5mg/l

a) Tier 1 – Source Screening

15I.4.2 Source screening was also undertaken on the basis of the likely capture zone from the proposed dewatering on the HPC site (**Figure 15I.7**). Sources outside this capture zone were screened from further assessment as they are not likely to be drawn towards the HPC site during construction dewatering.

b) Tier 2 – Quantitative Assessment (GoldSim Modelling)

15I.4.3 Contaminants failing the Tier 1 screening process were taken forward for consideration at Tier 2 which in some cases included modelling using GoldSim where necessary (see below). Contaminants were modelled over two distances:

- from source to the HPA/C site boundary (**Figure 15I.8** and **Figure 15I.9**); and
- from source to the closest engineering dewatering location, determined to be the north west corner of the proposed main nuclear island (**Figure 15I.10** and **Figure 15I.11**).

15I.4.4 Predicted concentrations of contaminants were calculated at both compliance locations (site boundary and dewatering location) and compared to DWS and EQS values in order to determine their significance if mobilised onto the HPC site.

15I.4.5 For the deterministic (best estimate) simulation, maximum concentrations from four modelled receptors were compared to screening values.

15I.4.6 To address potential parameter uncertainty and variability the, UK best practice requires a set of stochastic (Monte Carlo) models to determine whether the deterministic models may have underestimated receptor concentrations.

15I.4.7 For the Monte Carlo simulations, 95th percentile values were compared to screening values. Two sets of Monte Carlo assessments were conducted. Firstly, a set of Monte Carlo assessments were conducted where one single parameter was varied in each case. A second, more complex set of Monte Carlo assessments were also conducted where several (non-mutually exclusive) parameters were varied together.

15I.5 Tier 1 Assessment

a) Contaminant Screening

15I.5.2 For the Tier 1 assessment, the following groundwater contaminants summarised as of significance by SERCO (2010) (Ref. 15I.2) were assessed (**Figure 15I.3** to **Figure 15I.6**):

- Sr-90. Beta emitter thought to represent about 50% of the total beta activity on the HPA site (**Figure 15I.3**).
- H-3 (**Figure 15I.4**). Two sources of H-3 (tritium) higher than DWS are included in the assessment. Other sources, some of which are closer to the site boundary are not included as they are lower than DWS at source. One source at 148Bq/l exists just to the east of the flow divide in **Figure 15I.4**. This (148Bq/l) is a small failure of the H-3 DWS (approximately one order of magnitude less than the two sources included) and dilution will reduce this concentration to below the DWS over the distance to the site boundary. Therefore it was not included.
- Diesel range organics (DRO) and heavier mineral oil organics (compounds from C21-C38 range). According to recent EA guidance (Table 5.1 in Consim Manual Release 2, Golder Associates (Ref.15I.3)) hydrocarbons in the range C18-C34 (DRO) are not considered mobile. It is assumed here that naphthalene is a suitable analogue for the lighter total petroleum hydrocarbon (TPH) fractions potentially present on the HPA site in the absence of speciated data in SERCO (2010) (Ref. 15I.2). No contaminants in the C21-C38 range were modelled here as these are not considered mobile.
- Naphthalene. SERCO (Ref. 15I.2) refers to potential sources of TPH which are not speciated. As TPH covers a wider range of organic compounds including lighter fractions than DRO (above), the assessment here has taken several TPH sources (**Figure 15I.5**) and conservatively assumed that they are composed entirely of naphthalene. Naphthalene is a conservative assumption as it is too heavy to volatilise quickly and is relatively mobile compared to other potential TPH components.
- Mercury (Hg). Slightly elevated mercury was measured in borehole G10 (**Figure 15I.6**) in 2004 at 3.9µg/l (**Figure 15I.6**). This borehole was not re-sampled during the 2009 sampling reported in (SERCO 2010 (Ref. 15I.2)). Borehole G10 is located close to the HPA site boundary in the direction of groundwater flow under dewatering conditions. For both of these conservative reasons this potential Hg contamination was included in the Tier 1 assessment.
- Other metallic compounds. (SERCO 2010 (Ref. 15I.2)) lists a small number of other metallic compounds that are occasionally present above DWS. However, these were thought to be due to sulphidic mineralisation and leaching of the Lower (Blue) Lias and are not man-made sources of contamination (SERCO 2010

(Ref. 15I.2)). No specific sources of metallic contamination are identified and therefore no other metals were identified for the Tier 1 assessment.

- PCBs. There is only anecdotal evidence that PCBs may be present on the HPA site in (SERCO 2010 (Ref. 15I.2)). Due to their immiscible and highly retarded nature, PCBs were not included in this assessment. PCBs are not widely regarded as mobile groundwater contaminants.

15I.5.3 Where specific source term concentrations were not specified in (SERCO 2010 (Ref. 15I.2)) the upper value of the range (see **Figure 15I.3** to **Figure 15I.6**) was assumed as a conservative assumption.

b) Source Screening

15I.5.4 **Figure 15I.7** shows the effects of the proposed HPC dewatering drawdown on the HPA site. The zone of influence only extends part way across the HPA site. Hinkley Point B (HPB) is located further to the East and is therefore uninfluenced by the HPC dewatering. HPB was therefore not considered further in this assessment.

15I.5.5 On **Figure 15I.7** a green line is shown which approximately marks a flow divide under dewatering conditions based on the MODFLOW pathlines shown in red. Contaminants to the south and west of this line are likely to be drawn towards the HPC development site under dewatering conditions. Contaminants to the north and east of the green line are likely to flow towards the Bristol Channel as under baseline conditions and will not impact the HPC site.

15I.5.6 The precise location of this flow divide is unknown and the green line in **Figure 15I.7** represents an approximate location. As the results of this assessment will show, contaminants present in groundwater close to this line are clearly not of concern, hence only the approximate location of this flow divide is required.

15I.5.7 **Figure 15I.3** to **Figure 15I.6**, which are based on data from (SERCO 2010 (Ref. 15I.2)) were primarily used to specify the number of source term locations on the HPA site for the Tier 2 assessment (i.e. those sources deemed to be significant by SERCO (Ref. 15I.2)) with more recent data from Golder (Ref. 15I.4, Ref. 15I.5) also included.

i. H-3 Contamination (G35)

15I.5.8 In July 2009, a H-3 concentration of 438Bq/l was recorded in borehole G35. In February 2010 this had reduced to 89.5Bq/l and therefore below the UK DWS screening value. This source does not require further assessment as it is below the Tier 1 screening value at a concentration that would be fit for human consumption.

ii. H-3 Contamination (G42A)

15I.5.9 In April 2010 a H-3 concentration of 295Bq/l was recorded in borehole G42A. By September/October 2010 this had reduced to 36.2Bq/l (below UK DWS screening level) and does not require further assessment as it is below the Tier 1 screening value at a concentration that would be fit for human consumption.

iii. H-3 Contamination in Borehole (G44)

15I.5.10 In May 2001 a H-3 concentration of 325Bq/l was recorded in borehole G44. In September/October 2010 this had reduced to 39.7Bq/l and hence below the UK DWS screening value. This does not require further assessment as it is below the Tier 1 screening value at a concentration that would be fit for human consumption.

iv. Hydrocarbon Contamination (G2B)

15I.5.11 Borehole G2B is further to the east of the HPA site than the groundwater flow divide (**Figure 15I.7**). The direct distance from G2B to the HPC dewatering zone is over 670m. **Figure 15I.12** shows a set of particle traces in the MODFLOW model released along the same northing as borehole G2B. The capture zone is based on a set of unretarded particles inserted into the MODFLOW groundwater model. Unretarded particles to the east of this line will not reach the dewatering location over the five year dewatering period.

15I.5.12 It is therefore highly unlikely that retarded hydrocarbon contamination present in groundwater in borehole G2B (outside of the capture zone) will migrate onto the HPC site during the five year dewatering period and hence this source does not require assessment.

v. Hydrocarbon (Free Phase) Contamination (G40)

15I.5.13 Borehole G40 is also located further to the east of the HPA site than the groundwater flow divide (**Figure 15I.7**). It is highly unlikely conceptually that free phase hydrocarbons can migrate onto the HPC site over a five year period from this location, because free phase contamination is not dissolved and is highly immobile.

15I.5.14 The free phase hydrocarbon contamination in G40 therefore does not require assessment.

15I.6 Tier 2 Assessment (GoldSim Model)

15I.6.1 From the Tier 1 assessment, the following contaminant types require further consideration:

- Tritium (H-3);
- Strontium-90 (Sr-90);
- Naphthalene; and
- Mercury (Hg).

15I.6.2 Of these contaminants, H-3 is by far the most mobile as it is by nature unretarded. An assessment of H-3 was undertaken at Tier 2 to determine whether this most mobile contaminant presents a significant risk to the HPC site or the dewatering location. It was decided that if H-3 presented no significant risk then the other contaminants failing Tier 1 (which are retarded to some degree) would also not present a significant risk, so long as they are not present on the HPA site at a location closer to the HPC site. **Figure 15I.5** and **Figure 15I.6** show that only source 7 containing Hg and hydrocarbons (naphthalene; but not Sr-90) is located very close to the HPA/C site boundary. This source was therefore considered at Tier 2.

a) Generic Parameters

15I.6.3 Site parameters for the deterministic (best estimate) Tier 2 assessment using GoldSim are presented below and in **Table 15I.1**.

- Only groundwater source term concentrations present in the aquifer were modelled (this assessment does not consider the overlying unsaturated zone, a conservative approach).
- Biodegradation/radioactive decay were included.
- All sources with the same contaminants were modelled collectively (total concentrations at receptors are reported in the results below).
- Longitudinal and lateral dispersivity were set to 1/10th and 1/30th of the source to receptor path length respectively and were not varied stochastically. This assumption was taken to avoid excessive or unrealistic lateral dispersion.

15I.6.4 Site Parameters – Monte Carlo (only where different from deterministic model parameters in **Table 15I.1**). GoldSim models with only individual stochastic parameters:

- 1000 model iterations.
- All stochastic parameters were entered as uniform distributions.

15I.6.5 See **Table 15I.1** for parameter ranges. Model sensitivity to each parameter is assessed separately.

15I.6.6 Site Parameters – Monte Carlo. Combined parameter models (models with combined but unrelated parameters). Refer to **Table 15I.1** for parameter ranges where they are not quoted here:

- Partition coefficient for retarded contaminants (Sr-90, naphthalene and Hg) +/- 1 order of magnitude compared to deterministic values in **Table 15I.5**, and naphthalene biodegradation rate: 0 – 1 years.
- Porosity and hydraulic gradient.
- Partition coefficients (+/- 1 order of magnitude), naphthalene degradation rate (0 - 1 years), porosity and hydraulic gradient.

15I.7 GoldSim Model Setup

15I.7.1 The GoldSim models were run for a five year dewatering period giving an additional one-year conservative margin to the design dewatering period of four years.

15I.7.2 **Table 15I.1** details the hydrogeological parameters used in the models.

Table 15I.1: Site Parameters (GoldSim).

Parameter	Units	Best Estimate (deterministic)	Best Estimate Justification	Range (Monte Carlo)	Monte Carlo Justification
Source areas	m^2	1	Simple assumption. Model insensitive to source area.	n/a	Unit area, variation not required.
Dry bulk density	g/cm^3	1.8	Conservative estimate based on brief qualitative assessment of raw SSL data. EDF interpretation indicates 2.1-2.6 (best estimate 2.37) which would increase retardation for all contaminants (except H-3 for which it is irrelevant).	1.5-2.2	Wide range of values to represent potential geology present at HPA/HPC.
Porosity	-	0.02	Expert opinion based on site specific data (0.03 upper bound for limestone effective fracture porosity, 0.02 for mudstone). A range of values to be simulated in Monte Carlo assessments.	0.01-0.05	Range of potential porosities from 1-5% to represent potential fracture flow porosity variability.
Aquifer thickness	m	35	Estimated from conceptual model and MODFLOW model. Saturated thickness of Lower (Blue) Lias aquifer.	10-50	Lower bound thickness of 10m represents flow through Lower (Blue) Lias limestone bands only. Upper bound thickness of 50m to represent large scale matrix flow through entire thickness of Lower (Blue) Lias aquifer. GoldSim model not sensitive to this parameter.
Hydraulic conductivity	m/s	4.4E-6	Average value taken from calibrated MODFLOW model in [2].	9E-7 – 5.1E-5	One order of magnitude range selected to represent a significant variation in the calibrated MODFLOW value used in the deterministic assessment. Monte Carlo values represent the range 0.1-1m/d.
Hydraulic gradient	-	0.019	Calculated as average of two hydraulic gradients: from centre of HPA site to EDF site boundary and centre of HPA site to closest dewatering location based on MODFLOW groundwater contours	0.01-0.03	A significant range of hydraulic gradients particularly towards the steeper/conservative end of the range (0.03). Higher hydraulic gradients coupled with very low porosities will generate a significantly higher groundwater velocity than is expected to occur under dewatering conditions.
Groundwater flow direction	Degrees	270	Direct path to receptors, conservative assumption - curved/longer path predicted in	n/a	GoldSim is a one dimensional model, flow direction is therefore not relevant.

Parameter	Units	Best Estimate (deterministic)	Best Estimate Justification	Range (Monte Carlo)	Monte Carlo Justification
			MODFLOW model		
Longitudinal dispersivity	m	1/10th path length	Calculated following direct advice from software vendor. Should not be varied stochastically.	n/a	Model sensitive to this parameter. Higher values lead to extremely large lateral dispersion at source which is not appropriate. Advice received from software developer.
Lateral dispersivity	m	1/30th path length	Calculated following direct advice from software vendor. Should not be varied stochastically.	n/a	Model sensitive to this parameter. Higher values lead to extremely large lateral dispersion at source which is not appropriate. Advice received from software developer.
Source term infiltration	mm/yr	25	Based on conceptual and MODLFOW models.	-	GoldSim assessment results are not sensitive to this parameter.

15I.8 H-3 Assessment

15I.8.1 H-3 was modelled with a half-life of 12.33 years, a partition coefficient of 0ml/g (unretarded) and unlimited solubility.

Recent monitoring data for H-3 (2009/2010) indicate that:

- Measured H-3 concentrations on the HPA site have declined since 2004/5. For example, the concentration in borehole G7 has dropped from 1000 to 180 Bq/l.
- The highest recording in 2004/5 was in borehole A6 which has since been infilled and which therefore cannot provide further data.
- Due to uncertainty regarding the H-3 source, it cannot be confirmed whether the centre of the plume has been intercepted.
- The boreholes on the HPA site are all shallow. The northern wells in particular may therefore miss H-3 contamination travelling northwards due to dips in the geological strata.

15I.8.2 Due to the above, it was decided to model decayed H-3 source terms from the position of the G7 and A6 boreholes as opposed to using the lower concentrations as measured on-site during 2010 (**Figure 15I.13**) as this is a conservative approach given the above conceptual uncertainties.

15I.8.3 On the basis of the 2004/5 data presented above, it was calculated that late December 2010 concentrations at G7 and A6 following radioactive decay alone would be 706 and 1349Bq/l respectively. The concentrations are fixed and do not decline with time.

15I.9 H-3 Tier 2 Results

15I.9.1 The results of the H-3 assessment are shown in **Table 15I.2** below. For the deterministic model, H-3 peaks at the site boundary at approximately five times less than the UK drinking water standard of 100Bq/l. The dewatering location being further from the sources shows an insignificant peak concentration of 6.1Bq/l. Neither result is therefore significant.

15I.9.2 Overall, the highest concentration predicted at the site boundary is from the Monte Carlo model of permeability and hydraulic gradient in combination. However, at 20.5Bq/l, the increase from the deterministic result is small, and remains approximately five times lower than the UK Drinking Water Standard for H-3. At the dewatering location, the highest result overall (7.7Bq/l) remains insignificant.

Table 15I.2: GoldSim H-3 Contaminant Transport Results

	Site Boundary (Bq/l)	Dewatering (Bq/l)
Deterministic	18.9	6.1
Monte Carlo Prediction (95th ile) Parameter Varied:		
Effective Porosity	19.6	7.0
Aquifer thickness	18.9	6.1
Hydraulic conductivity	20.4	7.7
Hydraulic gradient	19.7	6.9
Porosity & hydraulic gradient	19.9	7.2
Permeability & hydraulic gradient	20.5	7.7

15I.9.3 A final Monte Carlo assessment was also undertaken to increase the permeability in the model to account for on-site pumping test results which may show higher localised areas of permeability than is apparent from the MODFLOW calibrated model. The results of this analysis are shown in **Table 15I.3**. The results show that the model is relatively insensitive to increases in permeability and that no significant increases in H-3 concentrations were predicted.

Table 15I.3: GoldSim H-3 Sensitivity Assessment of Higher Upper Blue Lias Permeabilities

	H-3 Concentration at Receptor After 5 Years			
	Site Boundary		Dewatering	
Hydraulic conductivity (m/s)	**K=4.4E-06**	**K=2.2E-05**	**K=4.4E-06**	**K=2.2E-05**
Deterministic	18.9	20.3	6.1	7.6
Permeability (95th ile)	20.4	20.5	7.7	7.7
Permeability & gradient (95th ile)	20.5	20.2	7.7	7.4

15I.10 H-3 Tier 2 Conclusion

15I.10.1 It is concluded that significant concentrations of H-3 are unlikely to migrate onto the HPC site from HPA during construction dewatering, in the context of the current UK Drinking Water Standard of 100Bq/l. Whilst this assessment focuses on intergranular/matrix flow and transport, the potential for fast pathways through rock fractures does exist. These fractures are however unlikely to extend continuously from the H-3 sources to the dewatering location. Furthermore the Monte Carlo analyses undertaken (e.g. effective porosity and hydraulic gradient) do allow for significantly faster contaminant transport that would be characteristic of fast pathways.

15I.10.2 Modelling, using GoldSim and employing conservative assumptions, indicates that H-3 concentrations will not exceed approximately 20% of the UK DWS (100Bq/l) at the site boundary, and will be much lower at the dewatering locations.

a) Sr-90

15I.10.3 Sr-90 is not present on the HPA site at any sources closer than those included in the H-3 assessment. As Sr-90 is retarded and the unretarded H-3 results do not show any significant results, it is not necessary to consider Sr-90 at Tier 2. Sr-90 will not pose a significant risk to the HPC site or the dewatering location under dewatering conditions.

b) Hg and Naphthalene Assessment (Source 7)

15I.10.4 Following the H-3 assessment, both Hg and naphthalene (0.0039 and 0.6mg/l respectively) from Source 7 were assessed since the source is close to the site boundary. This assessment was carried out using the same hydrogeological parameters as shown above, and the specific contaminant properties shown in **Table 15I.4**.

Table 15I.4: Contaminant Parameters for Naphthalene and Hg.

Contaminant	Parameter			
	Half-life/ Biodegradation Rate (Years)	Partition Coefficient (ml/g)	Henry's Law Constant (-)	Aqueous Solubility (mg/l)
Naphthalene**	0.296***	6.44****	1.74E-2	31.0
Hg	Unlimited	145*****	-	Unlimited******

***All naphthalene values taken from Ref.15.I.6. Aerobic sandy loam data for naphthalene have been ignored as not appropriate to this geological assessment.*

****Most conservative/appropriate value from[5].*

*****Log soil organic carbon-water partitioning coefficient (Koc) of 3.11 taken from[5] at 25 degrees Celsius. Partition coefficient (Kd) calculated assuming a conservative Fraction of organic carbon (Foc) of 0.5%.*

******Kd at pH 6.8 as recommended by ConSim manual. At higher pHs, Hg is significantly more retarded therefore 145ml/g a conservative estimate.*

*******Assumed to not be solubility limited as a conservative assumption.*

c) Naphthalene and Hg Tier 2 Results and Conclusion

15I.10.5 The results of the GoldSim models for Hg show that in both the deterministic and Monte Carlo models, no Hg reaches the site boundary or dewatering location.

15I.10.6 For naphthalene, in both the deterministic and Monte Carlo models, no contamination reaches the dewatering location. At the site boundary, in the deterministic model, concentrations of naphthalene peak approximately ten orders of magnitude less than the UK drinking water standard. From the Monte Carlo models, the highest concentration at the site boundary rises to nine orders of magnitude less than the UK drinking water standard.

15I.10.7 It is therefore concluded that Hg and naphthalene do not present a significant risk to the HPC site or the dewatering location.

15I.11 Assessment of HPA Contaminant Depths

15I.11.1 In addition to the above assessment, a further assessment has been undertaken of the potential for groundwater contamination sources on HPA to reach the higher permeability Lilstock Formation, a zone also considered to include the Planorbis beds at the base of the Blue Lias Formation. This was considered to be an important conceptual uncertainty given the depths of investigations on the HPA site, as discussed below.

15I.11.2 According to the 1980s HPC site investigation (Ref. 15I.7), the Planorbis beds are calculated to be an average of 12.7m thick. The geological formations underlying HPC are shown to dip in a northwards direction according to various cross sections (cross section locations shown on **Figure 15I.10**). According to the north-south cross section E (reproduced here in **Figure 15I.11**), this dip results in the Planorbis beds reaching outcrop (beneath made ground) around the location of trial pit TP2. It is estimated that TP2 is located at approximately 320530, 145770; to the south east of the HPC drainage ditch (**Figure 15I.12**). It is hence estimated that the Planorbis outcrop would be approximately 280m south of the peak H-3 concentrations on HPA in borehole A6 (assuming that the Planorbis zone outcrops on the HPA site at the same northing). The east-west cross section B (reproduced in **Figure 15I.13**) is at a northing approximately around the locations of contaminant interest. From **Figure 15I.13** the top of the Planorbis beds are shown to be relatively flat across the formation strike, with a level around -28m AOD. The ground surface is shown at +15m AOD making the Blue Lias above the Planorbis approximately 43m thick at this northing.

15I.11.3 The Blue Lias to a depth of 40m below ground level is conceptualised to have an estimated vertical:horizontal permeability anisotropy of 1:800 as discussed in **Chapter 15** of this volume. This would make it highly unlikely that shallow contamination in the Blue Lias could penetrate several 10s of metres vertically downwards to the Planorbis beds. At depths greater than 40m below ground level, the Blue Lias is conceptualised to have lower horizontal permeability due to compression of the formation. Therefore in areas where the Blue Lias is very thick, vertical permeability across the entire formation will be lower still, even at a conceptualised anisotropy of 1:120, further reducing the likelihood of vertical contaminant migration into the Planorbis beds.

15I.11.4 The Monte Carlo hydraulic gradient range in the GoldSim modelling (**Table 15I.1**) was 0.01 to 0.03 with a deterministic value of 0.019. The Monte Carlo upper range of 0.03 is significantly higher than both deterministic values and therefore encompasses any increases in hydraulic gradient derived from more recent MODLFOW modelling. However, hydraulic gradient is only one of several parameters relevant to this discussion, and it should also be noted that the MODFLOW model Layer 1 (Upper Blue Lias) horizontal permeability has been reduced from 0.42m/d (on which the GoldSim model was based) to a final calibrated value of 0.38m/d which will in part reduce the effects of the increase in deterministic hydraulic gradient.

15I.11.5 **Table 15I.5** summarises the groundwater level and borehole information from HPA currently available. The installation depth data in **Table 15I.5** summarises the lithological descriptions, all of which correspond to Blue Lias type material. The March 2010 “Golder – base of BH” in **Table 15I.5** shows the depths of the boreholes where this is available. None of the boreholes penetrate the Blue Lias more than about 15m, leaving about 30m of additional Blue Lias below before the Planorbis beds are reached. The other columns in **Table 15I.5** show rest water levels from various data sources quoted across various timeframes. All the water levels are representative of Upper Blue Lias levels. In summary this demonstrates that the HPA contaminated land investigations were shallow and did not penetrate through the Blue Lias formation (which is known to be thicker than the HPA boreholes are deep). Therefore, on the basis of available information, all the contaminant data quoted is restricted to relatively shallow levels and lies well above the Planorbis beds. Whilst this cannot fully rule out deeper contamination, the high vertical permeability anisotropy of the Blue Lias formation (1:800) will actively prevent significant downwards contaminant migration. Where present, the deeper (compressed) Blue Lias is of even lower permeability and will act as an additional vertical migration barrier. The possibility of HPA contamination reaching the Planorbis beds is therefore assessed as very low.

15I.11.6 It is therefore concluded that the shallow contamination reported on the HPA site was suitably modelled in the GoldSim assessment reported above, including suitable conservative assumptions and Monte Carlo simulations and does not require repeating following more recent MODFLOW modelling.

15I.12 Conclusions

15I.12.1 The results for H-3 show that over an assumed 5 year dewatering period, H-3 from the HPA site is not likely to be drawn on to the HPA site or into the extracted dewatering water at a significant concentration compared to the current UK drinking water standard of 100Bq/l.

15I.12.2 Sr-90, Hg and naphthalene are all retarded contaminants and thus as such are even less likely to migrate a significant distance during the period of dewatering. However, some sources of these contaminants are closer to the HPA/C site boundary than for H-3, so some confirmatory modelling was undertaken. The results of this modelling confirmed that these contaminants are highly unlikely to present a risk to the HPC site or the dewatering location during dewatering.

15I.12.3 In summary, based on the above analysis there are no contaminants on the HPA site which present a risk to the HPC site or dewatering location under anticipated dewatering conditions.

APPENDIX 16A PHOTOGRAPHS

Plates 16.1 and 16.2: Photographs illustrating the catchment characteristics of Hinkley Point C Drainage Ditch. The top photo is taken from west of the source looking east northeast and the bottom photo is taken from directly north of the source, which is located in the hedgerow in the middle distance of the photograph.

Plates 16.3 and 16.4: Photographs of Holford Stream. The top photo is taken immediately upstream of C182 looking upstream. The bottom photo shows the downstream face of the old sluice where Holford Stream converges with West Brook.

Plates 16.5 and 16.6: Photographs of Holford Stream vegetation. The top photo is taken immediately downstream of C182. The bottom photo illustrates the dense channel and riparian vegetation that is characteristic of many of the watercourses in the area.

Plates 16.7 and 16.8: Photographs showing Bum Brook. The top photo is looking downstream at its confluence with Bailey's Brook. The bottom photo shows the aforementioned ford.

Plates 16.9 and 16.10: Photographs of Bum Brook. The top photo is looking upstream from C182. The bottom photo is looking downstream from C182.

Plates 16.11 and 16.12: Photographs of Stogursey Brook. The top photo is looking upstream from C182. The bottom photo is looking downstream from C182.

Plates 16.13 and 16.14: Photographs of East and West Brook. The top photo is of West Brook immediately downstream from the Bum Brook bifurcation. The bottom photo shows the confluence of East Brook (left of shot) with West Brook.

Plates 16.15 and 16.16: Photograph of East Brook immediately upstream of its confluence with West Brook (top photo) and riparian vegetation in West Brook.

Plates 16.17 and 16.18: Photographs of Great Arch Sluice upstream face (top photo) and outfall on the foreshore (bottom photo).

Plates 16.19 and 16.20: Great Arch Sluice Inspection chamber at low tide (top photo) and high tide (bottom photo).

Plates 16.21 and 16.22: Photographs of Rhyne East looking towards Cole Lane Sluice (top photo) and Cole Lane Sluice (bottom photo).

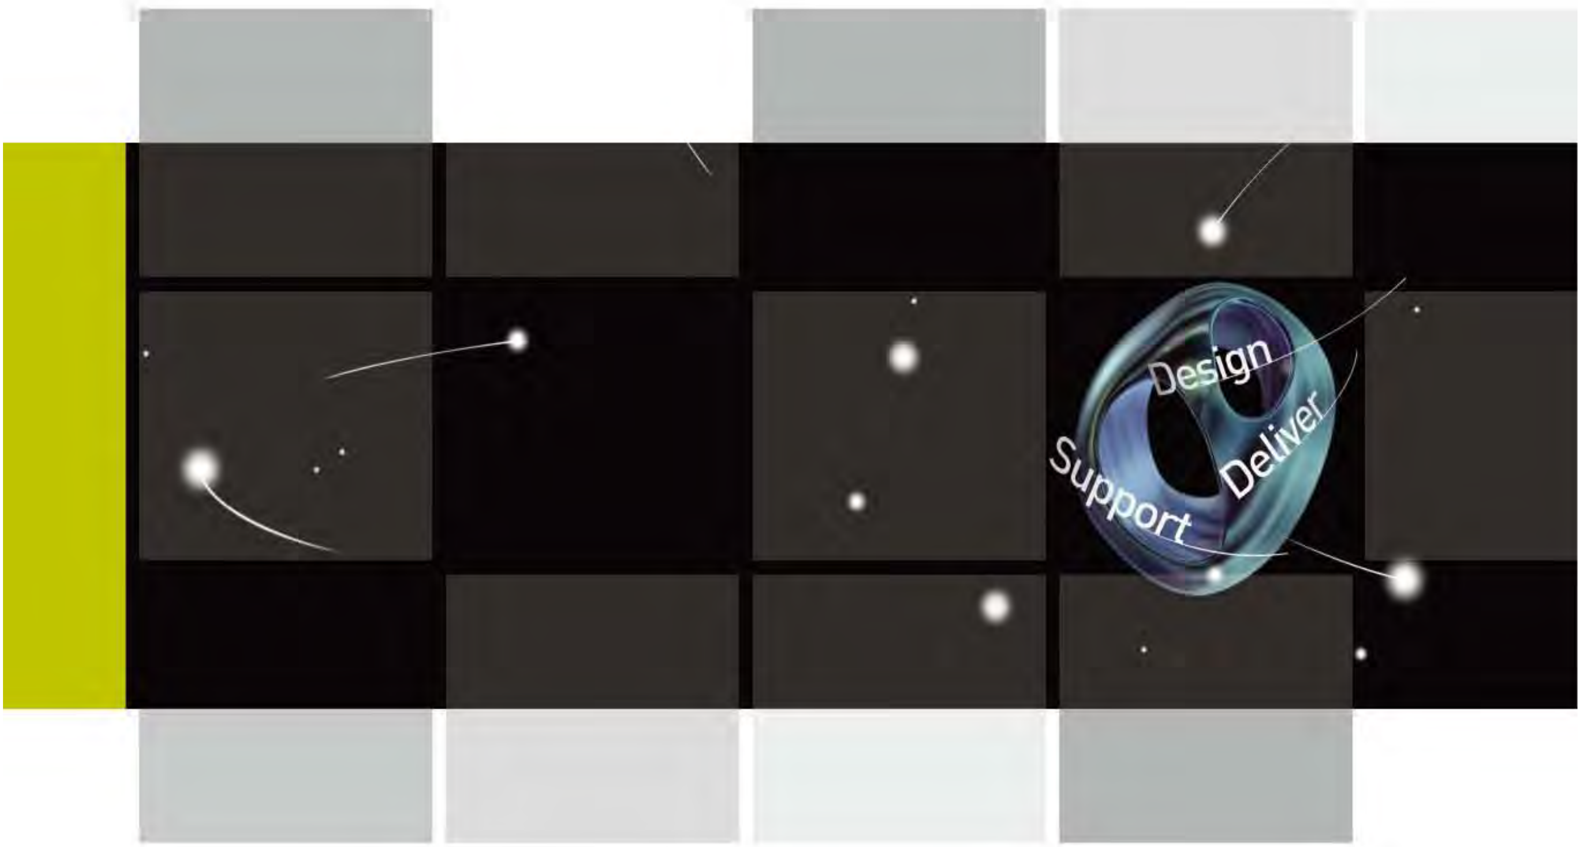
APPENDIX 16E: SUMMARY OF TERRESTRIAL SURFACE WATER QUALITY NON-RADIOCHEMICAL ANALYSIS RESULTS REPORT



Summary of Terrestrial Surface Water Quality Non-Radiochemical Analysis Results (Campaigns 1-6 including WFD)

15011/TN/00102
Issue 02 - Final
August 2010

CONTENTS

1.0 INTRODUCTION

The surface watercourses that currently drain the proposed Built Development Area West are formed from an i nterconnected series of agricultural drainage ditches. These watercourses ultimately discharge water to the foreshore at Hinkley Point through an unnamed watercourse that flows along the boundary between the proposed Built Development Area West and the Built Development Area East.

There are no historical water quality data available for the surface watercourses draining the proposed development area. To characterise the baseline terrestrial surface water quality environment, a m onitoring programme was carried out in 2009. Following the third monitoring campaign the geographical scope of the monitoring area was extended to include those additional watercourses that drain the Southern Construction Phase Area.

This report includes comparison to recently implemented Environmental Quality Standards (EQS) under the Water Framework Directive[1] (WFD) and supercedes the previous summary report entitled 'Summary of Terrestrial Surface Water Quality Non-Radiochemical Analysis Results (Campaigns 1-6)[2]'.

2.0 SUMMARY OF MONITORING PROGRAMME

2.1 Monitoring programme

Terrestrial surface water quality monitoring was undertaken on surface freshwater features (unnamed field ditches and streams) on the Built Development Area West land. Water sample collection and r ecording of *in-situ* water quality parameters such as pH, dissolved oxygen and temperature was undertaken on an approximately monthly basis commencing in January 2009. Six campaigns were undertaken in total, as discussed with the Environment Agency during a consultation meeting held in December 2008. The dates of the 6 sampling campaigns are provided in Table 1 .

Following campaign number 3 in April 2009, the geographical scope of the monitoring area was increased, to cover the Southern Construction Phase Area. As a result, during campaigns 4, 5 and 6, three additional sample locations were added to ensure that a comprehensive baseline of the water quality conditions on the Southern Construction Phase Area was also established.

The locations of the freshwater surface monitoring points are presented in Appendix A. The additional monitoring points on the Southern Construction Phase Area are marked as the surface watercourse sampling sites (SW): SWA (Bum Brook); SWB (Holford Stream); and, SWC (unnamed watercourse).

Table 1 Dates of sampling campaign visits.

Sampling campaign number	Date of sampling visit	Replicate details
1	26th January 2009	No replicate taken
2	2nd – 3rd March 2009	Duplicate taken at SW7
3	14th – 15th April 2009	Duplicate taken at SW9
4	18th – 19th May 2009	Duplicate taken at SW6
5	9th June 2009	Duplicate taken at SWA Additional field blank.
6	15th July 2009	Duplicate taken at SWB

2.2 Southern Construction Phase Area freshwater features

Bum Brook flows from west to east along the southern boundary of the Southern Construction Phase Area land. Bum Brook joins Storgursey Brook approximately 400 m downstream of the Southern Construction Phase Area where it becomes Mill Stream. Sampling site SWA was located at the point at which Bum Brook deviates from the Southern Construction Phase Area boundary i.e. the most downstream point adjacent to the Southern Construction Phase Area land. At SWA, Bum Brook had a wide (approximately 3 to 4 m), shallow channel (approximately 0.3 m in depth), a pebbled bed and a moderate flow velocity (estimated to be approximately 0.25 m/s).

Holford Stream flows eastwards across the Southern Construction Phase Area before flowing from west to north-east between North Moor and Wick Moor. The SWB monitoring site was located on Holford Stream at the approximate point at which the stream crosses the Southern Construction Phase Area boundary. The stream at SWB was shallow (approximately 0.4 m) with no observable flow during the site visits and discoloured with suspended sediments. Bum Brook, and in particular Holford Stream, are important water supply streams to the Bridgwater Bay Site of Special Scientific Interest (SSSI).

The designation of the Bridgwater Bay SSSI[3] is due largely to the communities of plants and invertebrates that are associated with a network of ditches and ponds. Due to the water dependent nature of the SSSI, Holford Stream may be viewed as highly sensitive to potential water quality impacts.

The SWC monitoring site was located on an unnamed drainage ditch close to the Southern Construction Phase Area. This unnamed drainage ditch was found to be dry, or with insufficient water to sample, during every one of the sampling visits, therefore no samples were taken at this site.

2.3 Sample collection

The sample collection methodology and handling of samples was undertaken according to the methods described in the British Standard for Water Quality Sampling[4]. Water samples were collected in 1 litre glass bottles. Where access allowed, samples were collected by direct placement of the sampling bottle below the surface of the stream or ditch facing in an upstream direction. Where direct access to the waters edge was restricted (due to bramble bushes for example), the sample was collected by use of a stainless steel sampling bailer fixed to a pole before transferring to the testing bottles.

In all cases, the sampling procedures ensured that cross-contamination and disturbance of the stream or ditch bed or bank side sediments was prevented. Two subsequent samples were collected at the same time from each sampling location for radiological analysis (radiological analysis results have been reported separately). A record of the sampling activities was undertaken using field record sheets whilst on-site.

Water samples were packaged in coolboxes, refrigerated and couriered to a UKAS/Mcerts accredited laboratory within approximately 24 hours of sampling.

In order to test the validity of the data, quality-assurance duplicate samples were taken during sampling visits 2 to 6 inclusive. Duplicate samples were taken at the same time and labelled in a standard way i.e. the testing laboratory would have no indication that the samples were duplicates. An additional 'field blank' (consisting of ultra-pure water) was prepared during sampling campaign 5 and submitted for analysis, to act as further quality assurance of the laboratory testing. The locations at which the duplicate samples were taken, are given in Table 1 .

2.4 Chemical analysis suite

The suite of chemical analyses employed during the surface water monitoring campaigns covers a wide range of chemical parameters to assist in assessing the water quality status of individual surface watercourses and are presented in Table 2.

Table 2 Terrestrial surface water chemical analysis suite.

Determinant	MRV	Units
Suspended solids (@105^{o}C)	5	mg/l
Biochemical Oxygen Demand (BOD) 5 day ATU	2	mg/l
Total Petroleum Hydrocarbons (TPH) (C_8-C_{35})	10	µg/l
Zinc (total)	5	µg/l
Boron (dissolved and total)	5	µg/l
Chloride	1	mg/l
Ammoniacal nitrogen	0.01	mg/l
Nitrate (as N)	1	mg/l
Total hardness ($CaCO_3$)	10	mg/l
Sodium	0.1	mg/l

Table notes: MRV is the 'Minimum Reporting Value'

Note that testing of 'total boron' was added to the suite of analysis after terrestrial campaign 3 that subsequent data may be compared to Environmental Quality Standard (EQS) values with greater confidence.

2.5 *In-situ* water quality monitoring

In-situ water quality monitoring was undertaken at each sampling location on each monitoring visit. Given the shallow nature of the ditches and streams, only surface readings were possible.

At each site, pH, dissolved oxygen (as % saturation and mg/l) and temperature were recorded using pre-calibrated field meters and probes.

For the first campaign (January 2009), the reliability of the *in-situ* measurements of pH was questioned and a malfunctioning pH probe was suggested as a possible cause of unsatisfactory results. In response, an electronic pH probe (Hanna Instrument 98107 pH ep model type) and a Quanta-G Dissolved Oxygen meter were deployed during the second and subsequent sampling campaigns. All field measuring equipment was pre-calibrated prior to use as per the manufacturers' guidelines. The pH results from the first campaign have been discounted and where pH results are required for subsequent comparison against WFD EQSs for example, a proxy pH value has been used, specifically the mean value across all other campaigns.

3.0 FRESHWATER ENVIRONMENTAL QUALITY STANDARDS

The water quality guidance values that have been used to examine the data from the terrestrial surface water monitoring campaign are detailed in Table 3. The suite of water quality parameters was determined in consultation with the Environment Agency in December 2008 and allows comparison with freshwater EQS values and those of the Water Supply (Water Quality) Regulations 2000[5] Drinking Water Standards (DWS).

In December 2009, Directions[6&7] were issued by the UK government to the Environment Agency which allowed revised water quality environmental standards developed by UKTAG (United Kingdom Technical Advisory Group) for the WFD to be implemented. The WFD EQS values are presented in Table 3 alongside previous standards.

Bum Brook and H olford Stream discharge into the WFD[1] waterbody named 'Stogursey Brook' (see Appendix D for the waterbody table for Stogursey Brook, taken from Annex B of the South West River Basin District Management Plan[8]). The Stogursey Brook waterbody is currently at overall 'Poor' WFD standard with the objective of reaching 'Good Ecological Status' by 2015. A number of water chemistry elements are specifically listed in the Stogursey Brook waterbody table as supporting elements to the status description (where data has allowed specific characterisation) and t hese have been use d, together with the target status of 'Good' to define appropriate EQSs (see Appendix D and Table 3). In each case, the highest available status score has been chosen, given that the WFD dictates no deterioration of any component water quality parameter should occur. Thus the EQS most likely to be used as a regulatory threshold (by the Environment Agency) has been selected for monitoring data assessment purposes. The drainage ditches in the north of the study area discharge directly to the foreshore, but for the purposes of this assessment they have been compared to the Stogursey Brook WFD EQS standards.

The determination of WFD EQSs for Total Ammonia, Biochemical Oxygen Demand (BOD) and Dissolved Oxygen (DO) are linked to Alkalinity, as set out in the WFD Directions, 2009. In order to allow comparison with the WFD standards Alkalinity has been retrospectively calculated as it has not been determined by sample analysis during the monitoring campaign. Alkalinity has been calculated using hardness and pH values and standard equations for dissociation. It should also be noted that many of the EQS values listed relate to annual mean values or percentile values. Comparison of the Hinkley Point freshwater data with EQS values of this type should be co nsidered with caution, given that annual mean figures and percentiles are derived from a limited number of sampling campaigns.

Table 3 Guideline Water Quality Standards used to assess the water quality of terrestrial surface water features at Hinkley Point.

4.0 RESULTS

Summary results from the chemical analyses (non-radiological) of collected water samples are presented in Appendix B. Sections 4.1 and 4.2 compare the analytical results to:

- Environmental Quality Standards and Drinking Water Standard values set prior to the implementation of the WFD; and
- Environmental Quality Standard values set by the Water Framework Directive and implemented by the River Basin District Directions 2009[6&7].

4.1 Results compared against Pre-Water Framework Directive EQS values

The data across all campaigns indicate that all tested parameters for monitoring sites within the Built Development Area land are within a normal range for lowland freshwater systems and below the DWS and EQS guidelines with the occasional exception of suspended solids and BOD. There was also one individual exceedance of the ammonium DWS, recorded at SW9 during the March 2009 campaign.

Data for the additional sampling locations associated with the Southern Construction Phase Area also indicated the majority of parameters to be within a normal range for lowland freshwater systems and below the freshwater EQS and DWS guidelines. The only exception was BOD which was equal to the 6 mg/l freshwater EQS standard in Bum Brook (SWA) during the May 2009 campaign.

Discrete terrestrial surface water data for suspended solids, BOD and ammonia collected during the 2009 monitoring campaign are presented in Figure 1, Figure 3 and Figure 5 respectively. Mean data for suspended solids, BOD and ammonia (for each monitoring site) are presented in Figure 2, Figure 4 and Figure 6 respectively. The data show a broad consistency of all other parameters (i.e. within a normal expected range) across all sampling locations and between different sampling visits.

The number of sampling locations that were dry at the time of sampling increased through the spring and into the summer sampling campaigns and reflects the ephemeral nature of the drainage ditches. During the July sampling visit, there were only three sampling locations that had sufficient water depth to allow samples to be collected (SW6, SWA and SWB). The locations that were found to be dry during each sampling visit are presented in Table 4 below.

Table 4 Sampling locations that were found to be dry during sampling visits.

Campaign 4 (April)	Campaign 5 (June)	Campaign 6 (July)
SW2	SW2	SW1
SW9	SW7	SW2
SW11	SW9	SW3
SWC	SW11	SW5
	SWC	SW7
		SW9
		SW11
		SWC

All duplicate samples yielded similar laboratory data results, which provides confidence in the quality of the laboratory analysis. The field blank sample yielded analytical results that were all below the limits of detection. These data are presented in Appendix B.

During campaign 5, the sample taken from Bum Brook, SWA (and replicate SWAA) was found to have a relatively low concentration of sodium, a relatively high concentration of nitrate and a relatively low hardness value (compared to other sample results during this campaign). Consideration of the location of this stream and the flow in Bum Brook, which at the time of sampling was found to be greater than that in the other surface water features, may help to explain these observations. Bum Brook flows along the southern boundary of the SSA land and is the most southerly of all the water features sampled. The upstream catchment area is likely to be larger than most of the other water features discussed, given that many of the other water features are slow flowing, stagnant or dry. The catchment area for Bum Brook is agricultural land and it is likely that some nitrates from agricultural fertilisers (both recently and historically applied) will contribute to concentrations measured in Bum Brook. The increased distance from the sea and the larger flow volumes (relative to other water features) may have the effect of diluting any contributions of sodium and any divalent salts (e.g. calcium and magnesium, that are responsible for water hardness) from groundwater contributions and/or sea spray. Although results from Bum Brook are broadly consistent across the three sampling campaigns in which it was sampled, the observations noted above were most pronounced during campaign 5.

A summary of the *in-situ* readings are presented in Appendix C. The pH results across all sampling campaigns ranged from 6.80 to 8.30 pH units, which represented a range of conditions from close to neutral to slightly basic. All pH readings across the site fall within EQS limits and are typical of lowland freshwater watercourses.

A wide range of dissolved oxygen concentrations, ranging from 21.2 % (2.4 mg/l at 11.3 ^{o}C) to 96.3 % (11.3 mg/l at 8.5 ^{o}C) was recorded across the six campaigns. This is to be ex pected in shallow, slow flowing, freshwater watercourses. The minimum and maximum values for each campaign are presented in Appendix C. Localised reductions in dissolved oxygen concentrations may occur where shallow water depths (which may result in increased temperature), stagnant flow and elevated BOD concentrations prevail. Conversely, increases in dissolved oxygen concentrations may result from the photosynthetic action of algal and submerged macrophyte populations for example. The drainage watercourses within the Built Development Area West are not considered suitable to support fish populations due to their ephemeral nature and comparisons to dissolved oxygen environmental quality standards for the protection of fish are not appropriate. The inclusion of EQS values for all sampling location points in the summary tables, presented in Appendix B is for information purposes only.

Holford Stream and Bum Brook may support fish populations of limited abundance and diversity, due to the constraints of the physical fish habitat quality. The fish species likely to be present are sticklebacks, cyprinid species and eels. For these watercourses it is therefore appropriate to compare the field data from the relevant sampling sites with dissolved oxygen standards for cyprinid fish (2006/44/EC)[9]. This comparison is presented in the summary results table (Appendix B) and Table 5. Comparison of dissolved oxygen results with EQS percentile values should be made with caution, given that the results for Holford Stream and Bum Brook are based on a limited data set i.e. only three *in-situ* measurements. The comparison with the Freshwater Fish EQS values suggest that baseline dissolved oxygen concentrations are low within both Holford Stream and B um Brook (note that dissolved oxygen concentrations within Bum Brook meet 100 percentile guideline and imperative standards).

Table 5 Comparison of *in-situ* dissolved oxygen (DO) concentrations for Holford stream and Bum Brook with standards specified in Directive 2006/44/EC

DO EQS (Cyprinid Waters)	Holford Stream, mg/l (mean value +/- st. dev. bracketed)	Bum Brook, mg/l (mean value +/- st. dev. bracketed)
>=8$^{50\ G}$	3.8 ^{50*} (4.52 +/- 0.86)	7.3 ^{50*} (7.05 +/- 2.25)
>=5$^{100\ G}$	5.3 ^{100*} (4.52 +/- 0.86)	9.2 ^{100*} (7.05 +/- 2.25)
>=7$^{50\ I}$	3.8 ^{50*} (4.52 +/- 0.86)	7.3 ^{50*} (7.05 +/- 2.25)

Table notes:
^{50} 50 percentile value
^{100} 100 percentile value
^{G} Guideline value
^{I} Imperative value
* Based upon 3 *in-situ* measurements

4.2 Results compared against Water Framework Directive EQS values

All the ditches that flow across the Built Development Area i.e. all watercourses other than Holford Stream and Bum Brook, drain to the foreshore and do not flow into a WFD freshwater waterbody unit. Comparison of all data has been made with WFD EQSs for completeness (see Appendix B for summary of results).

The concentration of dissolved oxygen from all locations was found to be below the EQS values set by the WFD. A comparison of the dissolved oxygen data from Holford Stream and Bum Brook with the WFD Environmental Quality Standard is presented in Table 6. Comparison of dissolved oxygen results with EQS percentile values (WFD EQS is a 10 percentile value) should be made with caution, given that the results for Holford Stream and Bum Brook are based on a limited data set i.e. only three *in-situ* measurements. The comparison with the WFD EQS values, which is consistent with the discussions above, suggest that baseline dissolved oxygen concentrations are low within both Holford Stream and Bum Brook. Dissolved oxygen concentrations within all other watercourses may be expected to be low, given the shallow depths and ephemeral nature of these drainage ditches.

Table 6 Comparison of *in-situ* dissolved oxygen (DO) concentrations for Holford Stream and Bum Brook with standards specified in the Water Framework Directive

DO EQS, % saturation	Holford Stream, mg/l	Bum Brook, mg/l
70[10 ^]	36 [10*]	51.4 [10*]

Table notes:
[10] 10 percentile value
[*] Based upon 3 *in-situ* measurements

New EQS values introduced for pH and temperature under the WFD, have allowed the *In-situ* results to be compared against revised statutory limits. The pH and temperature values at all sites were found to fall within the normal range specified under the WFD EQS.

Recorded concentrations of ammonia were found to be below the WFD EQS at all sites. The ammonia concentrations recorded at SW9, which exhibited a single elevated ammonium concentration when compared to the drinking water standard, were below those standards set by the WFD.

BOD concentrations did not meet the EQS set by the WFD at locations SW2, SW3, SW5, SW6, SW11 and SWA (Bum Brook). BOD results are presented in Figure 3 and Figure 4.

Sections 4.3, 4.4 and 4.5 present further detail with regards to suspended solids, BOD and ammonia, which have all been found to exhibit elevated concentrations relative to some or all Environmental Quality Standards.

4.3 Suspended solids

At all sites within the Built Development Area West, suspended solids were consistently recorded at concentrations in excess of the Freshwater EQS (see Figures 1 and 2). The mean suspended solids concentrations for all sites on the Built Development Area was found to be greater than the EQS value. The maximum recorded value for suspended solids, was 492 mg/l at SW3.

There were no exceedances on the Southern Construction Phase Area, with regard to suspended solids concentrations.

The WFD does not include a suspended solids EQS.

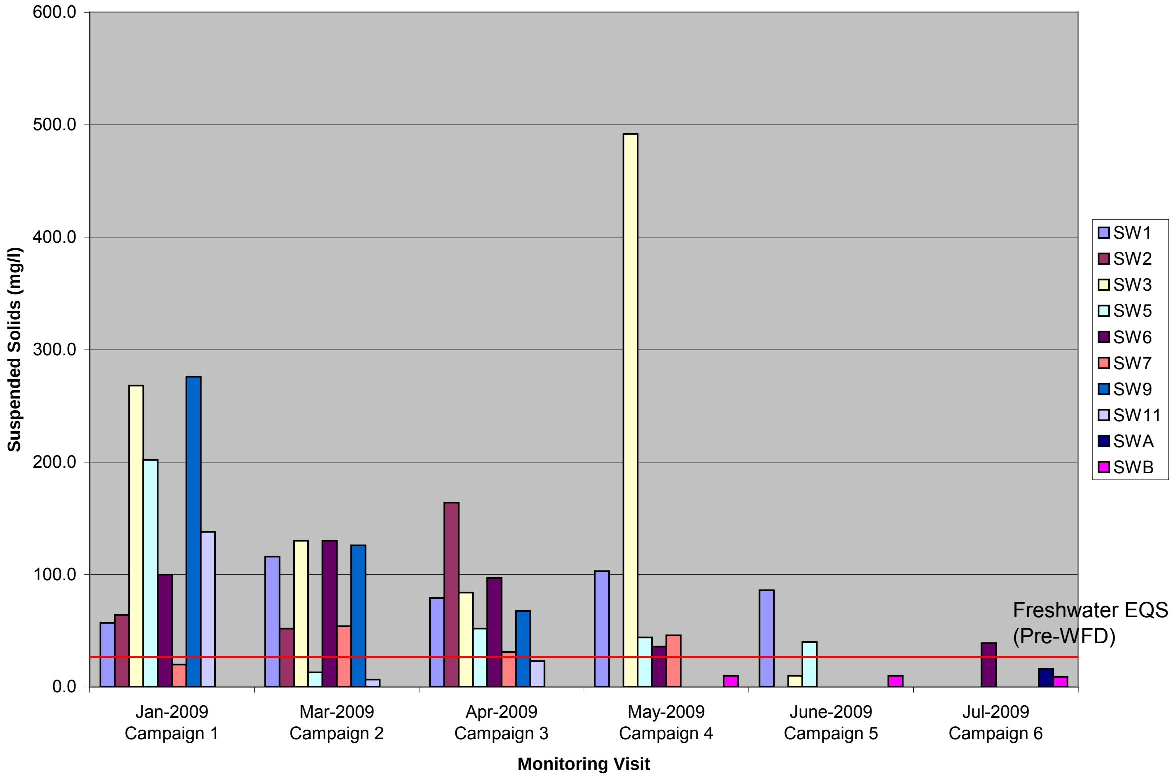

Figure 1 Terrestrial surface water suspended solids data.

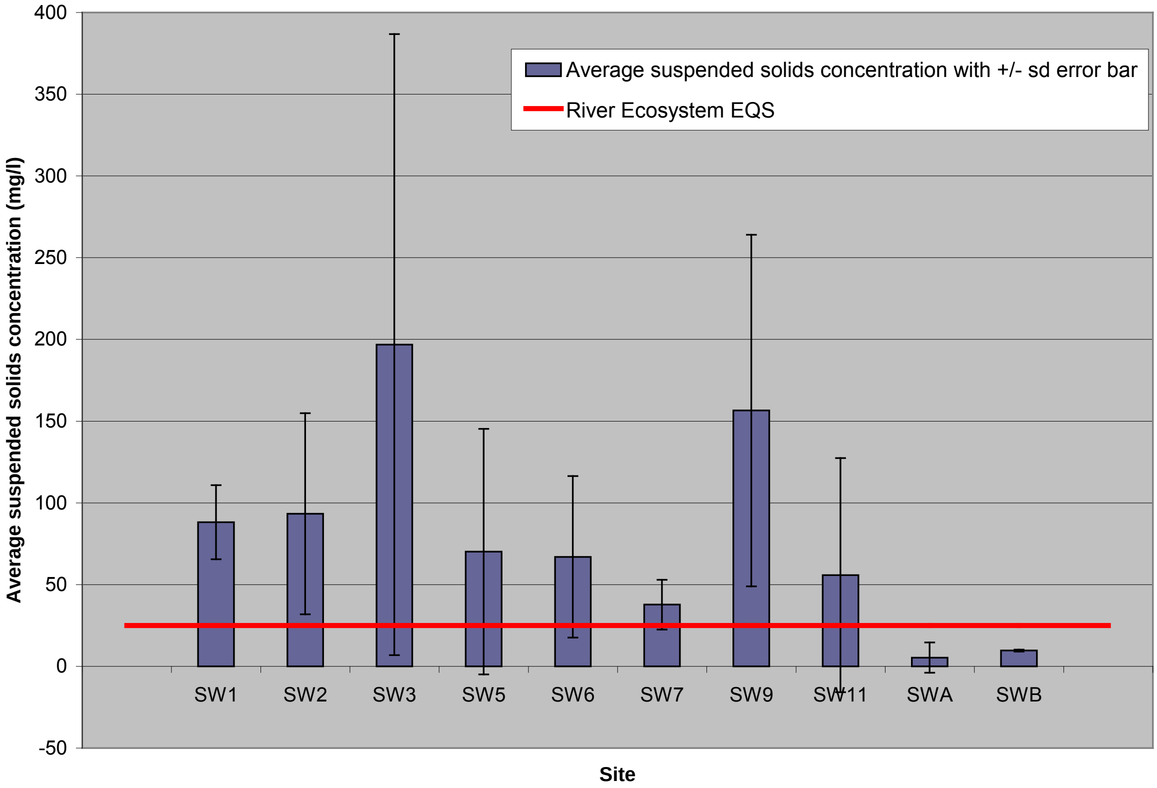

Figure 2 Terrestrial surface water suspended solids data – overall mean for each monitoring site. Standard deviations are presented as error bars for each site.

4.4 Biochemical oxygen demand

A number of individual samples were found to exceed the freshwater EQS (both pre- WFD and WFD) for BOD (see Figures 3 and 4). The maximum recorded value for BOD across all campaigns (value of 15.6 mg/l) was recorded at SW11 during the January sampling campaign.

The pre- WFD freshwater EQS for BOD is taken from the Surface Waters (River Ecosystem) (Classification) Regulations 1994[10]. The adopted class for comparison purposes is Class RE3. In order to compare against the EQS value as intended, the 90th percentile of the BOD data should not exceed 6 mg/l. The 90th percentile data is presented on Figure 4, which shows that sites SW3, SW5, SW6 and SW11 recorded results above the EQS threshold. All these sites are associated with the Built Development Area West.

The WFD EQS for BOD is the same for all sample sites i.e. 5 mg/l as a 90th percentile. The WFD EQS is also shown on Figure 4. The revision of the EQS under the WFD means that SWA (Bum Brook) also fails the new standard.

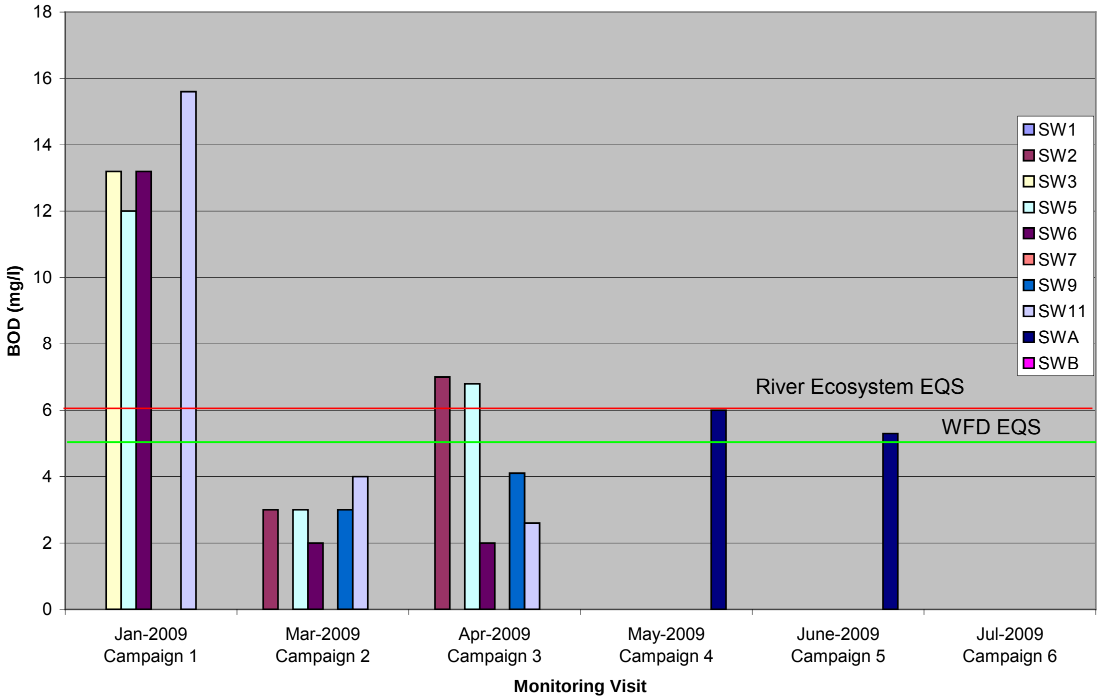

Figure 3 Terrestrial surface water BOD data.

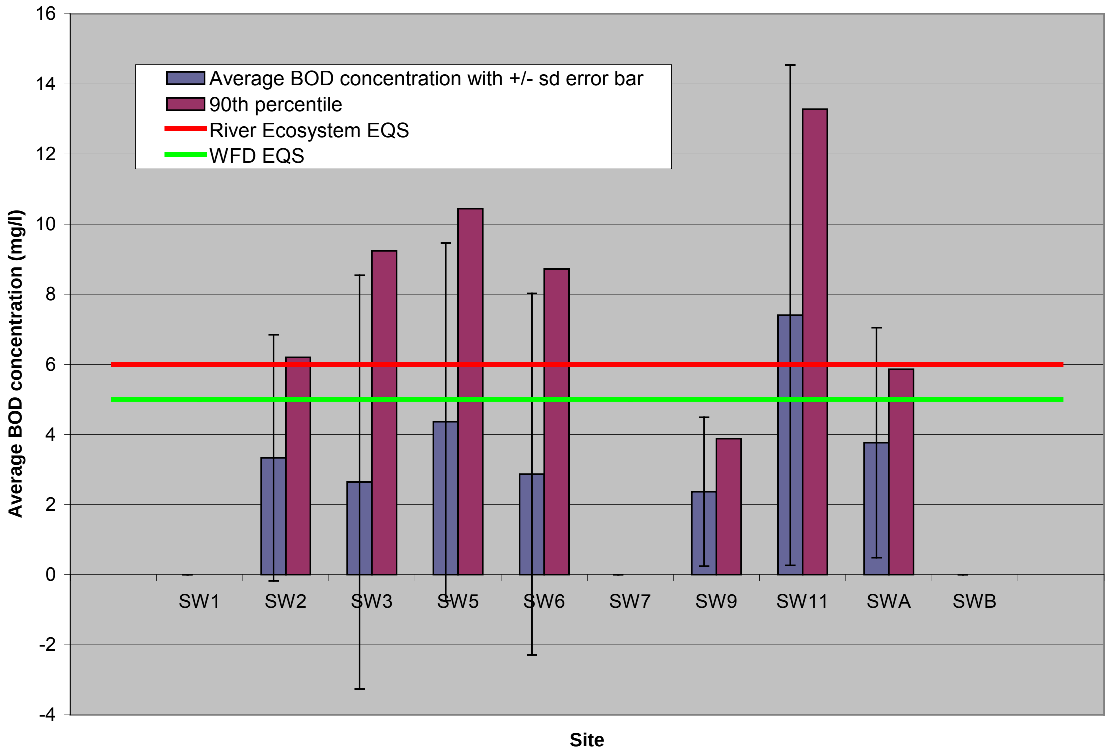

Figure 4 Terrestrial surface water BOD data – overall mean and 90th percentile data for each monitoring site. Standard deviations are presented as error bars for each site.

4.5 Ammonia

One exceedance of ammonium, with a value of 0.62 mg/l (exceeds DWS value of 0.5 mg/l, but below the lowest pre- WFD freshwater EQS of 1.0 mg/l) was recorded at SW9 during the March sampling campaign (see Figure 5 and Figure 6).

The DWS for ammonium is taken from the Water Supply (Water Quality) Regulations 2000. In order to compare against the ammonia threshold as intended, the 90th percentile of the ammonia data should not exceed 0.5 mg/l. The 90th percentile data is presented on Figure 6, which shows SW9 as being in excess of the drinking water standard.

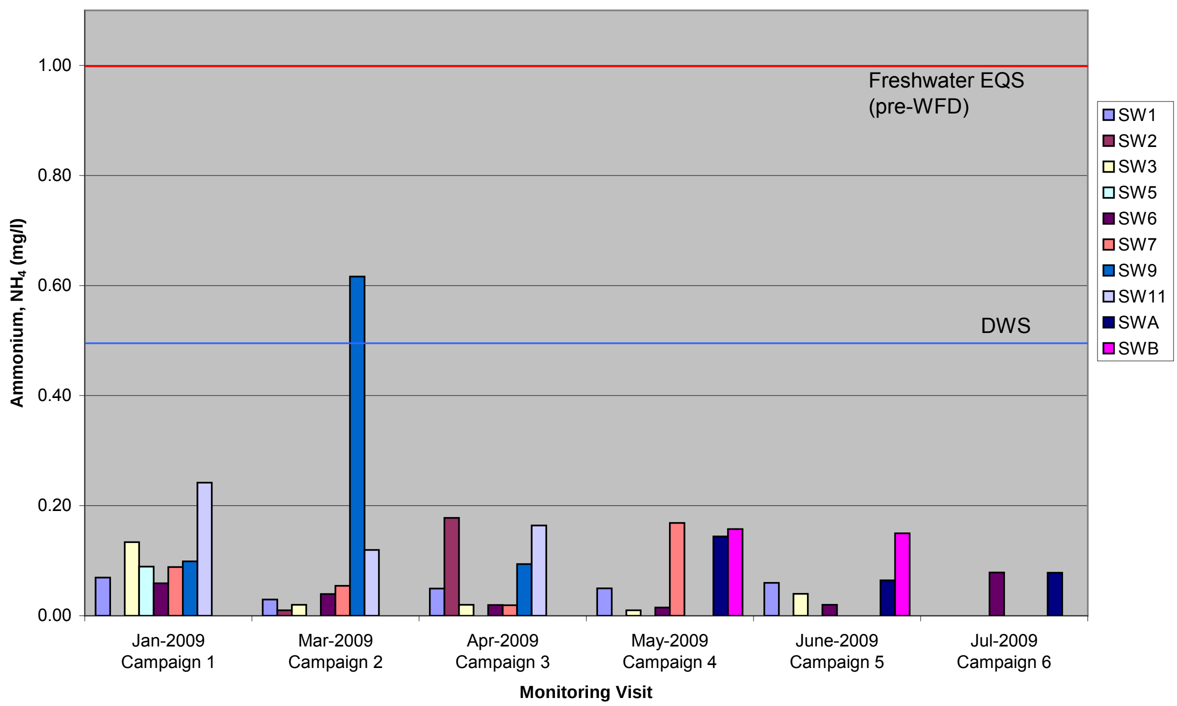

Figure 5 Terrestrial surface water ammonium data.

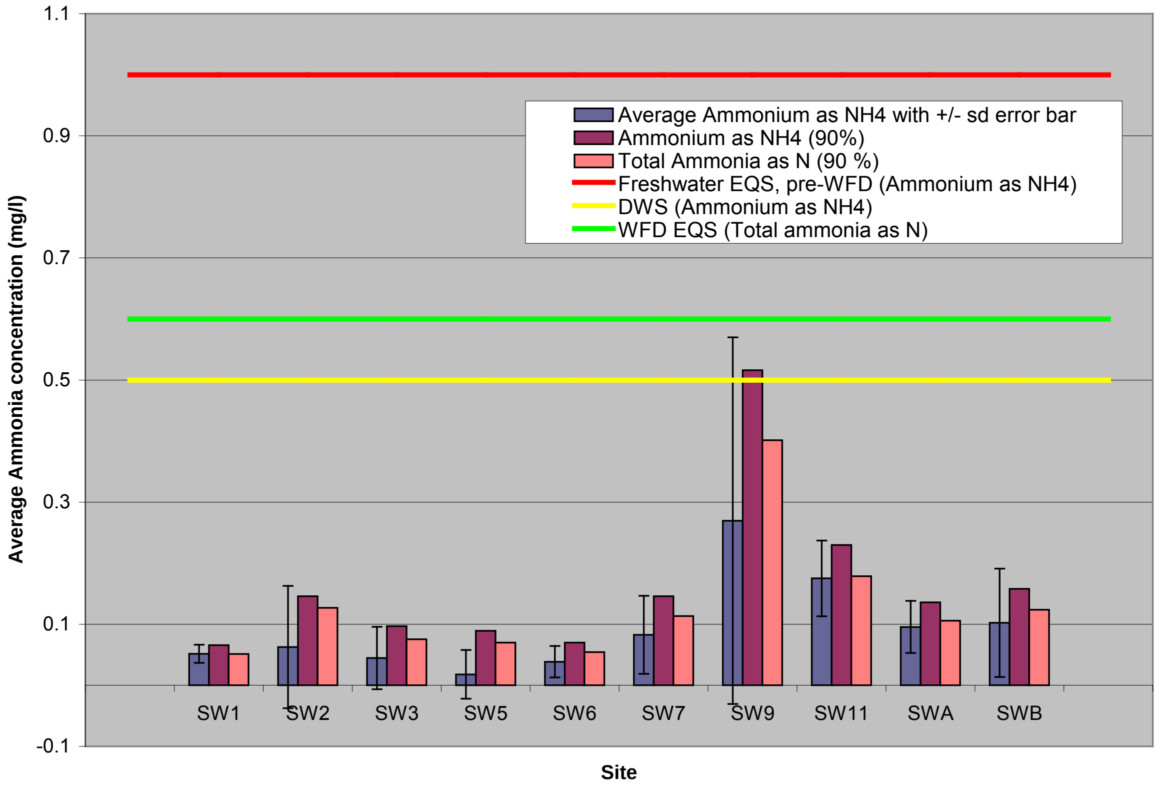

Figure 6 Terrestrial surface water ammonia data. Comparison with pre-WFD and WFD standards are presented.

Ammonia concentrations do not exceed the EQS set by the WFD, at any of the monitoring locations. The WFD EQS (90th percentile, Total Ammonia as N) has been included on Figure 6 to allow a visual comparison between Ammonia thresholds. The WFD EQS is determined by reference to the WFD Directions and the Stogursey Brook predicted current and predicted quality status for Ammonia (within the South West River Basin Management Plan). The WFD Directions set standards based on alkalinity ranges and the Stogursey Brook predicted status by 2015 is one of 'Good Status' for Ammonia. These factors combine to dictate a WFD EQS of 0.6 mg/l (Total Ammonia as N).

5.0 CONCLUSIONS

The terrestrial surface watercourses on the Built Development Area West land and the Southern Construction Phase Area were generally turbid and slow flowing and often contained deposits of cut vegetation from agricultural activities on the surrounding fields. The threshold level exceedances that have been found for various parameters are considered typical for this type of watercourse.

Baseline dissolved oxygen concentrations are low within both Holford Stream and Bum Brook, the only two watercourses that are considered to be able to support fish populations and which are within the catchment area of the Stogursey Brook WFD waterbody.

Elevated concentrations of BOD and suspended solids were a regular occurrence across the sampling programme. Elevated concentrations of these parameters commonly occur in shallow, heavily sedimented surface waters, particularly in field drainage ditches associated with agricultural land. Temporal variation in BOD, in watercourses of this type may be attributable to a range of factors including prevailing weather conditions (e.g. rainfall) and inputs of organic matter (e.g. cut vegetation). Temporal variation in suspended solids concentrations may be attributable to re-suspension of fine bed sediments.

The single occurrence of elevated ammonia may be due to an isolated instance of agricultural runoff or development of low dissolved oxygen concentrations. It should be noted that the elevated ammonia reading is relative to the DWS and is therefore a precautionary comparison benchmark to adopt for this type of watercourse i.e. these field drainage ditches will not be used for drinking water. All ammonia data is found to be below the revised thresholds presented within the Water Framework Directive.

In summary, the water quality results are representative of what would be expected for shallow, agricultural drainage ditches that typically show wide variation in water quality and flow characteristics which may depend for example, on rainfall intensity and associated surface drainage from surrounding fields.

APPENDIX 18A: NUMERICAL HYDRODYNAMIC MODELLING DEVELOPMENT

18A.1 Environmental Regulatory Requirements

18A.1.1 The following text is taken directly from Ref. 18A.1, which provides the current environmental regulatory guidance appropriate to considerations of New Nuclear Build in the UK.

a) Introduction

18A.1.2 *“There are plans to build a number of new nuclear power stations in England and Wales over the next decade or so. All of these power stations will be located on the coast to enable sea water to be used as the prime coolant. At each site, sea water will be extracted, used for cooling, and returned to the sea with temperatures elevated by about 10^{o}C. Flow rates will be of the order of 100 m^{3}/sec (cumecs), so potentially the thermal and consequential ecological impact on the receiving water will be large according to the dilution and dispersion available.*

18A.1.3 *‘This thermal and ecological impact on the receiving waters cannot be avoided, but it must be minimised.*

18A.1.4 *‘Whilst the thermal impact of the discharge is of prime interest, the discharge may have secondary impacts, such as*

- *Changes in speciation of ammonia as a result of the elevated temperatures.*
- *Changes in salinity as a result of the abstraction/discharge regime.*
- *Changes in DO as a result of elevated temperature.;*
- *Discharges of anti-fouling agents and their by-products.*
- *Discharges of other process chemicals.*

18A.1.5 *‘Hydrodynamic modelling forms an essential part of the scheme design. It is needed to ensure that:*

- *The abstraction is located so as to minimise ecological and fisheries impacts, and;*
- *The abstraction and discharge points are located such that interaction between the two is minimised, and;*
- *The impact of the thermal plume is understood and minimised, particularly in sensitive areas, and;*
- *Any secondary impacts are understood and minimised, particularly in sensitive areas.*

18A.1.6 *'This paper aims to outline Agency requirements for the modelling that must be undertaken. It does not attempt to specify in detail the type of model to be used or the modelling runs that are required – the discharger is expected to produce the detailed specification for the modelling. This specification should be agreed with the Agency on a site-by-site basis.*

18A.1.7 *'Note that the use of the term "Mixing Zone" below refers to the part of a body of surface water within which a standard is exceeded. In tidal waters this can be temporally and spatially variable.*

18A.1.8 *'For example, if the particular standard under consideration is a maximum elevation of temperature of no more than 2^{o}C above ambient, then the "Mixing Zone" is the volume of water, in 3-D, within which the water temperature can be reasonably expected to be 2 or more degrees above ambient at some time during the lifetime of the plant. In this example, the "Mixing Zone" is the 3-D envelope around the discharge point encompassing all locations where, when the discharge is at its maximum permitted temperature, the instantaneous temperature elevation may be above 2^{o}C at some time. It will be much larger than any instantaneous zone within which the temperature elevation is 2^{o}C or more.*

18A.1.9 *'Alternatively, if the standard under consideration is a 98%ile temperature of 23^{o}C over a year, then the "Mixing Zone" is the 3-D envelope around the discharge point encompassing all locations where the temperature is predicted to exceed 23^{o}C for more than 2% of the time. The size of this "Mixing Zone" may be small when compared to the worst-case instantaneous impact of the discharge.*

18A.1.10 *'Clearly, the "Zone of Influence" (of elevated temperature) will extend beyond the "Mixing Zone" as it is defined here."*

b) Agency Requirements

18A.1.11 *"Our requirements for the thermal plume modelling (and post-project appraisal) are summarised as follows:*

- *Modelled output to provide information in 3-D.*
- *Model(s) must be suitable for the application(s).*
- *Not limited to the use of one model – different model types can support and complement each other, for example an excess temperature model looking at different discharge temperature elevations, run over relatively short periods for a number of different scenarios, and a long-term absolute temperature model.*
- *Model(s) must be demonstrated to be suitably calibrated and validated – validation against existing thermal plumes if possible, including the use of aerial or satellite imaging.*
- *Model(s) to comply with Agency standards for hydrodynamic model calibration/validation.*
- *Model(s) to be independently audited – audit report(s) to be provided.*

- *Model(s) to be available for use over period of at least 10 years from date of commissioning of the power station, and beyond that for as long as there is(are) no suitable alternative(s) available.*
- *Agency will require access to the model(s) over the lifetime of the power stations.*
- *Output to represent both absolute temperature and excess temperature above background, both in the near/mid-field and in the far-field.*
- *Results to include the effects of tidal currents, residual currents, wind driven currents, turbidity, solar insolation, cloud cover, air temperature, surface cooling including the effect of wind, river flows, river temperature, thermal and saline stratification, seasonal effects (including short-term extreme temperature events), and sedimentation and erosion.*
- *Results to cover a range of plausible scenarios of climate-change driven rises in air and sea temperatures and sea-levels over the planned life-time of the station.*
- *Results from alternative abstraction and discharge locations, including options to discharge near-bed, mid-water-column, or near-surface, and utilising different outfall designs, as appropriate.*
- *Maps to show locations of designations, sensitive waters, relevant sensitive receptors, etc.*
- *Mixing Zones appropriate to the various thermal standards to be presented in 3-D, based on the statistics of the standard (e.g. annual average, maximum, 98%ile).*
- *Where a Mixing Zone relates to an instantaneous statistic (such as maximum value), then as far as is practicable, some indication of the variation of the duration of exceedence over the Mixing Zone.*
- *In addition to the presentation of the overall Mixing Zones, various instantaneous representations of the temperature field are needed to enable an understanding of typical conditions.*
- *Detailed impact assessment inside the Mixing Zones (and outside if considered appropriate) for all relevant receptors (flora and fauna throughout the water column, on and within the sea bed, and in the inter-tidal zone) to be assessed and discussed.*
- *Relevant statistics of the mixing zones: e.g. area, volume, proportion of estuarine cross-section, proportion of time threshold value exceeded.*
- *Post-scheme appraisal within 5 years of commissioning to validate (or not) the model predictions – based on field observations, satellite or aerial imaging, etc.*
- *If necessary, the re-calibration and validation of the model(s) following post-scheme appraisal.*

18A.1.12 *'Our requirements for the modelling of secondary impacts are essentially the same. Any models used will need to incorporate water quality modules suitable for the processes being modelled."*

18A.2 HPC Model Development

a) Organisational Arrangements

18A.2.1 In complying with the guidance set out above, EDF Energy first established an organisational framework within the British EDF Estuarine and Marine Studies (BEEMS) programme of NNB-related studies (see **Volume 2**, **Chapter 19**) which placed an independent and highly expert team in control of both model specification and quality assurance roles.

18A.2.2 A data centre to current best practice standards was established within this framework and a wide variety of studies established in order to secure baseline oceanographic data in the vicinity of Hinkley Point (see **Volume 2, Chapters 17, 18 & 19**). This included an extensive bathymetric survey effort utilising a number of remote sensing techniques and allied ground truthing, resulting in a wide field composite bathymetry.

18A.2.3 A pair of separate, appropriately qualified, contractors were then charged with establishing and developing separate numerical hydrodynamic models, taking best advantage of the physical data that had been, as was continuing to be, gathered in the field. One of these models simulated excess temperatures, the other absolute temperatures.

18A.2.4 Model codes were not accepted into actual use within BEEMS until they had successfully completed the calibration and validation processes, satisfying specific acceptance criteria laid down by the auditing team.

b) Strategy

18A.2.5 The following text is largely derived from Ref. 18A.2.

18A.2.6 The modelling methodology for the proposed HPC cooling water (CW) system adopted the following approach:

- *Stage 1. Setup and validation of 2 different models against field data (hydrodynamics and thermal plume)*
- *Stage 2. Use of the validated models to examine 4 possible options for the CW configuration for HPC.*
- *Stage 2. Review. The preferred CW option on environmental and recirculation grounds was then selected by EDF Energy and then subjected to engineering refinement to produce a proposed design.*
- *Stage 3. Results from modelling the proposed design both alone and in combination with the discharge from HPB*
- *Stage 3 Review*
- *Stage 3a. Results of modelling the final configuration after any required model setup refinement following the Stage 3 review.*

18A.2.7 The critical reviews at Stage 2 and 3 were undertaken to validate that the models were adequate for purpose. At these reviews it was envisaged that refinements to the model setups might be required if significant discrepancies with field observations or between model outputs were found. Changes to model setups would then require a rerun of the appropriate modelling stage.

18A.2.8 The Stage 2 review (Ref. 18A.3) presented an initial evaluation of the results of applying the two different validated models to the four options for the HP C CW configuration. These options were compared on environmental grounds in Ref. 18A.4. A preferred configuration option was then selected by EDF Energy and subjected to engineering refinement to produce a final design. This design was then modelled alone and in combination with the HPB discharge in Stage 3.

18A.2.9 The Stage 3 model outputs were then subject to detailed review. Both models replicated the hydrodynamic conditions well but there remained questions about the quality of the thermal predictions due to the limited thermal calibration data that was then available. To fill this gap, additional time series data on the temperatures recorded at the condenser intakes of the HPB station were obtained from EDF Energy.

18A.2.10 The Stage 3 review did identify thermal validation issues which led to changes to the model setups. These changes improved the thermal performance of the models without changing their hydrodynamic performance. The changes necessitated a rerun of Stage 3 modelling with what was by then the final design for the HPC CW configuration.

c) The models used

18A.2.11 For HPC, two hydrodynamic models have been applied to the problem of modelling flow dispersion from the proposed power station. These were:

- *General Estuarine Transport Model (GETM) version 2.21*
- *Delft3D version 3.27 for the initial work and version 3.28 (July 2010 release) for the latest configurations presented*

18A.2.12 These two numerical models, which have very different approaches, were used to quantify the likely uncertainty around the modelling approach and therefore produce a quantified estimate of the likely thermal impact and an associated estimate of error.

18A.2.13 The GETM model calculates the effect of the power station by running a reference run (without power station), simulating an entire annual cycle, using a full heat gain and loss implementation. Meteorological data from the ECMWF (European centre for medium range weather forecasting) reanalysis data is used to force the model, so that incident radiation, cloud cover, humidity, wind speed and long wave radiation are included. A configuration run is then performed over the annual cycle, with the power station's proposed discharge included. The net effect of the power station is derived by subtracting the reference run from the configuration run. The most significant difference between the runs being that the discharge plume will have an increased temperature and therefore the long wave radiation will be greater, it will also potentially have higher evaporative heat loss, which is humidity and wind speed dependant.

18A.2.14 The modelling of the heat cycle allows full annual runs to be performed, with winds and other meteorological events, so that realistic estimates can be made of the likely plume variability. In order to perform such long runs, yet still maintain, good vertical and horizontal resolution the runs are performed on a parallel processor.

18A.2.15 As noted above, guidelines on thermal plume modelling for New Nuclear Build, produced by the Environment Agency in 2010, require that assessments are made using annual data or simulated data such as model output, stating that:

- *'An appropriate time scale is a year, in order to include seasonal variations in air and water temperatures, and other climatic factors, e.g. wind stress, light climate. Other significant variables which show seasonality include river flow, salinity, pH, and tidal range, and the range of variation in these should be defined and considered in any assessment. As the climate varies between years, a representative ('average') year should be defined from a number of years. An appropriate period in this context would be the last 10 years.'*

18A.2.16 The GETM model has been used to address the requirement of seasonal variability and variability due to climatic factors, wind and river forcing because inevitably, in the course of a year a variety of conditions are experienced. This can be analysed to determine the model (and real sensitivity) to a change in any particular parameter e.g. wind direction. The implications for increased sea temperatures can be understood by investigation of the summer periods.

18A.2.17 In contrast the Delft3D model uses an excess temperature model, to calculate the heat loss directly from the discharge of plume. It is a standard approach and has been used in many models such as Telemac. Such models assume that the heat loss from a plume is a function of the temperature of the water and the air speed. These models because they do not seek to emulate "real" from the outset, usually simulate short conditions and are generally not running on a parallel cluster.

18A.2.18 Table 18A.1 lists the various reports allied with the development of the HPC numerical modelling ensemble.

Table 18A.1: HP Thermal Plume Modelling Reports

Model	BEEMS Report Name	Overview of Contents
Delft3D	TR084: HP Thermal Plume Modelling: Delft3D – Stage 1 Model Calibration and Validation. Ref. 18A.5	Detail of the model grid, setups, validation with observations e.g. Current meters, drifters. Comparison with the thermal plume survey.
Delft3D	TR085: HP Thermal Plume Modelling: Delft3D – Stage 2 Model Results. Ref. 18A.6	Results from the initial four CW configuration options for HPC. Comparison of the relative extent of the plume from a cross shore discharge compared to an offshore one. Meteorological scenarios included. Focus on recirculation estimates.
Delft2D	TR042: HP Thermal Plume Modeling: Delft 2D – Implications of tidal power schemes in the Severn Estuary for Hinkley Point C. Ref. 18A.7	Initial report on the likely impact of the Severn barrage proposals on the HP C plume.
Delft3D	TR121: HP Thermal Plume Modelling: Delft3D – Stage 3 Results. Ref. 18A.8	Includes initial results for HPB, HPC and HP B+C, Also includes results from Geomorphology and Meteorological scenarios; including barrage

Model	BEEMS Report Name	Overview of Contents
		scenarios.
Delft3D	TR182: HP Thermal Plume Modelling: Delft3D – Stage 3a Results with the final cooling water configuration. Ref. 18A.9	Results from the final CW configuration (Twin discharge with 4 intakes on two tunnels for HPC). Includes simulations of HPC, HPB and HPB+C.
GETM	TR102: HP Thermal Plume Modelling: GETM – Stage 1 Model validation and verification. Ref. 18A.10	Details of the setup of the GETM model. Comparison with current meters, drifters and tide gauges. Comparison with the thermal plume surveys.
GETM	TR103: HP Thermal Plume Modelling: GETM Stage 2 Results. Ref. 18A.11	Results from the initial four CW configurations.
GETM	TR177: HP Thermal Plume Modelling: GETM Stage 3a results with the final CW configuration. Ref. 18A.12	Results from GETM runs with the final HPC CW configuration. Includes simulations of HPC, HPB and HPB+C. This report supersedes an earlier report (TR088).
Combined	TR040: HP Thermal Plume Modelling: Stage 2 Review -Initial evaluation of the Stage 2 models. Ref. 18A.3	Initial evaluation of the two models (GETM and Delft3D) with a focus on recirculation estimates of the initial four CW configuration options
Combined	TR135: HP Thermal Plume Modelling: Stage 3 Review - Detailed evaluation of the validation of the two Stage 3 models. Ref. 18A.2	Detailed evaluation of the two Stage 3 thermal plume validations against field data.

d) Conclusions of Stage 3 critical review

18A.2.19 The key question for the Stage 3 review to answer was: *'How accurately is the modelling likely to represent the temperature field of the proposed HPC development and also that of the HPB + HPC combined operation?'*

18A.2.20 Fundamental to answering this question, was the provision of a hydrodynamic model that replicated the areas of interest in the Severn estuary specifically relevant to the areas of proposed CW intake and discharge for HPC.

18A.2.21 Once the hydrodynamic validation criteria were satisfied, then validation against the existing HPB thermal plume was used to quantify the likely accuracy of the model. However, the existing plume at HPB has a number of characteristics that make it very difficult to model and it will behave differently from the likely HPC discharge. This Stage 3 review (Ref. 18A.2) includes an account of the validation and comparison of the models against measurements. More extensive accounts of the setups and validations are given in the modellers' Stage 1 reports (Refs. 18A.5 & 18A.10).

18A.2.22 Subsequent to the work conducted by these modellers, which primarily used observational data collected in field campaigns, a data series on the temperatures recorded at the intake at the HPB station became available. This time series is at daily intervals for two years and for two 15 days periods at one minute intervals, in January 2008 and September 2008.

18A.2.23 In conclusion, Ref. 18A.2 states that:

18A.2.24 *'In relation to the hydrodynamic validation both models performed well against tidal elevations for phase and amplitude. Both models gave good (=<10%) representation of the tidal flows across the intertidal zones, which is a difficult challenge. They also gave a good replication of the flood tides to better than 10% of the maximum currents.*

18A.2.25 *'The two models have very different heat formulations; however, both replicate the neap tide conditions well. For spring tides the GETM model indicates higher plume temperatures than the Delft3D model at the HP B inlet, however due to inadequacies in the representation of the HP B discharge by the GETM model the assessment of accuracy is probably not representative of the larger area in the far field of HP B. In general taking the intake comparison, the thermal plume surveys and the comparative areas of the thermal plumes into account it is likely that the GETM model represents a likely upper limit on the thermal impact of HP C and that for modelling of the HP B plume that the Delft3D model provides estimates closest to the true value. However, the GETM model because it simulates a whole year with its natural meteorological variability is expected to give a better estimate of the plume variability than the Delft3D model.*

18A.2.26 *'The review concludes that the models as now setup are fit for purpose for assessing plume environmental impacts. In the far field it is likely that that the GETM model of HP C predicts mean plume temperatures that are approximately 0.5°C greater than those from the Delft3D model. There is sufficient evidence to be confident that the likely true thermal impact lies between the outputs of the two models and that the median between them is a reasonable estimate of true likelihood.'*

18A.3 Subsequent Development

18A.3.1 These models have subsequently been employed to support:

- *Investigation of a variety of meteorological and geomorphological scenarios, bounding both the potential consequences of other local developments, long term morphological change, and plausible developments in climate.*
- *Estimates of the behaviour of the thermal plumes of both HPC and HPB, alone and in combination, and assessments of their potential effects on local receptors.*
- *Estimates of the behaviour of chemical discharges, and assessments of their potential effects on local receptors.*

18A.3.2 Further details of these assessments may be found in **Volume 2, Chapters 17, 18 & 19** and **Appendix 18B** of this ES, together with their supporting references.

18A.4 Compliance with Guidance

18A.4.1 Table 18A.2 provides a series of statements on compliance with Environment Agency guidance on the numerical modelling need (Ref. 18A.1).

Table 18A.2 Compliance of HPC Numerical Modelling Arrangements with Existing Guidance

EA Requirement	Compliance Statement
Modelled output to provide information in 3-D	Met

EA Requirement	Compliance Statement
Model(s) must be suitable for the application(s)	Met (as demonstrated by the validation reports)
Not limited to the use of one model – different model types can support and complement each other, for example an excess temperature model looking at different discharge temperature elevations, run over relatively short periods for a number of different scenarios, and a long-term absolute temperature model	Met – 2 models produced (using Delft3D and GETM respectively)
Model(s) must be demonstrated to be suitably calibrated and validated – validation against existing thermal plumes if possible, including the use of aerial or satellite imaging	Met – comprehensive validation reports provided
Model(s) to comply with Agency standards for hydrodynamic model calibration/validation	Met
Model(s) to be independently audited – audit report(s) to be provided	Met – Independent audit reviews of model performance provided
Model(s) to be available for use over period of at least 10 years from date of commissioning of the power station, and beyond that for as long as there is(are) no suitable alternative(s) available	Details to be agreed, but models have been setup on that assumption. Data outputs have been secured in long term secure archives and a regime is being developed to ensure that the models will continue to be fit for purpose over the timelines specified in the EA guidelines.
Agency will require access to the model(s) over the lifetime of the power stations	Details to be agreed, but will be met
Output to represent both absolute temperature and excess temperature above background, both in the near/mid-field and in the far-field	Met. Appropriate plume plots provided. Models can be interrogated to produce any required output at any location during the simulated year (2008).
Results to include the effects of tidal currents, residual currents, wind driven currents, turbidity, solar insolation, cloud cover, air temperature, surface cooling including the effect of wind, river flows, river temperature, thermal and saline stratification, seasonal effects (including short-term extreme temperature events), and sedimentation and erosion	Met. The 2 models have different algorithms for evaluating heat loss at the sea surface. The Delft3D model uses wind speed and direction and air temperature whereas the GETM model uses a full suite of meteorological parameters over an annual cycle obtained from a European hindcast meteorological model.
Results to cover a range of plausible scenarios of climate-change driven rises in air and sea temperatures and sea-levels over the planned life-time of the station	Met. The models have been subject to a range of plausible scenarios that are fully described in the modelling reports.
Results from alternative abstraction and discharge locations, including options to discharge near-bed, mid-water-column, or near-surface, and utilising	Met. Results from a full range of CW configuration options provided.

EA Requirement	Compliance Statement
different outfall designs, as appropriate	
Maps to show locations of designations, sensitive waters, relevant sensitive receptors, etc.	Met
Mixing Zones appropriate to the various thermal standards to be presented in 3-D, based on the statistics of the standard (e.g. annual average, maximum, 98%ile)	Met
Where a Mixing Zone relates to an instantaneous statistic (such as maximum value), then as far as is practicable, some indication of the variation of the duration of exceedence over the Mixing Zone	Met. Plume contour plots of annual maximum temperature and annual maximum and mean excess temperatures at the surface and the sea bed provided. Model outputs can be interrogated to provide any additional information upon request
In addition to the presentation of the overall Mixing Zones, various instantaneous representations of the temperature field are needed to enable an understanding of typical conditions	Met; such information is available at any location/ depth on request
Detailed impact assessment inside the Mixing Zones (and outside if considered appropriate) for all relevant receptors (flora and fauna throughout the water column, on and within the sea bed, and in the inter-tidal zone) to be assessed and discussed	Met
Relevant statistics of the mixing zones: e.g. area, volume, proportion of estuarine cross-section, proportion of time threshold value exceeded	Met
Post-scheme appraisal within 5 years of commissioning to validate (or not) the model predictions – based on field observations, satellite or aerial imaging, etc.	Details to be agreed, but will be met
If necessary, the re-calibration and validation of the model(s) following post-scheme appraisal.	Will be met if required

APPENDIX 18B: WATER FRAMEWORK ASSESSMENT

18B.1 Introduction to the Water Framework Directive Assessment

a) Introduction to the Hinkley Point C Project

18B.1.1 NNB Generation Company Limited (part of EDF Energy) is seeking a Development Consent Order (DCO) from the Infrastructure Planning Commission (IPC) to authorise the construction and operation of a new nuclear power station at Hinkley Point (hereafter referred to as Hinkley Point C). The development site is located on the west Somerset coast, 25 km to the east of Minehead and 12km to the north-west of Bridgwater (see **Figure 18B.1**). It is approximately centred on the National Grid Reference (NGR) 320300 145800.

18B.1.2 As well as the new nuclear power station at Hinkley Point, the project includes on-site and off-site associated developments that are proposed to facilitate the development and mitigate a range of potentially significant construction impacts on other environmental aspects, particularly related to traffic and socio-economics (taken together these developments are referred to as the 'Hinkley Point C Project'). The proposed off-site associated developments are located within or adjacent to Combwich, Cannington, Bridgwater and Williton (see **Figure 18B.2**). The on-site associated development includes accommodation for workers during the construction phase of the project. For a full description of the proposals, please refer to **Chapters 3**, **4** and **5**, of **Volumes 2** to **10** of the Environmental Statement (ES).

18B.1.3 The Hinkley Point C development site itself is located in the vicinity of the following Water Framework Directive (WFD) coastal and transitional water bodies (see Section 2):

- Bridgwater Bay; and
- Parrett Estuary.

18B.1.4 Water Framework Directive water bodies in the wider area are presented in **Figure 18B.3** in relation to the Hinkley Point C (HPC) development site. Given the location, nature and scale of the proposed new nuclear development, it is recognised that the proposals may have the potential to affect these water bodies and, therefore, the project needs to comply with measures set out within WFD (Ref. 1).

b) Preliminary Works for the Hinkley Point C Project

i Introduction

18B.1.5 EDF Energy's programme is for the new nuclear power station at Hinkley Point to commence operation by 2020. This timescale is in line with Government policy that encourages early development of new nuclear build to assist in meeting the UK's carbon reduction targets (to help mitigate climate change) and improve the diversity and security of our electricity supplies. In order to facilitate the commencement of operation by 2020, a number of enabling and preliminary works applications have been submitted by EDF Energy to prepare the development site for the new nuclear build. These applications are summarised in the following paragraphs.

ii Site Enabling Works

18B.1.6 A small package of enabling works on the development site is being initiated to facilitate proposed preliminary works (i.e. the site preparation works and temporary jetty). These enabling works include:

- remediation works to remove and reuse materials – including works to remove known areas of asbestos contamination – within a spoil mound and other areas of made ground located within the eastern part of the development site;
- construction of a bat barn to mitigate the impact of demolishing three existing barns (as part of the site preparation works and temporary jetty, see below) within the development site; and
- excavation of two temporary trenches for vibration testing and removal of topsoil for three temporary trial areas for compression testing within the development site.

iii Site Preparation Works

18B.1.7 The site preparation works are proposed by EDF Energy as preliminary works to the Hinkley Point C Project. The key features of the site preparation works are land clearance to remove existing structures and vegetation, earthworks to level the site and create development platforms, drainage works to manage surface water and groundwater that would be generated by dewatering deeper excavations during the earthworks, construction of internal haulage roads and site access points, and commencement of the mobilisation of the main civil works contractor that would be involved in subsequent stages of the construction of the nuclear power station, subject to the grant of a DCO for Hinkley Point C.

18B.1.8 An application for the site preparation works, accompanied by an ES, was made to West Somerset Council under the Town and Country Planning Act (TCPA) in November 2010 and Further Environmental Information was provided in April and July 2011. It should be noted that if a DCO is not granted for Hinkley Point C, then the site preparation works' proposal provides for the removal of all structures installed during the works and reinstatement of the application site.

iv Temporary Jetty

18B.1.9 A temporary jetty is also proposed by EDF Energy as preliminary works to the Hinkley Point C Project (see **Figure 18B.1**). The key features of the development include a jetty extending into Bridgwater Bay, an aggregates storage area, and a service road between the storage area and the existing access road to the Hinkley Point Power Station Complex. The jetty development would support the construction of Hinkley Point C by providing the infrastructure needed to import construction materials, especially bulk materials such as aggregate and cement, directly to site by sea, thus reducing Heavy Goods Vehicle movements on the public road network. It is expected that the jetty development would operate during the construction of Hinkley Point C up to the completion of the second reactor unit. At this point, the jetty would be dismantled and the site restored where it lies outside of the area of permanent works associated with the Hinkley Point C Project.

18B.1.10 EDF Energy applied for consent for the temporary jetty from the Marine Management Organisation (MMO) in December 2010 by way of a Harbour Empowerment Order (HEO) under the Harbours Act 1964 (as amended) and licences under the Food & Environment Protection Act 1985. Following consultation, an Addendum to the Temporary Jetty Development ES was submitted in June 2011. In addition, EDF Energy applied for the Transport and Works Act Order which was submitted to DECC and will allow EDF Energy to compulsorily acquire land required to construct the temporary jetty.

18B.1.11 It should be noted that if a DCO is not granted for Hinkley Point C, then the jetty development's proposal provides for the removal of all infrastructure in the water and on land, and reinstatement of the application site.

18B.1.12 The temporary jetty is also included within the application for Development Consent for Hinkley Point C in the event that the HEO application is unsuccessful. Hence, the temporary jetty's construction, operation, and dismantling and restoration phases are included in this WFD assessment.

c) Hinkley Point C Project

18B.1.13 Full details of the proposed development at Hinkley Point C are presented in **Chapter 2**, **Volume 2** of the ES, and will comprise a range of buildings above ground, sea bed and sub-surface structures and related facilities, including:

- two permanent Nuclear Islands housing the UK EPR reactor buildings and other essential buildings;
- two Conventional Islands incorporating the turbine halls and located adjacent to the Nuclear Islands;
- National Grid 400kV electricity substation to connect to the national grid electricity transmission system;
- an Operational Service Centre;
- a cooling water pumphouse for each UK EPR reactor unit with related infrastructure;
- cooling water intakes and outfall structures located on the sea bed, together with bored tunnels connecting these to the onshore cooling water infrastructure;
- a fish recovery and return system (FRR) comprising a sea bed outfall at the end of a bored tunnel;
- fuel and waste management facilities, transmission infrastructure, staff facilities, administration and storage;
- a Public Information Centre;
- a sea wall incorporating a public footpath;

- access and parking facilities for workers, visitors and deliveries for the main nuclear plant and the National Grid 400 kV substation; and
- landscaped areas (including ecological features and public rights of way (PRoW)).

18B.1.14 The built development will be distributed over a series of level platforms at various elevations. Elsewhere the permanent landform will be in accordance with the topography presented in the landscape restoration proposals.

18B.1.15 The main development platform will accommodate the Nuclear Islands, Conventional Islands, and onshore cooling water infrastructure. This platform will be at an elevation of 14 mAOD. This level has been determined on the basis that it meets safety case requirements which necessitate that the structures accommodated on the platform remain flood free during an extreme (1 in 10,000 year) tidal flood event. The platform elevation also reflects operational requirements and, in particular, the efficient functioning of the open circuit cooling system.

d) Associated Development

18B.1.16 EDF Energy has identified a number of associated developments that are considered necessary to facilitate the construction and, in some instances, the operation of Hinkley Point C and to mitigate potential environmental impacts associated with the project. Full details of the off-site associated developments are presented in **Chapter 2** in **Volumes 3** to **10** of the ES. In the absence of the proposed associated developments, the likely traffic and socio-economic impacts associated with the construction and operation of Hinkley Point C would be significantly greater in the local area. The proposed associated developments include:

- accommodation campuses for up to 1,510 construction workers on-site and in Bridgwater;
- park and ride facilities close to Junctions 23 and the Junction 24 (Somerfield) site close to the M5 motorway, Cannington and Williton;
- freight management facilities, courier consolidation facilities and an induction centre close to Junction 23 of the M5 motorway;
- freight management facilities close to Junction 24 of the M5 motorway (the Somerfield site);
- a bypass around the west of Cannington to minimise the amount of construction traffic using the local road network within the village; and
- refurbishment of the existing Combwich Wharf facility to accommodate the arrival of approximately 180 Abnormal Indivisible Loads and other construction related goods, over a period of approximately six years. A laydown area will also be provided adjacent to Combwich Wharf.

e) Information Available

18B.1.17 The Hinkley Point C Proposed New Nuclear Development DCO application is supported by a large number of documents. The ES to accompany the DCO application, which reports the outcomes of the Environmental Impact Assessment

(EIA) process, comprises 11 volumes providing an introduction and covering the main development, the off-site associated developments, and the cumulative impact assessment.

18B.1.18 In addition to the ES, a report to inform the Habitats Regulations Assessment (HRA) (Ref.18B.2) has also been produced and supports the DCO application. This report examines the effects of the proposed development on the Natura 2000 sites in and around the development sites and the Severn Estuary.

18B.1.19 Furthermore, a large number of surveys and research and assessment studies have been undertaken over a number of years, which provide supporting data and detail to the ES, the HRA and, therefore, to this document. Specifically, technical reports written by the BEEMS project (British EDF Estuarine and Marine Studies) TR184 (Ref. 18B.3), TR186 (Ref. 18B.4), TR163 (Ref. 18B.5), TR197 (Ref. 18B.6) and TR148 (Ref. 18B.7) have been used.

18B.2 The Water Framework Directive Assessment Process

a) Introduction

18B.2.1 In December 2003, the WFD was transposed into national law by means of the Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (Ref. 18B.1. These Regulations provide for the implementation of the WFD from designation of all surface waters (rivers, lakes, transitional (estuarine) and coastal waters, as well as ground waters) as water bodies to achieving good ecological status by 2015. The Environment Agency is the competent authority for implementation of the WFD.

18B.2.2 Unlike the EU Birds and Habitats Directives (EC Directive on the Conservation of Wild Birds 2009/147/EC and EC Directive on the Conservation of Natural Habitats and of Wild Fauna and Flora 92/43/EEC, respectively), which apply only to designated sites, the WFD applies to all water bodies, including those that are man-made. The consideration of the proposals under the WFD will, therefore, apply to water bodies that have the potential to be impacted by the Hinkley Point C Project proposals.

18B.2.3 Classification schemes for both estuarine and coastal waters out to one nautical mile have been developed in response to WFD. The scheme classifies the status of Transitional and Coastal Waters (TRaC) using information on the ecological, chemical and hydromorphological quality of a body of water. For surface waters there are two separate classifications for water bodies: ecological and chemical. For a water body to be in overall ‘good’ status, both ecological and chemical status must be at least ‘good’.

18B.2.4 Ecological classification comprises:

- the condition of biological elements, for example fish;
- concentrations of supporting physico-chemical elements, for example the oxygen or ammonia levels;
- concentrations of specific pollutants, for example copper; and
- largely undisturbed hydromorphology for high status.

18B.2.5 Ecological status is recorded on the scale of high, good, moderate, poor or bad. 'High' denotes largely undisturbed conditions and the other classes represent increasing deviation from this natural condition, otherwise described as a 'reference condition'. The ecological status classification for the water body, and the confidence in this, is determined from the worst scoring quality element.

18B.2.6 Chemical status is assessed by compliance with environmental standards for chemicals that are listed in the EC Environmental Quality Standards Directive 2008/105/EC1. These chemicals include priority substances, priority hazardous substances, and eight other pollutants carried over from the Dangerous Substance Daughter Directives. Chemical status is recorded as 'good' or 'fail'. The chemical status classification for the water body is determined by the worst scoring chemical.

18B.2.7 For TRaC water bodies that have been designated as heavily modified (HMWB), the Environment Agency must classify according to their ecological potential rather than status. UKTAG have adopted the 'mitigation measures approach' for classifying HMWBs (Ref. 18B.8).

18B.2.8 This approach first assesses whether actions to mitigate the impact of physical modification are in place to the extent that could reasonably be expected. If this mitigation is in place, then the water body may be classified as achieving 'good' or better ecological potential. If this level of mitigation is not in place, then the water body will be classed as 'moderate' or worse ecological potential.

18B.2.9 Before an overall ecological potential classification is applied, the second step is for the results of the mitigation measures assessment to be cross-checked with data from biological and physico-chemical assessments.

18B.2.10 Where the Environment Agency has data for biological quality elements that show signs of damage from pressures other than hydromorphological alterations, for example, if the diatom or phytoplankton status is poor because of nutrient pressures, the ecological potential will be changed. To reflect this other pressure the water body will be labelled as 'Poor Ecological Potential'. This is also true where data are available for physico-chemical quality elements.

18B.2.11 Some areas require special protection under European legislation. WFD therefore brings together the planning processes of a range of other European Directives such as the revised Bathing Waters Directive (2006/44/EC) and the Habitats Directive. These Directives establish protected areas to manage water, nutrients, chemicals, economically significant species and wildlife – and have been brought in line with the planning timescales of WFD.

b) Procedure and Process

18B.2.12 There is no designated methodology for the assessment of plans or projects in relation to undertaking WFD assessments. There are, however, several sets of guidance that have developed in relation to undertaking such assessments, predominantly written by the Environment Agency. Considered to be the most relevant to the Hinkley Point C Project proposals is the document "Clearing the Waters" (Ref. 18B.9), which has been produced by the Environment Agency in order to assist in the assessment of the potential impact of dredging and disposal on the requirements of the WFD. This document recommends a four stage process. In order to provide a general methodology for undertaking this assessment, the descriptions have been altered to provide context for the activities associated with the Hinkley Point C Project, as follows:

- **The Screening Stage (Stage 1)**: This stage only applies to pre-existing activities. In this context this means activities which started or were ongoing during the period 2006-2008. New projects, that is, ones commencing after the 1st January 2009 should go straight to the scoping stage (i.e. Stage 2). However, initial screening information is necessary as part of the scoping stage and, therefore, this stage is still often completed in practice in order to inform Stage 2.
- **The Scoping Process (Stage 2)**: The scoping stage enables regulators and operators to determine the scope of the assessment required to establish whether an activity will have a non-temporary effect on water status at water body level. Scoping therefore assists in defining which WFD parameters could be affected and in agreeing an appropriate level of assessment to meet WFD requirements.
- **Assessment (Stage 3)**: This stage of the assessment aims to assess whether the activity will have a significant non-temporary effect on the status of one or more WFD parameters at water body level. The test is therefore to determine whether the activity is likely to affect a parameter sufficiently to lower its existing class status. For priority substances, the process requires the assessment to consider whether the activity is likely to cause the parameter to achieve good chemical status.
- **Identification and Evaluation of Measures (Stage 4)**: If it is established that an activity is likely to affect water status at water body level (that is, by causing deterioration or by preventing achievement of the WFD objective), or that an opportunity may exist to contribute to improving status at a water body level, potential measures to achieve either of these must be investigated. This stage considers these measures and, where necessary, evaluates the measures in terms of cost and whether it is disproportionate.

c) Consultation on the WFD Assessment

18B.2.13 Significant consultation with the regulators on both the Environmental Impact Assessment (EIA) (and in particular the Marine Water and Sediment Quality Chapter, **Volume 2 Chapter 18**) and the HRA has highlighted areas of concern relevant to this assessment and has been used to inform it. This consultation is detailed in **Chapters 17**, **18** and **19**, in **Volume 2** of the ES, and **Chapter 2** of the HRA Report.

18B.3 The WFD assessment: Stage 1

a) Stage 1: Background

18B.3.1 Although Stage 1 is not strictly required in this case because the proposed development is a new project, basic information is required in order to progress the assessment forward. This information falls into two groups. The first group contains information in relation to the proposed activities. The second contains information in relation to the water bodies that the activities could affect.

18B.3.2 In order to scope the assessment for the activities set out below, tables provided in the Clearing the Waters guidance (Ref.18B.9) have been modified in order to assist in informing the scoping assessment and to provide a summary of the screening assessment.

18B.3.3 To determine which activities are of relevance to the WFD assessment, all potential impacts on marine water quality and marine ecology need to be considered. The following bullet points summarise the potential impacts identified during each of the relevant project phases: construction, commissioning and operation. Decommissioning impacts are not considered as the outcome in the ES for all parameters determines that decommissioning impacts are likely to be less or similar to those identified in the construction and operational phases.

18B.3.4 The elements of the development during the Hinkley Point C construction phase that could lead to marine water quality or marine ecology being affected are:

- surface drainage and groundwater discharges to the foreshore;
- construction of the construction outfall;
- construction, operation and dismantling of the temporary jetty;
- refurbishment of Combwich Wharf;
- treated sewage effluent from the temporary sewage works;
- drilling of the cooling water tunnel and the Fish Recovery and Return (FRR) system, and the installation of cooling system head structures;
- construction of the sea wall; and
- accidental spillages.

18B.3.5 The elements of the development during the commissioning phase that could lead to marine water quality and marine ecology being affected are the:

- surface drainage and groundwater discharges to the foreshore (until the cooling water system becomes available, which would then become the route of discharge);
- treated sewage effluent the from temporary sewage works (until the permanent treatment works are in place and the cooling water system is made available, which would then become the route of discharge); and
- discharge of commissioning test waters (to the foreshore for ‘cold’ tests, and to the subtidal via the cooling water outfall, once available, for ‘hot’ tests).

18B.3.6 The elements of the development during the operational phase that could lead to marine water quality and marine ecology being affected are the:

- groundwater discharge to the foreshore via the percolated sea wall drainage system;
- surface drainage and groundwater discharges via the cooling water tunnel;
- treated sewage effluent, from an on-site sewage treatment works, via the cooling water tunnel; and

- intake and discharge of the operational cooling water (including operational chemical contributions) to the Bristol Channel.

18B.3.7 For the purposes of this assessment, it is assumed that the bulk of the sediments that will be removed from any dredging works will be either deposited locally or re-suspended within the Severn Estuary (if the relevant Marine Licence criteria are met). There is, however, the possibility that any materials not deemed suitable for disposal in this way will be taken to an existing licensed disposal site, probably the Cardiff Grounds. Since the DCO application does not include for activities that will be undertaken under a Marine Licence (such as the dredging and disposal), a separate WFD assessment will be undertaken at such time as the Marine Licence applications are submitted. However, any resulting impacts from increased suspended sediment mobilisation during to the dredging are considered for each relevant activity herein.

b) Stage 1: Screening

18B.3.8 As described in Section 1.5 above, a full EIA has been completed for the proposals and submitted with the DCO application for the Hinkley Point C Project. The information in the following section draws on the impact assessment and conclusions provided within the ES, particularly **Volumes 2** to **11**. **Table 18B.1** lists all potential impacts on marine waters and summaries where potential impacts in relation to WFD chemical, ecological and hydromorphological status could occur.

c) Water Body Status

18B.3.9 The waters around the mouth of the River Parrett to the east of Hinkley Point are defined as a HMWB and are characterised as having moderate ecological potential. The water between the west of Hinkley Point and Porlock Bay is the Bridgwater Bay water body and is characterised as having moderate ecological status (Ref. 18B.10). **Table 18B.2** summarises the information available for each of these water bodies.

Table 18B.1: Details of Scheme Activities and Summary of Potential to Impact on General WFD Parameters

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Construction							
Construction, operation and removal of temporary jetty (not dredging)	Bridgwater Bay	Due to the way in which the jetty will be constructed (piled with open structure) only short term localised impacts on marine water quality from suspended sediments are predicted during construction. In terms of surface water, control measures will be put in place to ensure minimal spillage during loading and unloading. Run-off will therefore be limited to surface water and potentially any hydrocarbon residue. The small surface area of the jetty would limit the amount of run-off and effects are unlikely to be significant.	Due to the open pile nature of the jetty and the application of soft start piling techniques, no long term effects on fish are predicted. Impacts on benthic invertebrates and other supporting habitats are not deemed to be potentially significant effects within the ES. The exception is *Corallina*; however here only small areas of habitat in the vicinity are likely to be impacted and therefore minor impacts are predicted. As a result are not deemed significant on a water body scale (see Section 19.6, **Volume 2** of the ES).	Effects during construction are likely to be localised and transient and, thus, small scale in magnitude. It is considered that Hinkley Point C construction would cause very limited change to hydrodynamic and sedimentary properties.	No	N/A	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Dredging for temporary jetty berth (both capital and maintenance)	Bridgwater Bay and Parrett Estuary	Potential for contaminated sediments to impact on water quality and therefore cause EQS exceedence, i.e. Cefas Action Level 1 is predicted to be exceeded for some parameters (see Section 18.6, **Volume 2** of the ES). This is a trigger for assessment as detailed in Ref. 18B.9	Potential for EQS exceedence to impact on marine ecological status via toxicological effects. Impacts in relation to smothering are not deemed to be significant as it is expected that the receptor would experience little or no degradation because sediment deposition is likely to be within the range currently experienced in the study area (see Section 19.6, **Volume 2** of the ES).	Given the hyper-tidal nature of the water bodies and the associated extreme turbidity regime present, the sediment plume would become subject to the tidally driven transport, deposition and resuspension processes, and thus be continuously reworked (see Section 18.6, **Volume 2** of the ES). Given the relatively small volume involved, it is not considered likely that the local or wider deposition of sediment from the plume would have any significant effect on existing bathymetry, transport processes or depositional bedforms (see Section 17.6, **Volume 2** of the ES).	Maintenance dredging ongoing and, therefore, periodic effect over timescale of the jetty (7-9 years).	No	Yes

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Construction of structures and discharge of surface drainage and sewage effluent discharges to the foreshore	Bridgwater Bay	There is the potential for impact on marine water quality. However control measures and treatment would be installed to ensure environmental impacts are kept to a minimum. Additionally, any impact would only occur during construction, as during the operational phase all discharges wouldl be made via the cooling water outfall (see Section 18.6, **Volume 2** of the ES). Impacts are assessed as being minor.	As impacts on water quality are deemed to be unlikely, it is not anticipated that significant marine ecological impacts are likely. Additionally, outfalls have been located in order to avoid sensitive intertidal habitats such as *Corallina* (see Section 19.6, **Volume 2** of the ES).	Structures will be constructed above high tide and therefore hydromorphological impacts are deemed unlikely.	No	N/A	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Construction of seawall	Bridgwater Bay	As the majority of the works for the seawall would be undertaken above high water, the potential for impact on water quality is low. Discharge would relate to surface water run-off with limited potential for contaminants, and would be monitored and treated if required (see Section 16.6 and **18.6**, **Volume 2** of the ES)	The main biotope present within the working area is barren littoral shingle. All other biotopes are found on the lower shore are typical of relatively sheltered estuarine littoral environments and are widespread in the immediate vicinity of Hinkley Point, and limited localised effects are predicted as a result of disturbance or discharges (see Section 19.6, **Volume 2** of the ES).	As the majority of the works for the seawall would be undertaken above high water, the potential for impact on hydromorphology is limited (see Section 17.6, **Volume 2** of the ES).	No	N/A	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Drilling of cooling water and FRR tunnels, and installation of cooling water intake and outfall structures	Bridgwater Bay	There is the potential for impact on marine water quality but this is likely to be minimal and would only be for a short period during which the construction is occurring. Treatment of tunnel drilling wastewater would be provided should mud-assisted drilling be necessary to allow the discharge to be made to the foreshore (see Section 18.6, **Volume 2** of the ES).	The benthos of this area is typical of the extensive muddy plain that makes up most of the local seabed. Habitats of interest such as *Sabellaria* are not present within the proposed sites. Thus, no significant impacts are therefore predicted (see Section 19.6, **Volume 2** of the ES).	Effects are likely to be localised and transient, and thus be of small magnitude. It is considered that Hinkley Point C construction would cause very limited change to hydrodynamic and sedimentary properties.	No	N/A	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Refurbishment and extension of Combwich Wharf (not dredging)	Parrett Estuary	Due to way in which the wharf would be refurbished (piled and then in-filled around the existing structure) only short term, localised impacts on marine water quality from resuspended sediment are predicted during construction. In terms of surface water, control measures would be put in place to ensure minimal spillages occur during loading and unloading of vessels and goods. Run-off would be limited to surface water and potentially any hydrocarbon residue. The small surface area of the wharf would limit the amount of run-off and, therefore, effects are unlikely to be significant (see Section 18.6, **Volume 7** of the ES).	Due to the estuarine location of the piling and the application of soft start piling techniques during periods when areas are inundated by the tide, no medium or long-term effects on fish are predicted. Impacts on benthic invertebrates and other supporting habitats are not deemed to be potentially significant within the ES due to the limited estuarine area affected (see Section 18.6, **Volume 7** of the ES).	The wharf refurbishment would largely replace an existing structure and, therefore, the footprint would be similar to that already existing (see Section 18.6, **Volume 7** of the ES).	No	No – see hydromorphologic al assessment	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Dredging of Combwich Wharf Berth (both capital and maintenance)	Parrett Estuary	There is the potential for contaminated sediments to impact on water quality and therefore cause EQS exceedence, i.e. Cefas Action Level 1 is exceeded for some parameters (see Section 18.6, **Volume 7** of the ES). This is a trigger for further assessment (see Ref. 18B.9).	If EQS are exceeded there is the potential for impacts on marine ecological status via toxicological effects. Impacts in relation to smothering are not deemed to be significant as it is expected that the receptor would experience little or no degradation because sediment deposition is likely to be within the range currently experienced in the study area (see Section 18.6, **Volume 7** of the ES).	Given the tidal nature of the estuary water body and the associated extreme turbidity regime present, the sediment plume would become subject to the tidally driven transport, deposition and resuspension processes, and thus be continuously reworked. Given the relatively small volume involved, it is not considered likely that the local or wider deposition of sediment from the plume would have any significant effect on existing bathymetry, transport processes or depositional bedforms (see Section 18.6, **Volume 7** of the ES).	Maintenance dredging would be ongoing and, therefore, have a periodic effect over timescale of the Wharf operation (c. 60 years).	No	Yes

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Commissioning							
Discharge of hot and cold commissioning test water	Bridgwater Bay	Work in the EIA indicates that where required, all parameters likely to be present in the cold and hot test water would be subject to on-site treatment, in order to meet EQS. As a result, significant impacts are deemed unlikely (see Section 18.6, **Volume 2** of the ES).	As discharges will be treated to meet EQS and therefore significant impacts are not predicted	During the commissioning process the volumes of water are insignificant in relation to the water body (less than 0.1% of total volume at low water), and the volumes of water abstracted would be discharged with only a temporary interval. These limited effects which would be mostly confined to offshore locations would not result in localised or general changes to hydromorphology. The exception are the cold water tests which will discharge to the foreshore, however, the short term nature of the tests and the flows are unlikely to result in any changes to hydromorphology.	No	No	No

Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Operation							
Intake and discharge of cooling water	Bridgwater Bay and Parrett Estuary	There is the potential for EQS exceedences associated with chemicals discharged within cooling water (see Section 18.6, **Volume 2** of the ES). Potential for thermal effects (see Section 18.6 **Volume 2** of the ES)	Potential for EQS exceedence to impact on marine ecological status via toxicological effects. Potential entrainment and impingement of fish and plankton via intake structure. Impacts in relation to thermal barriers effects on fish migration have been modelled and conclude that barriers would not be present (see Section 19.6, **Volume 2** of the ES).	Whilst the power station is operating, precisely the same volume would be discharged as abstracted. No suspended solids would be removed. There would thus be no impact upon the tidal prism of the Inner Bristol Channel and no loss of sediment from the system as a result of this process (see Section 17.6, **Volume 2** of the ES).	Intake and discharge would occur for 60 years, therefore, there is the potential for a non-temporary effect.	No	Yes
Presence of marine infrastructure (cooling water intake, outfall, FRR and seawall)	Bridgwater Bay	Insignificant impacts are predicted in relation to marine water quality due to the presence or maintenance of the structures (i.e dredging) (see Section 18.6, **Volume 2** of the ES).	The footprint of the structures could impact on marine invertebrates through loss of habitat. However, only very small areas of the seabed would be impacted by the development, therefore no significant impact is predicted on the marine ecological status (see Section 19.6, **Volume 2** of the ES).	Minimal impacts on hydromorphology predicted as the sub-tidal structures would only result in localised scour which occurs throughout the sub-tidal environment, with no morphological changes noticeable at the water body scale (see Section 17.6, **Volume 2** of the ES).	No	No	No

Hinkley Point C activity	Water body potentially impacted	Potential impact on chemical status	Potential impact on marine ecological status	Potential impact on hydromorphological elements	Non-temporary effect?	Will any of the water body mitigation measures be adversely impacted?	Assessment to Stage 2?
Presence of seawall	Bridgwater Bay	Insignificant impacts are predicted in relation to marine water quality due to the presence of the seawall.	The footprint of the seawall could impact on marine invertebrates through loss of habitat. However, only very small areas of the upper shore would be affected which comprises barren littoral shingle and, therefore, no effect on marine ecological function or status is predicted (see Section 19.6, Volume 2 of the ES).	As both the current cliff and the proposed sea wall stand on the upper shore well above mean high tides, only in extreme conditions will be any hydrodynamic interaction. The seawall therefore replaces the existing upper shore boundary with a similar plan form and steepness; therefore there would be no effect on hydromorphological parameters (see Section 17.6, **Volume 2** of the ES).	No	No	No
Other discharges (such as sewage effluent, groundwater and surface water) via the cooling water outfall	Bridgwater Bay and Parrett Estuary	Taken into account in assessments provided for cooling water outfall calculations. Parrett Estuary	7069.01ha	Transitional	HMWB – Flood protection	Moderate ecological potential Good chemical status	Good ecological potential by 2027 High chemical Status by 2015	Dissolved inorganic Nitrogen	Yes: Structures or other mechanisms in place and managed to enable fish access to waters

18B.3.10 Protected areas within each of the water bodies are summarised in **Table 18B.3**.

Table 18B.3: Details of Protected Areas within the WFD Water Bodies

Water Body name and reference	Protected areas
Bridgwater Bay	Freshwater Fish Directive, Habitats and Species Directive, Nitrates Directive, Conservation of wild birds directive
Parrett Estuary	Bathing Waters Directive, Freshwater Fish Directive, Nitrates Directive, Conservation of Wild Birds Directive, Urban Wastewater Treatment Directive

18B.3.11 It should be noted that impacts in relation to Protected Areas, such designated habitats, are considered separately within the ES (Section 18.6, **Volume 2** of the ES) and the in HRA Report. Full assessment is not, therefore, provided here. Impacts on designated Bathing Waters were screened out on the basis that the plume does not extend to these designations and, therefore, impacts are not predicted. In terms of the nitrates and urban wastewater directive, consideration of the potential for discharge of nitrogen has been considered and is summarised in Section 18B.5.

18B.3.12 For each activity identified as potentially having a non-temporary effect on marine waters or marine ecology, tables similar to those presented in the Environment Agency's document Clearing the Waters in relation to screening (Ref. 18B.9) have been completed (see **Table 18B.4** to **Table 18B.5**).

18B.4 Stage 2: The Scoping Stage

a) Introduction

18B.4.1 The scoping stage requires the identification of all WFD parameters that potentially could be affected at water body level by the proposed activity. The guidance **Plate 18B.1**.

Plate 18B.1: The eight stage process required in order to scope WFD assessments

Step 1	**Identify issues**
Step 2	Record current status and 2015 objective of the water body(s)
Step 3	Indicate likelihood of non-temporary effect on status at water body level
Step 4	Indicate data availability
Step 5	Decide on the level of the assessment
Step 6	For water bodies not at “good status” identify all failing WFD parameters
Step 7	Consider the delivery options for the assessment
Step 8	Confirm and agree the scope/delivery mechanism with the regulator/decision maker and/or us
Proceed if necessary to assessment stage	

b) Steps 1, 2 and 3

18B.4.2 Step 1 of the scoping stage involves considering each WFD parameter on the list in the WFD assessment tables to identify all those parameters where a possible casual link exists for all activities screened in during Stage 1. Step 2 records the current status and the 2015 objective of the quality element. A level of confidence in the assessment must also be identified at this stage where this is possible.

18B.4.3 Step 3 of the scoping phase then requires a preliminary judgement to be made on how likely it is that the activity could have a non-temporary effect on status at water body level. Such an effect could involve a deterioration in status. Alternatively, it could also mean that the activity could prevent the water body(s) from meeting WFD objectives (i.e. good status or good ecological potential). This element of the assessment has been completed in Section 3 (above) and, therefore, reference is made to **Table 18B.4** to **Table 18B.6**.

c) Steps 4, 5 and 6

18B.4.4 Steps 4, 5 and 6 consider the availability of data for each activity identified in Steps 1 to 3, and Steps 5 and 6 provide for considering the level of assessment required and the identification of all failing WFD parameters.

d) Steps 7 and 8

18B.4.5 Step 7 requires the consideration of the delivery of the assessment and Step 8 requires the confirmation and agreement of the scope of the assessment with the regulator.

18B.4.6 In this case it is considered that all of these steps have been completed within the screening exercise and therefore the three activities identified at the screening stage are carried through into Stage 3: Assessment.

18B.5 Stage 3: Assessment

a) Introduction

18B.5.1 An assessment of effects under the WFD must focus on the potential for impacts on the status of the various WFD parameters and should only consider whether the activity will have a significant non-temporary effect on the status of one or more WFD parameters at water body level (Ref.18B.9). The WFD 'test' is, therefore, about determining whether the activity is likely to affect a parameter sufficiently to lower its existing class status. The assessment again is undertaken in a staged process similar to that required in undertaking EIA:

- Step 1: consultation and further elaboration of scope with regulators and key stakeholders;
- Step 2: data collection/collation;
- Step 3: baseline environment description (for the parameters scoped into the assessment);
- Step 4: identification of how the proposed activity may affect the baseline environment (what type of changes may occur);
- Step 5: qualitative/quantitative description of the predicted changes including the area affected and the duration of the change;
- Step 6: impact assessment (the significance of the predicted change against the relevant standards and thresholds); and
- Step 7: discussion (including levels of confidence and certainty).

18B.5.2 Section 1.5 provides information on the consultation undertaken to date. For the purposes of this stage of the assessment, steps 2 and 3 have been combined to provide the baseline descriptions in Section 5.3.

b) Data Collation/Collection

18B.5.3 See Section 1.5

c) Baseline

18B.5.4 Full baseline conditions are provided in **Chapters 18** and **19**, **Volume 2** of the ES for marine water quality and marine ecology respectively and therefore further information is not presented here.

d) WFD Impact Assessment

i Impacts on WFD Water Bodies Associated with Dredging at the Temporary Jetty

18B.5.5 Due to the relatively small areas to be dredged (in relation to the scale of the Bristol Channel and water bodies), and the high concentrations of naturally occurring suspended solids in the area, modelling of potential impacts from suspended sediment plumes was not considered to be necessary. Additionally, any sediment suspended within the water column would be quickly dispersed into existing sediment transport processes. Impacts on transparency and oxygen levels were therefore deemed unlikely (Section 18.6, **Volume 2** of the ES).

18B.5.6 Dredging activities have the potential to increase water contaminant concentrations through sea bed disturbance. Comparison of the survey data collected in 2009 with Cefas Action Levels (Ref. 18B.1112) found elevated metal concentrations to be widespread but very few of the metal concentrations recorded are considered to be highly contaminated. Metal concentrations were routinely found that were above Cefas Action Level 1 and hence further assessment in relation to WFD compliance is required.

18B.5.7 In order to identify whether dredging in this area could potentially impact on chemical status, a site-specific assessment in order to determine whether sediment-bound contaminants could be mobilised and impact marine water quality status undertaken as part of the EIA is relevant here. Further details are provided within **Chapter 18**, **Volume 2** of the ES.

18B.5.8 In summary the method:

- estimated the maximum increase in suspended solids concentration as a result of dredging activities;
- multiplied the maximum contaminant concentration recorded in sediment cores with the estimated concentration increase to give a concentration of pollutant released into the water column;
- used partition coefficients to estimate the concentration of pollutant that is likely to enter the dissolved phase; and
- compared estimated maximum values of dissolved contaminant with WFD marine water EQSs.

18B.5.9 **Table 18B.7** presents the calculated maximum concentrations of metals entering the water column from disturbed sediment, and compares the resulting dissolved contaminant concentrations with marine water WFD EQS.

Table 18B.7: Estimated maximum concentrations of metals entering the water column and the dissolved phase from disturbance as a result of marine sediment dredging

Determinand	Max overall conc. ($mg.kg^{-1}$)[1]	Total conc. in suspen. ($mg.l^{-1}$)[2]	Total conc. in susp. ($\mu g.l^{-1}$)	Partition Coeff. [3]	Conc. entering diss. phase ($\mu g.l^{-1}$)	Backgnd mean conc ($\mu g.l^{-1}$)[4]	Total diss conc ($\mu g.l^{-1}$)[5]	WFD Marine EQS
Arsenic	30	0.015	15	10000	1.50E-03	2.3	2.3015	25 [AD]
Cadmium	1.5	0.00075	0.75	130000	5.77E-06	<0.01	<0.01	0.2[AD]
Chromium	67	0.0335	33.5	191000	1.75E-04	0.02	0.0202	0.6 [AD*]
Copper	51	0.0255	25.5	61000	4.18E-04	3.95	3.9504	5 [AD]
Lead	141	0.0705	70.5	882000	7.99E-05	0.02	0.02	N/A
Mercury	0.67	0.000335	0.335	100000	3.35E-06	0.02	0.02	0.07 [AD]
Nickel	59	0.0295	29.5	80000	3.69E-04	0.19	0.1904	20 [AD]
Zinc	307	0.1535	153.5	4860	3.16E-02	39.27	39.302	40 [AD]

Notes:
A = Average; D = Dissolved; * = chromium VI;

18B.5.10 After the application of partition coefficients, the predicted concentrations of metal contaminants entering the dissolved phase are several orders of magnitude below the EQS set by the WFD and Dangerous Substances Directive. A deterioration in chemical water quality status is not, therefore, predicted.

18B.5.11 In terms of biological parameters, potential impacts identified include those on fish and marine invertebrates. The invertebrate biotopes within the marine sediments potentially affected by the berthing pocket during the EIA were deemed to be typical of the extensive muddy plain that makes up most of the local seabed (Section 19.5, **Volume 2** of the ES). Additionally, the small area over which the dredging is likely to occur (approx 8000 m^2) is relatively small in relation to the size of the water body. Re-colonisation is also likely to occur once is dredging complete and any additional disturbance ceases. Impacts in relation to marine invertebrates are therefore deemed unlikely to effect ecological status.

18B.5.12 In terms of fish, it is considered that migratory fish are most at risk as they could be present in the study area during certain times of year and / or intermittently; consequently they could be affected by physical disturbance associated with the dredging. However, migratory fish would be able to avoid areas of physical disturbance and only a very small percentage of the subtidal habitat of the water body would be affected at any one time. Impacts on fish are therefore unlikely to effect ecological status.

ii Impacts Associated with Dredging at Combwich Wharf

18B.5.13 The refurbishment of Combwich Wharf will involve a range of construction and operational activities that could lead to disturbance of estuarine silts and sediments within the tidal River Parrett over and above those already experienced during the day to day operation of Combwich Wharf. Such activities include further dredging; removal of existing wharf infrastructure; and a range of piling activities. It is estimated that refurbishment of Combwich Wharf will require the dredging of approximately 5,000 m^3 of bank materials and sediment. Maintenance dredging may also be required during the operation of the Wharf. It should be noted, however, that removal of sediment during the construction will predominantly undertaken using land-based plant operating at low water and transported away by land. Impacts in relation to dredging therefore relate, in the main, to any maintenance dredging required.

18B.5.14 Sampling of the sediments in the location of works indicated generally low levels of contamination throughout the depths of the cores. There are occasional exceedances of Cefas Action Level 1 for individual contaminants but no exceedances of Cefas Action Level 2 were recorded (Ref. 18B.1).

18B.5.15 Sediment disturbance during the construction works is therefore unlikely to lead to the release of contaminants into the water column at concentrations that would result in an adverse effect on water quality (Ref. 18B.13). It is the case that sediment released during the works and during operation would be rapidly entrained into the transport system and either re-deposited within the River Parrett or flushed out into the wider Bridgwater Bay. As such, significant dilution would occur, resulting in the redistribution of any contaminants at concentrations that would not exceed background levels elsewhere in the system. The water quality of the water body is therefore unlikely to be affected.

iii Impacts Associated with the Discharge of Cooling Water (Thermal Impacts)

18B.5.16 Full details of the characteristics of the cooling water discharge are included in Section 18.6, **Volume 2** of the ES and it is determined that under normal operating conditions, the HPC EPRs' water would be discharged up to 12.5°C above ambient temperature. To ensure that all transitional and coastal waters are at least at good status by 2015, UKTAG 2008 (Ref. 18B.14) has produced draft thermal standards for rivers which, in the absence of any other standards, are being used for TraC waters until such time as standards specific to TraC waters are determined.

18B.5.17 UKTAG 2008 (Ref. 18B.14) states that in order to achieve WFD good status, maximum temperatures at the edge of the mixing zone (as thermal impacts are largely related to point discharges) must not exceed 23°C, based on an annual 98 percentile, and that outside the mixing zone temperatures should not rise by more that 3°C.

18B.5.18 On the basis of these standards, it is considered that a 2.6°C mean temperature increase above an assumed 98 percentile of 20.4°C (baseline data as determined in Section 18.5, **Volume 2** of the ES) would exceed the 23°C temperature boundary for good/moderate status in terms of temperature and, therefore, cause a water body deterioration to moderate status.

18B.5.19 In order to assess the potential for deterioration, plume modelling was undertaken. For full details of this modelling, please refer to Section 18.4, **Volume 2** of the ES and Technical Report 186 by BEEMS (Ref. 18B.4). Using the model runs as described in Section 18.4, **Volume 2** of the ES, the three relevant scenarios for the consideration of potential impacts are runs C, D and E. These correspond to Hinkley Point C operating in isolation at 100% output (run C), Hinkley Point C operating at 100% output simultaneously with Hinkley Point B operating at 70% (run D) and Hinkley Point C operating at 100% simultaneously with Hinkley Point B at 100% (run E), respectively:

- Run C calculates the thermal plume conditions in relation to the operation of Hinkley Point C only (i.e. the effects of Hinkley Point B are removed). This reflects conditions that would occur in the future when Hinkley Point B ceases generation.
- Run D reflects a time whereby Hinkley Point C is operating at full capacity and Hinkley Point B is operating, but potentially below consented maxima (as described above). Run D thus provides the opportunity to assess impacts on the potential lower range of Hinkley Point B operation.
- Run E is considered to represent the upper limit of potential combined operation, i.e. both Hinkley Point C and Hinkley Point B are operating at maximum consented levels.

18B.5.20 For the purposes of this assessment, run E represents the worst-case scenario, i.e. with both power stations operating in combination at maximum consented levels.

18B.5.21 **Figures 18B.4**, **18B.5 and 18B.6** show the modelled mixing zone in relation to standards for Runs C, D and E at the surface and seabed for both standards.

Table 18B.8 summaries the mixing zones in terms of area of the surface and seabed affected by the discharge of cooling water for each of the runs.

Table 18B.8: Prediction of thermal plume areas exceeding WFD thermal standards

Run		Area of plume >23°C (hectares)		Area of plume >3°C (hectares)	
		Parrett Estuary	Bridgwater Bay	Parrett Estuary	Bridgwater Bay
C	Surface	0	38 (0.4%)	0	9 (0.1%)
	Sea bed	0	2 (0.02%)	0	0.4 (<0.01%)
D	Surface	812 (11%)	246 (3%)	385 (5%)	41
	Sea bed	879 (12%)	57 (0.6%)	384 (5%)	6 (0.1%)
E	Surface	1023 (14%)	401 (4%)	692 (10%)	147 (1.6%)
	Sea bed	1062 (15%)	163 (2%)	764 (11%)	42 (0.5%)

18B.5.22 On the basis of this information, it can be concluded that only the Bridgwater Bay water body would be impacted by the discharge of Hinkley Point C alone and this is equivalent to an impact of less than 0.5% of the water body area. A deterioration in class status is therefore unlikely to occur for the operation of Hinkley Point C alone in either water body.

18B.5.23 When considering the potential operation of Hinkley Point C and Hinkley Point B together at 100%, the zone of impact largely relates to the Parrett Estuary water body where up to 15% of the seabed could be impacted by a change in temperature of over 23°C. There could, therefore, be a potential deterioration in status within the Parrett Estuary water body. It is therefore is considered appropriate to consider the potential impact of these thermal changes on the biological parameters as set out in **Table 18B.3**.

18B.5.24 The identified elements in the ES (Section 19.6, **Volume 2**) that potentially could be impacted by thermal changes are marine invertebrates and fish. It is important to note that whilst the combined modelling work demonstrates that compared to the discharge of Hinkley Point C alone, larger areas of the Parrett Estuary water body would be affected by raised water temperatures with Hinkley Point C and Hinkley Point B operating simultaneously, in reality the ecological effects of the combined discharges would be relatively limited. This is because any temperature effects of the discharge from Hinkley Point B are already present in the system as Hinkley Point B is currently operating and, therefore, represents reference or baseline conditions to some extent.

18B.5.25 The potential impact on the benthic invertebrates is, therefore, considered to be whether the additional increase in water temperature associated with Hinkley Point C would combine with the existing discharge from Hinkley Point B to increase water temperatures in the area already affected by Hinkley Point B such that any further effects on the ecology might be expected. In respect of this, the only identified benthic invertebrate receptor likely to be sensitive to an increase in temperature is *M. balthica*. All other epibenthic and infaunal species are deemed unlikely to be negatively impacted by the combined temperature effect of the discharge plumes (Section 19.6, **Volume 2** of the ES).

18B.5.26 However, further analysis of information and data available from the location of Hinkley Point B (Section 19.6, **Volume 2** of the ES) indicates that there appears to be no correspondence in *Macoma* communities with the thermal contours of the Hinkley Point B plume. It is concluded therefore that there is no discernible adverse effect on the *Macoma* population within the footprint of the thermal plume from Hinkley Point B. Thus it therefore follows that there is unlikely to be any significant impact on the *Macoma* as a result of Hinkley Point C discharging as the thermal plumes do not appear to significantly overlap. Hence impacts on marine invertebrates are unlikely to be significant and a change in biological status is not predicted.

18B.5.27 In terms of fish, the thermal plume covers a very small proportion of the area of interest for the fish assemblage (for the purposes of this assessment, deemed to be the Bristol Channel / Severn Estuary and beyond rather than at the water body level Ref. 18B.3). The plume however, covers a larger area available to intertidal fish.

18B.5.28 Adult fish are mobile and therefore are likely to respond to a thermal stimulus by moving away or towards it. Hence they are deemed to have a high level of resilience to any potential effect of the predicted localised increase in water temperature.

18B.5.29 For migratory fish, the temperature differential at the edge of the plume could act as a physical barrier to migratory passage thus disrupting life cycles and potentially the ability to reproduce. Calculations for the assessment of potential barriers to fish migration undertaken to assess potential impacts on water quality show that the potential for thermal occlusion of the estuary which could impede migratory fish is unlikely (Ref. 18B.3).

18B.5.30 Juvenile life stages are considered to be less able to resist exposure to the thermal plume but several species recorded in the Bridgwater Bay area appear to have biogeographic ranges that include warmer locations so can be presumed to be relatively tolerant of warmer waters (Ref. 18B.3).

18B.5.31 Given the above and the very small area relative to the wider estuary likely to be impacted by the thermal plume, the cross-sectional calculations that predict that barriers are unlikely to be an issue to fish migration and their relatively high resilience (Ref. 18B.3), impacts on fish assemblages and migratory fish due to the thermal plume are unlikely and therefore a change in biological status is deemed unlikely.

iv Impacts Associated with the Discharge of Cooling Water (Physical Parameters – Dissolved Oxygen)

18B.5.32 Other issues associated with the cooling water discharge include the impacts of increased temperature on dissolved oxygen (DO) and un-ionised ammonia concentrations.

18B.5.33 DO is relevant because an increase in temperature directly affects the amount of oxygen dissolved in water as the solubility of gases reduces. Currently the Bridgwater Bay water body is considered to be at high status for this parameter but a status is not recorded for the Parrett Estuary water body.

18B.5.34 The approach used to investigate the extent of oxygen consumption (or demand) from saturation was to use data for August when DO levels are likely to be close to their lowest levels and salinities would be high. Details of the methodology used can be found in TR186 (Ref. 18B.4). The assessment is therefore extremely precautionary as these conditions only exist for a very limited time of the year.

18B.5.35 WFD includes threshold values for TraC waters and the standard for 'Good' status is 4.0 $mg.l^{-1}$ to 5.7 $mg.l^{-1}$ for marine waters. In summary, the results for the DO concentration in the area influenced by the plume is reduced to around 6.5 $mg.l^{-1}$ and when the biological oxygen demand is taken into account, a wider area of lower DO concentrations is noted. For Hinkley Point C alone, this equates to a mixing zone (in relation to high status) of 2% and 3% of the sea bed and surface of the Bridgwater Bay water body respectively. For both Hinkley Point B and Hinkley Point C discharging at 100% the mixing zones increase to 6% and 8% of the sea bed and surface respectively. Since this mixing zone is relatively small and more importantly will only occur for very short periods of the year, impacts on high status for the DO parameter are not predicted for the Bridgwater Bay water body.

18B.5.36 For the Parrett Estuary water body, the oxygen concentration remains consistently above 4.4 $mg.l^{-1}$ for all combinations of Hinkley Point C and Hinkley Point B which is within the boundary conditions for good status. The objective for good ecological potential will therefore not be compromised.

18B.5.37 In terms of ammonia, the un-ionised form of ammonia is more toxic to aquatic biota than the ionised form and the proportion of un-ionised ammonia increases with increasing temperature and pH, but decreases with increasing salinity. There is therefore the potential for the increased temperature of the cooling water discharge to alter the natural equilibrium of ammonia:un-ionised ammonia, whereby concentrations of the more toxic un-ionised form would increase. Again modelling was undertaken (for full details please refer to TR186 Ref. 18B. 4).

18B.5.38 In summary, the maximum resulting un-ionised ammonia concentration contour was 11.2 $\mu g.l^{-1}$ for Hinkley Point C operating at 100% alone (Run C). For Hinkley Point B operating at 100% in addition to Hinkley Point C at 100%, the maximum resulting un-ionised ammonia concentration contour was 16 $\mu g.l^{-1}$. For all model runs, the maximum value is less than the EQS of 21 $\mu g.l^{-1}$ annual average for un-ionised ammonia. A deterioration in overall water body status for either the Parrett Estuary water body or the Bridgwater Bay water body is, therefore, not anticipated.

v Water Quality Impacts Associated with the Discharge of Cooling Water (Chemical Parameters)

18B.5.39 During the operational phase the cooling water is predicted to contain the following main contaminants:

- metals (aluminium, copper, chromium, iron, manganese, nickel, lead and zinc);
- boric acid;
- boron;
- lithium hydroxide;
- hydrazine;
- morpholine and associated breakdown products: ethanolamine, acetates, formiates, glycolates, oxalates;
- total nitrogen as N, un-ionised ammonia;

- phosphates;
- detergents;
- chemicals used for maintenance of demineralised plant reverse osmosis membranes, e.g. ATMP, HEDP, Phosphoric acid and Sodium Polyacrylate; and
- suspended solids.

18B.5.40 Modelling of all process chemicals to be discharged to the marine environment via the cooling water discharge has been undertaken according to an Environment Agency H1-type assessment methodology (Ref. 18B.15). The first tier of assessment screens out discharges considered to be of no environmental significance. Chemical parameters found to be at significant concentrations (i.e. above EQS) are then subject to more detailed analysis for a range of scenarios. It was concluded that the resultant depth average environmental concentrations at 100 m and 500 m from the discharge point are below concentrations of environmental significance for all chemicals considered, with the exception of hydrazine and total residual oxidants (TRO).

18B.5.41 It should be noted that the discharge of inorganic nitrogen was considered as part of the H1 assessment. In summary it was concluded that the concentrations of nitrogen within the proposed discharge would not change the current nutrient quality status of the receiving water. The assessment also indicated that the current status of the Bridgwater Bay water body, based on background survey information collected for the EIA, could be at good status for this parameter and will remain at good status with the presence of the discharge.

18B.5.42 In order to further assess the potential impact of hydrazine on marine water quality, an extension of the modelling described for the thermal plume was undertaken. Further detail is provided in BEEMS TR 186 (Ref. 18B.4) and Section 18.6, **Volume 2** of the ES.

18B.5.43 Hydrazine breaks down rapidly into nitrogen and water, and so by storing it prior to discharge concentrations can be significantly reduced. Breakdown may also be enhanced by thermal degradation, which produces ammonia as a breakdown product. Treatment is already part of the existing EPR design for Hinkley Point C and therefore is accounted for in the following assessment results.

18B.5.44 Since an EQS is not available for hydrazine, calculations of potential impacts use the chronic Predicated No Effect Concentration (PNEC) concentration of 0.0004 µg/l. Further information in relation to this standard is provided in TR186 (Ref. 18B.4). **Figure 18B.7** and **Table 18B.9** show the results for Hinkley Point C only as Hinkley Point B is not consented to discharge hydrazine.

Table 18B.9: Prediction of Plume Area Exceeding the Hydrazine PNEC

Surface/seabed	Area of plume >0.004ug/l	
	Parrett Estuary	Bridgwater Bay
Surface	7 (0.1%)	184 (2%)
Seabed	3 (0.04%)	74 (0.8%)

18B.5.45 Only the subtidal soft sediments located adjacent to the outfall would be exposed to hydrazine concentrations that exceed the chronic PNEC. Limited toxicological data are available against which to assess potential sensitivity of infaunal invertebrates to hydrazine and this is detailed in TR 184 (Ref. 18B.3).

18B.5.46 It is therefore possible that some toxic effects could arise through the use of hydrazine, but only in the localised vicinity of the discharge outfall where the PNEC could be exceeded. Given the very small area affected and the suggested tolerance of organisms to the predicted concentrations, it is considered that any toxic effects associated with this substance would not be significant and, therefore, a deterioration in chemical status unlikely.

18B.5.47 In relation to chlorination, within the General Design Assessment (GDA), under normal conditions for EPR units, worst case chlorination would involve dosing to $0.5mg.l^{-1}$ of active chlorine applied sequentially once every 30 minutes per cooling channel.

18B.5.48 However, the review of operational information and the risk assessments undertaken for biofouling at Hinkley Point B identify that, unlike other sites operated in the UK by EDF Energy, chlorination of the intake heads, shafts, tunnels and forebays is not required to control biological fouling. This local understanding is exceptional, and the standard operating procedure that applies to EDF Energy's coastal power stations requires that a means of dosing nonetheless is maintained in case of need.

18B.5.49 Detailed analysis regarding the modelling approach used to determine the potential impacts associated with discharges of chlorine to the subtidal area is provided in BEEMS TR186 (Ref. 18B.4). The model outputs for the chlorination assessment were used to calculate areas of the plume at the surface and bed that exceed the chlorine EQS of 0.01 $mg.l^{-1}$ expressed as total residual oxidants. These are presented in **Table 18B.10** and **Figures 18B.8** and **18B.9**.

Table 18B.10: Prediction of Plume Area Exceeding the TRO Standards

Run	Surface/seabed	Area of plume >$0.01mg.l^{-1}$ (hectares)	
		Parrett Estuary	Bridgwater Bay
C (HPC $0.2mg.l^{-1}$)	Surface	0	159 (2%)
	Seabed	0	63 (1%)
E (HPC 0.2 $mg.l^{-1}$ & HPB 0.3 $mg.l^{-1}$)	Surface	46 (1%)	205 (2%)
	Seabed	67 (1%)	65 (1%)

18B.5.50 The Bridgwater Bay water body is most affected by the TRO plume at the surface with areas that exceed the EQS for TRO calculated at 205 hectares. This equates to 2% of the Bridgwater Bay water body. For the Parrett water body, the TRO EQS is not exceeded at the surface or at the seabed and, therefore, impacts on the water body and its chemical status are not predicted.

18B.5.51 **Figures 18B.8** and **18B.9** show that the area of EQS exceedance within the Bridgwater Bay water body is relatively small and is generally restricted to the local area of the discharge. As a consequence the majority of habitats are unlikely to be impacted by the plume.

18B.5.52 The only habitat potentially at risk from the TRO plume is therefore the subtidal soft sediments in the immediate vicinity of the outfall. Toxicity testing with two abundant species in the intertidal mudflat (found in the subtidal soft sediments) has been summarised in BEEMS Technical Report TR163 (Ref. 18B.5) and further described in the HRA Report (Ref. 18B.2). It is concluded that there may therefore be some mortality within the area exceeding the EQS however this area is likely to be minimal. Impacts on subtidal mudflat habitats associated with chlorination are therefore predicted to be minimal.

18B.5.53 In terms of chemical contaminants in the plume impacting on the fish assemblages and migratory species, again only a very small area relative to the area of interest would be impacted by exceedances of standards (see summary of water quality effects above).

18B.5.54 These concentrations are not predicted to occur outside of the area immediately adjacent to the discharge. Again as for the thermal plume, adult fish are mobile animals and are expected to respond to a chemical plume by avoiding it. Similarly for migratory fish, a chemical plume could act as a physical barrier to the migratory passage, disrupting the species' life cycles and, potentially, ability to reproduce (Ref. 18B.2). Such an effect appears unlikely in Bridgwater Bay given the relatively small area of chemical impact relative to the available habitat.

18B.5.55 Planktonic life stages are less able to resist negative effects of TROs (Ref. 18B.16), so species reproducing in the area exposed to the plume may suffer some degree of impact. However, the survey data does not suggest that there is any spawning activity or aggregation of planktonic stages in the area of the discharge point (Ref. 18B.3).

18B.5.56 Given the very small area of impact compared and the potential for fish to avoid the plume, it is deemed that effects on fish are unlikely.

18B.5.57 Overall, therefore, impacts on biological and chemical parameters are not deemed to be significant and deterioration in both biological and chemical status is not anticipated.

vi Impacts Associated with the Intake of Cooling Water

18B.5.58 The abstraction of cooling water from the Bristol Channel for the Hinkley Point C nuclear power station will carry with it the risk of fish impingement and entrainment potentially resulting in the loss of fish from estuarine populations.

18B.5.59 Data on impingement are available from the Hinkley Point B monitoring dataset and the Comprehensive Impingement Monitoring Programme (CIMP) carried out over a 12 month period. Full details of this work are provided in Section 19.5, **Volume** 2 of the ES.

18B.5.60 Using these data, a prediction of the potential impingement of fish has been undertaken by the Centre for Ecology of Fisheries and Aquaculture Science (Cefas) (Ref. 18B.17). Cefas concluded that, without mitigation, impingement at Hinkley Point C would increase about fourfold over that of Hinkley Point B simply as a result of the increased abstraction of cooling water.

18B.5.61 Given the potentially large increase in impingement for Hinkley Point C, assessment work has taken into account the potential reductions in impingement that could possibly be achieved by implementing appropriate mitigation measures. These measures are also viewed as Best Available Technology (BAT) and implementation of such measures has been viewed as an important aspect of the overall design of the water cooling system.

18B.5.62 To summarise the findings of the ES, the cooling water system for the power station has been designed with low velocity intake structures in order to reduce potential impingement losses. In addition, the installation of an acoustic deterrent system would further reduce impingement and a FRR system will also be installed. Further details of these measures are provided in TR148 (Ref. 18B.7) and BEEMS TR197 (Ref. 18B.6). If these proposed mitigation measures function as designed, the impingement losses at Hinkley Point C are calculated to be less than or similar to those of the existing Hinkley Point B station. Impacts on biological status in relation to fish are not therefore predicted.

18B.5.63 A significant number of organisms (juvenile fish and crustaceans, and plankton) would, however, inevitably enter with the cooling water. Plankton plays an important role in the ecological function of the estuary and is a specific biological element detailed under WFD. Holoplankton (dominated by copepods) provide an important food resource for a large range of organisms that reside within or pass through the estuary, notably juvenile fish and crustaceans. The larval stages of many of the invertebrate species that comprise the intertidal and subtidal communities of benthic substrates in the estuary make up the meroplankton.

18B.5.64 Consequently, significant losses of plankton through entrainment could have implications for the overall population dynamics of a range of organisms either directly through the loss of larval stages or indirectly as a reduction in prey availability. Similarly, a significant reduction in phytoplankton could lead to a reduction in productivity and affect nutrient flow through the estuarine foodwebs.

18B.5.65 The smaller organisms (plankton, eggs and larvae of fish and crustaceans) that pass through the drum screens would be entrained in the cooling flow and continue on through the power station cooling system to be returned via the thermal discharge back to the Bristol Channel. Significant proportions of these entrained organisms are expected to survive the entrainment process to re-enter the estuarine ecosystem, however, they are at risk of a number of mechanical, hydraulic, pressure, temperature and chemical related stressors during this passage. The survival of entrained individuals is dependent upon the species, their developmental stage and size, physiological condition and the design of the cooling water system.

18B.5.66 Each group has been considered in detail in both the ES (**Chapter 19**, **Volume 2**) and the HRA Report (Ref. 18B.2) and in summary both assessments do not predict significant impacts on any plankton component. Although the assessment is undertaken at the estuarine scale (i.e. the Bristol Channel), it is considered that it is appropriate for the impacts to be scaled down to a water body level and similar conclusions reached. This is because it is assumed that the plankton distribution is relatively even across the study area.

e) Cumulative Impact Assessment (Water Quality)

i Elements Assessed

18B.5.67 Two elements of the proposed development that could give rise to cumulative effects on marine water quality were considered in the ES (Section 5.9, **Volume 11** of the ES). These are summarised below.

ii Increases in Suspended Solids

18B.5.68 Each of the elements of the project that could give rise to increases in suspended solids are located some distance away from one another but within the Bridgwater Bay water body. For example, the jetty is located approximately 800 m away from the foreshore discharge. Many of the sediment generating activities would also be separated temporally, e.g. the sea wall and construction outfall would be carried out at different times to other sediment generating activities. Control measures would be in place to reduce the suspended solid concentrations within discharges from the land. Predicted impacts associated with the jetty dredging and cooling system drilling and dredging operations, although difficult to control, are expected to be insignificant, predominantly due to the already naturally high concentrations of suspended solids and strong tidal currents. Any temporary increases in suspended solid concentrations within the vicinity of Hinkley Point are, therefore, likely to be dispersed to background concentrations rapidly.

18B.5.69 Given the temporary nature of each of the predicted impacts, cumulative impacts within each water body are not predicted and, therefore, neither are changes to WFD status.

18B.5.70 For the Parrett Estuary water body, impacts in relation to Combwich Wharf are deemed to be the same as those assessed for Combwich Wharf alone as this activity is remotely located and is predicted to be of low significance in terms of impact. No cumulative impacts on the Parrett Estuary water body are therefore predicted.

iii Increases in Contaminants

18B.5.71 All of the assessments that have considered the potential for contamination within the existing Hinkley Point C site soils have concluded that contamination is either comparable to baseline conditions or the risk of finding significant contamination is low. The risk of releasing contaminated sediment into surface water during the site works is therefore low. Additionally, control within the drainage systems would be put in place in order to reduce the potential risk of discharging contamination to the surface water drainage system.

18B.5.72 Any water quality contamination associated with sediment mobilisation resulting from dredging, offshore drilling and scour associated with offshore infrastructure is predicted to be minor and would occur geographically remotely from one another. Cumulative impacts in relation to impacts on either of the water bodies are not therefore, predicted.

18B.5.73 As above, for the Parrett Estuary water body, impacts in relation to Combwich Wharf are deemed to be the same as those assessed for Combwich Wharf alone as this activity is remotely located and is predicted to be of low or minor significance. No cumulative impacts on the Parrett Estuary water body are therefore predicted.

f) Cumulative Impact Assessment (Marine Ecology)

i Habitat Damage Due to Cross-Shore Works

18B.5.74 Works across the shore include: jetty construction, operation and removal; drilling of the horizontal tunnels for the cooling water structures; and sea wall construction. The impacts of these activities would be additive in terms of the areas impacted, except where access corridors coincide.

18B.5.75 Overall it is concluded in Section 19.6, **Volume 2** of the ES that while the foreshore at Hinkley Point may be subject to a number of construction related disturbance events, the totality of these events would be one of prolonging the overall period of effect across distinct parts of the foreshore, rather than intensifying impacts, such that a longer term loss or change in habitat function would occur. Impacts on individual habitats are therefore unlikely to lead to a significant cumulative effect. Impacts on the biological parameters of the water bodies are not, therefore, deemed to be significant and a change in status is not predicted.

ii Habitat Damage Due to Subtidal Works

18B.5.76 The offshore works which could result in cumulative impacts include the installation of jetty piles, dredging associated with the berthing pocket of the jetty, and the installation of the vertical shafts for the cooling water system.

18B.5.77 The jetty will be in its operational phase during the installation of the vertical shafts and, hence, no cumulative impacts on marine life through increased suspended sediments or disturbance would arise. The capital dredging for the berthing pocket will also have been complete, but there is the potential for maintenance dredging of the berthing pocket to overlap with the installation of the vertical shafts.

18B.5.78 However, the areas over which these activities will occur are relatively small and impact on subtidal communities typical of the study area. Cumulative impacts are therefore not predicted on the water bodies and, consequently, a change in status is similarly not predicted.

18B.6 Stage 4: Identification and Evaluation of Measures

a) Introduction

18B.6.1 Although impacts at a water body level have not been identified, this section summarises details of the proposed monitoring for the assessed activities in order to provide further information on the assessments made and to ensure that the mitigation measures included within the design are effective. For further information, please refer to Sections 18.10 and 19.10, **Volume 2** in the ES.

b) Coastal Geomorphology and Hydrodynamics

18B.6.2 For operational reasons, there will be a need to establish and maintain monitoring of vertical profiles of mud density within the temporary aggregate jetty berthing pocket. Maintenance dredging is anticipated when densities increase to a magnitude that will permit this activity to be both needful and effective.

18B.6.3 A 'Waverider' directional wave and temperature recording buoy has been established in 10m of water off Hinkley Point since December 2008. This buoy is maintained as a part of the BEEMS project although it has also been adopted as a component of the national WaveNet wave monitoring network, managed by Cefas. This deployment will be maintained throughout the construction period of Hinkley Point C both to continue to secure a baseline of local wave conditions and provide management information for operations associated with the temporary aggregate jetty. The need for longer term maintenance of this deployment will be dependent on operational safety case considerations at Hinkley Point C.

c) Water Quality during Operation

i Thermal Plume

18B.6.4 Field investigations will be undertaken in order to assess the behaviour of the thermal plumes under known tidal and meteorological conditions, allowing comparison of the results with previous modelled estimates. Additional model runs may prove necessary in order to replicate the field conditions found at the time.

18B.6.5 There will be a need to gather a sufficient body of empirical data on these operations before it becomes possible to validate these models. Upon commissioning therefore, a transect section will be established and sampled initially at frequent intervals (100 m) close to the discharge and 0.5-1 km at more remote sites, monthly, over a period of 12 months. The spatial distribution of samples will be reviewed on the basis of initial results. Parameters to be measured include:

- temperature at surface, -2 m and near bed;
- dissolved oxygen;
- (unionised) ammonia;
- hydrazine (if included in discharge consent);
- dissolved nutrients;
- dissolved metals; and
- selected organics used by HPC e.g. ethanolamine.

18B.6.6 Over the operational life of the plant, continuous monitoring of the cooling water discharge temperature will be maintained.

ii Monitoring of Bio-fouling

18B.6.7 Monitoring will be maintained of heat exchanger efficiency, the incidence of fouling within the plant, and for the presence of typical fouling species on local shores. The use of chlorination will be justified solely on the basis of empirical evidence from these sources.

18B.6.8 Such surveillance is currently maintained by Hinkley Point B and elements of this, adapted as appropriate given the difference in plant design (primarily the offshore position and low flow nature of the HPC intake design), will be adopted by the HPC operator.

18B.6.9 Should chlorination be applied on any occasion, daily sampling of the final effluent stream and TRO analysis by colorimetric means will be maintained throughout. The following chlorination by-products (CBPs) will also be monitored via initial characterisation and subsequent weekly sampling:

- Bromoform;
- Bromodichloromethane;
- Chlorodibromomethane;
- Monobromoacetic acid;
- Dibromoacetic acid; and
- 2, 4, 6, tribromophenol.

18B.6.10 Following initial characterisation, subsequent routine monitoring for bromoform alone is likely to be sufficient.

d) Ecological Monitoring during Operation

i Invertebrate Populations on Stert Flats

18B.6.11 The existing baseline of seasonal studies of *Macoma* and other key invertebrate species on Stert Flats will be extended in order to elaborate on the existing understanding of within-year and between-years variance. After an initial 3 year period a reduced sampling strategy will be implemented in order to track longer term trends in these populations.

ii Efficacy of Fish Protection Measures

18B.6.12 Precautionary estimates have been used is assessing the mitigation benefit of the AFD (acoustic fish deterrent) and FRR systems that will be installed. There will therefore be a need to prove that the minimum performance standard, based upon these estimates, has been met early in the operational life of the station. Thus, trials will be carried out at that time and any adjustments made to these systems should this prove necessary. A fish impingement/entrainment programme will also be developed and implemented.

18B.7 Conclusions

18B.7.1 The two WFD water bodies within the study area for the proposed developed are the Parrett Estuary and Bridgwater Bay. A screening and scoping assessment has considered all activities that potentially could impact on these marine water bodies and has subsequently concluded that, based on trigger levels within *Clearing the Waters* guidance (Ref. 18B.9) and impact assessments from the ES, there are three potential activities that could either cause a deterioration in water body status or potentially threaten the ability of the water bodies to meet their objectives.

18B.7.2 A stage 3 assessment was, therefore, carried out on the three activities and, using information already available, determined that the proposal will not cause deterioration in water body status or cause potential problems with respect to the ability of the water body to meet its objectives in the future. In order to ensure that these conclusions are correct, a programme of monitoring is proposed.

APPENDIX 19A: CROSS-SHORE HYDRAULIC MODELLING AND SELECTION OF POINT OF DISCHARGE

CONTENTS

FIGURES

[This page is intentionally left blank]

APPENDIX 19A: CROSS-SHORE HYDRAULIC MODELLING

19A.1 Context

19A.1.1 On the northern half of the Hinkley Point C (HPC) site, within Built Development Areas East and West, surface drainage run-off will initially be discharged into the HPC drainage ditch and thence discharged to the foreshore. At an early stage of construction, Water Management Zones (WMZs) will be created along the ditch to attenuate flow (which will be restricted to greenfield run-off rates) and suspended solids concentration (which will be restricted to 250mg.l^{-1}). Once the spine drains (the central drainage channels) have been installed, this ditch will be removed, and a new discharge point to the foreshore in its stead.

19A.1.2 The purpose of this **Appendix 19A** to **Chapter 19** of the ES is to review the assessment that has led to the selection of that new discharge point.

19A.1.3 The spine drains will receive: all surface drainage from the northern area of the site (Built Development Areas East and West); groundwater pumped from the deep well system serving deep excavations; treated sanitary effluent from package treatment plants; and any waste water from tunnel excavation works for the cooling water and fish return systems. Each of the three spine drains will be served by its own WMZ to attenuate flows and ensure that the conditions of the Environmental Permit are met, in terms of discharge flow and water quality.

19A.1.4 As the development progresses and until the main cooling water discharge route becomes available, it will also be necessary to discharge early ('cold-flush') commissioning discharges.

19A.1.5 All such effluent streams will receive the appropriate level of treatment, so as to satisfy all applicable Environmental Quality Standards at the point of discharge.

19A.2 Options considered

19A.2.1 Three options have been considered for discharge across the intertidal area, as follows (see **Figure 19A.1**; Ref. 19A.1).

19A.2.2 **Option 1: Three discharge outfalls**. This option would involve the three main spine drains discharging directly to the upper intertidal area through their own outfall structures at the cliff face at 9m AOD.

19A.2.3 **Option 2: One single outfall at Location A**. This option would involve spine drains in the same positions as Option 1, but cut short of discharging to the intertidal area by a collector drain running parallel to the shore (on the landward side of the cliff, within the application site). This collector drain would then discharge to the upper intertidal area at 7.5m AOD, landward of the location of the historical construction dry dock (buried beach feature), used in the construction of Hinkley Points A and B.

19A.2.4 **Option 3: One single outfall at Location B**. This option would be similar to the single outfall at Location A, being serviced by a collector drain and discharging to the upper intertidal area at 7.5m AOD, except that the outfall discharge pipe would be at a similar location to the existing HPC Ditch, which runs through Built Development Areas West and East, as described above.

19A.3 Receptors

19A.3.5 There are a number of potentially sensitive receptors within the local intertidal area. **Figures 19.08-19.10**, within **Volume 2, Chapter 19**, show the distribution of the various biotopes involved.

19A.3.6 The two most significant biotopes involved in considering potential outfall locations are those associated with the reef-building polychaete worm, *Sabellaria* spp., and the turf-forming red alga, *Corallina* spp. The *Sabellaria* interest is described in 19A.5b)i and 19A.5c)ii, below, and the *Corallina* interest in 19A.5b)ii and 19A.5c)iii.

19A.4 Assessment Methodology

19A.4.1 The behaviour of the cross-shore effluents associated with each of these outfall scenarios has been compared and the effect on intertidal habitats assessed, using numerical modelling of the lateral spread of the discharges across the intertidal area and relating the findings to habitat and biotope mapping.

19A.4.2 A digital terrain model (DTM) of the intertidal area, utilising light detection and ranging (LiDAR) data (Environment Agency), was established. These data had a grid resolution of 1m and a vertical accuracy of ±0.15m.

19A.4.3 To determine likely quantities and lateral extent of freshwater discharges to the shore during the site preparation and construction works, a number of hydrological modelling scenarios were considered, as agreed with Natural England and the Environment Agency (technical consultation, held 24th May, 2010). These provide an estimation of the potential, lateral spread of freshwater discharges to the intertidal area for each of the three options. Baseline, i.e. pre-development, drainage discharge was modelled for 43% (**Figure 19A.2**) and 3.33% (**Figure 19A.3**) annual exceedance probability (AEP) events. AEP is the probability, given as a percentage, associated with the return period of an event. Thus an event-of-return period of 100 years has an AEP of 1% (also known as, e.g. the 100-year flood, or 1:100 year flood); 50 years, 5%; 30 years, 3.33%.

19A.4.4 Two-dimensional (2D) modelling was then undertaken to simulate the flood extents, using the TUFLOW numerical hydraulic modelling code (Ref. 19A.1).

19A.4.5 For the purposes of enveloping worst case estimates associated with the expected site construction discharges, further modelling was undertaken in order to simulate the additional volumes involved.

19A.5 Assessment

a) Introduction

19A.5.1 The location of the outfall options in relation to the intertidal area and distribution of *Sabellaria* and *Corallina* related biotopes is given in **Figure 19A.2**. A service road would be constructed to give vehicular and construction worker access to the foreshore and outfall structure during the preparation and construction phases. This service road would be located at the point where the existing HPC drainage ditch exits onto the intertidal area and it would be less than 100m in length. Any disturbance would be restricted to this short stretch of the upper intertidal area, above Highest Astronomical Tide (HAT). The biotope of this area is described under the EUNIS classification as 'barren, littoral shingle' (see **Volume 2, Chapter 19, Figures 19.08, 19.09** and **19.10**).

19A.5.2 Although the upper intertidal areas lie within the Severn Estuary SAC, SPA and Ramsar site, none of the features within the upper shore area is a qualifying feature and these biotopes are widespread along the intertidal zone, throughout the study area, which extended as far as Watchet approximately 15 km to the west of Hinkley Point.

19A.5.3 The upper intertidal habitat is not regularly used by large numbers of roosting or foraging birds. Accordingly, the receptor value is assessed as low. The area of the works would be subject to disturbance, in addition to natural events, but such impacts are not expected to be of any greater magnitude than high-tide storm events. Furthermore, following a natural storm event, it is unlikely that any evidence of foreshore access would remain. The impact magnitude is therefore assessed as very low and the significance of the potential impact as negligible.

19A.5.4 The volumes and lateral extent of freshwater discharged to the foreshore would impact upon the intertidal ecology during low-tide periods by causing an influx of water of a different quality and salinity into retained saline pools. The intertidal ecology is specifically adapted to tidal cycles of emersion and immersion as well as seasonally variable extremes of rainfall and drying and is thus tolerant of wide salinity range. This is demonstrated by the character of many of the biotopes involved (**Volume 2, Chapter 19, Figures 19.8** to **19.10**), described under EUNIS as being of 'variable salinity'. Inundation by increased levels of freshwater, nevertheless, has some potential to cause an adverse impact upon local communities, either through scour and displacement or through osmotic stress.

b) Effects of Freshwater Discharge

i. *Sabellaria*

19A.5.5 Section 5 of the advice given under Regulation 33(2)(a) of the Conservation (Natural Habitats, &c.) Regulations (Ref. 19.114 in Chap. 19) states that *Sabellaria* reef is of moderate vulnerability to changes in salinity and suspended solids. For the purposes of this assessment, due to its moderate vulnerability, *Sabellaria* reef thus considered to be of **medium** value.

19A.5.6 The main areas of *Sabellaria* reef local to Hinkley Point C lie in the lower intertidal area, approximately 300m offshore at the eastern end of the application site. There is also a small area approximately 200m directly downshore from both Option 2, Location A and Option 3, Location B, as well as the existing HPC drainage ditch discharge location (**Figure 19A.2**). While the main areas would be unaffected by any of the proposed outfall options, this smaller area could be affected; this feature has been described as being of low to moderate 'reefiness' (see **Volume 2, Chapter 19**).

19A.5.7 The modelled routes of the discharge of freshwater during a 3.33% AEP event show that the flow falls short of areas of *Sabellaria* reef for both Outfall Option 1 (**Figure 19A.4**) and Outfall Option 2 (**Figure 19A.5**) whereas there is potential for intertidal *Sabellaria* reef to be inundated with freshwater from Outfall Option 3 at Location B (**Figure 19A.6**). As the *Sabellaria* reef is on the lower intertidal area, exposure at low tide would be infrequent and brief. Impacts are thus predicted to be direct and temporary.

Options 1 and 2 (*Sabellaria*)

19A.5.8 *Sabellaria* reef is considered to be of **medium** value, as it is an Annex I habitat of international importance, designated under the Habitats Directive, although not one considered to be sensitive to either moderate variations in salinity, flow, or high turbidity. The magnitude of the effect of Options 1 and 2 is considered to be **very low**, given that *Sabellaria* currently exist in the line of the present discharge (**Figures 19A.2 and 19A.3**) and appear to be unaffected by it and also given that the modelled discharges fall short of reaching the *Sabellaria* (**Figures 19A.4** and **19A.5**). The proposed outfall developments in Options 1 and 2 are therefore assessed as having a **minor** impact on *Sabellaria* reef.

Option 3 (*Sabellaria*)

19A.5.9 As previously mentioned, *Sabellaria* is seemingly unaffected by the current discharge. However, the greater volumes modelled in Option 3, discharged from Location B may have some impact. The magnitude of this impact on the **high**-value/sensitivity *Sabellaria* is predicted to be **low**. Consequently, an overall impact of **minor,** adverse significance is predicted.

ii. *Corallina*

19A.5.10 The geological configuration of the foreshore at Hinkley Point, with a wide platform of rock pavement gently dipping seawards in the lower intertidal zone, provides a niche for the development of *Corallina* turf habitat. This is especially so where long-shore drainage overtops scarps in the pavement during low-tide periods to form wide spillways. These wide areas of turf occupying the wetted areas of these spillways are termed '*Corallina* run-offs' and are the most distinctive feature of the HPC intertidal shore. This turf habitat is considered to be a notable sub-feature of the SAC. For the purposes of this assessment, given the relatively low vulnerability of this species to variable salinity and high turbidity, the sensitivity/value it taken to be **medium**.

19A.5.11 While it is generally considered that *Corallina* is relatively tolerant of infrequent and short-term changes in salinity, it is important to draw a difference between acute and chronic freshwater inundation.

19A.5.12 Periodic storm-event discharges of freshwater from land and direct precipitation to the intertidal shore (both of which involve large but infrequent volumes of water – the acute condition) are unlikely to cause adverse effects on *Corallina*, since diurnal tidal immersion will regularly refill the long-shore intertidal drainage features with seawater. Ponded seawater in these features will protect *Corallina* turf from desiccation at low water and maintain some salinity when freshwater is discharged. However, should freshwater regularly flush these pools, due to constant discharges from site preparation and construction activities (the chronic condition), there is potential for the *Corallina* to be adversely affected by chronically low salinity, although this will again be limited by tidal immersion. In addition, there is potential for the *Corallina* turf to be smothered by sediment deposition (addressed in 19A.5c)iii, below).

19A.5.13 The locations of the three outfall options in relation to recorded areas of *Corallina* are shown in **Figure 19A.2**. *Corallina* habitat is present approximately 100m downshore of each of the three discharge points of Option 1. *Corallina* habitat is also present in the intertidal zone approximately 150m downshore from the proposed discharge location of Option 2, Location A, on the eastern edges of the historical berthing dock. For Option 3, Location B (beside the current location of the HPC drainage ditch), *Corallina* is present in the intertidal zone 100m downshore and slightly to the west of the proposed discharge point.

19A.5.14 Hydraulic modelling of discharged flows during the low tide period has been undertaken to assess the likely extent of freshwater inundation of the foreshore, based on a 3.33% AEP event (see Figures **19A.4, 19A.5** and **19A.6**). It should be noted that 99.5% of high tides (based on records from Hinkley Point tide gauge) inundate the areas of *Corallina*. Thus, for the most part, even the *Corallina* furthest inshore is not exposed for longer than around 12.5h (given two tidal cycles per diem). Between tidal cycles, the *Corallina* would, however, be immersed in freshwater flowing from the outfall discharge and collecting in the gullies.

19A.5.15 Taking the above into account, the potential impact of each of the three discharge options on *Corallina* is identified below.

Option 1 (*Corallina*)

19A.5.16 Option 1, involving three outfalls, would potentially result in adverse impacts on *Corallina* and the habitat that it maintains, due to the proximity of the outfalls to extensive, recorded areas of this habitat. The modelled lateral extent of the discharge of freshwater during a 3.33% AEP event shows that approximately 40% of the total area of *Corallina* would be inundated (**Figure 19A.4**). The impact would be likely, adverse, indirect and widespread across the foreshore. The value of the *Corallina* has been assessed as **medium.** The overall magnitude of the impact is predicted to be **medium**, as the receptor may experience some degradation and possible reductions in biomass beyond the range of natural variability, but limited to areas within and adjacent to the development. Consequently, it is assessed that the impact would be of **moderate**, adverse significance due to the location of the outfalls in proximity of the *Corallina*.

Option 2 (*Corallina*)

19A.5.17 Option 2, a single outfall at Location A, runs just to the west of the most easterly patch of Coralline turf (**Figure 19A.5**). It is therefore predicted to be an impact of only **very low** magnitude to the **medium**-value *Corallina*. Overall, a **minor** impact is anticipated.

Option 3 (*Corallina*)

19A.5.18 Option 3, a single outfall at Location B (HPC drainage ditch), would result in adverse impacts on a small area of *Corallina* and the habitat that it maintains, due to the modelled, lateral extent of the discharge (**Figure 19A.6**). The impact is likely and would be adverse, direct and localised. However its overall magnitude is predicted to be **low**, with some limited degradation of the habitat. Hence it is anticipated that the impact of freshwater discharge from Option 3 would be of **minor,** adverse significance due to the proximity of the outfall to (**medium**-value) *Corallina*.

iii. Assessment Outcome

19A.5.19 For *Sabellaria*, each of the options would bring only minor effects from freshwater discharge. For *Corallina*, Options 2 and 3 would bring minor effects, whereas impacts from Option 1 would be moderate. Therefore, either the single outfall at Location A or the single outfall at Location B would be the best choice of discharge location, to mitigate impacts of freshwater discharge.

c) Effects of Sediment Deposition

i. Introduction

19A.5.20 Sediment-laden water would be generated from a range of site preparation activities in the northern areas of the site (Built Development Areas East and West). The main source of these sediments would be surface drainage, arising from areas of bare earth and any requirement to dewater excavations. Consideration has been given to the extremely high concentrations of suspended sediments that are naturally present within the Inner Bristol Channel when assessing potential impacts. However, there is potential for discharges with concentrations of suspended solids (given a mean baseline equivalent concentration of 250mg/l) to cause temporary smothering of intertidal fauna and flora, particularly *Corallina* turf habitats, during low-tide periods.

ii. *Sabellaria*

19A.5.21 As described in 19A.5.5, *Sabellaria* is moderately vulnerable to changes in suspended solids. The *Sabellaria* reefs are a qualifying feature of the Severn Estuary SAC.

19A.5.22 The more open structure of the tubes constructed by the *Sabellaria* worms provides opportunities for a range of invertebrate species associated with hard-bottom habitats to co-exist there (Ref. 19A.2).

19A.5.23 Given the shifting nature of sediments in the Severn Estuary, *Sabellaria* is subjected to frequent burial. Whilst they may tolerate days or weeks of being buried, if this is prolonged, their survival is reduced. Hence, populations of *Sabellaria* are often ephemeral.

19A.5.24 *Sabellaria* recruitment is very variable; larvae are thought to take between six weeks and six months to settle and larvae often re-colonise old, dead reefs. The species may therefore be considered highly opportunistic.

19A.5.25 Whilst *Sabellaria* is subjected to, and often is able to colonise due to, natural changes in sediment, reefs are known to have been lost from rising sand levels, as a consequence of the construction of sea walls. However, recovery has also been reported in these instances.

19A.5.26 With the above taken into account, the potential impacts of each of the outfall options are considered below.

Options 1 and 2 (*Sabellaria*)

19A.5.27 The modelled discharges in Option 1, the three outfalls, and Option 2, the single outflow at Location A, each fall short of the *Sabellaria* patches (**Figures 19A.4** and **19A.5**, respectively). These options are therefore considered to be of **low**, predicted magnitude on *Sabellaria*. The value and sensitivity of *Sabellaria* is **medium**, leading overall to a **minor**, adverse impact from each option.

Option 3 (*Sabellaria*)

19A.5.28 Option 3, a single outfall at Location B (HPC drainage ditch), could potentially result in adverse impacts on *Sabellaria* and the magnitude is considered to be **medium**. The value of *Sabellaria* reef is **medium** as it is listed as an Annex I habitat of international importance, designated under the Habitats Directive, yet not deemed highly sensitive to disturbance. Overall, the impact is predicted to be of a **moderate**, adverse impact on *Sabellaria*.

iii. *Corallina*

19A.5.29 As described in 19A.5.12, due to the proximity of *Corallina* to the discharge points and the potential for increased sediment loadings of discharged water to the foreshore from run-off and soil erosion during site preparation works, there is potential for the *Corallina* turf to be smothered by sediment deposition.

19A.5.30 Taking the above assessment into account, the potential effects of sediment deposition on *Corallina* due to each of the three discharge options are identified below.

Option 1 (*Corallina*)

19A.5.31 Option 1: The three outfalls would have the potential to disturb *Corallina* and the habitat that it maintains due to the proximity of the outfalls to extensive, recorded areas of this habitat. As described above, the modelled lateral extent of the discharge of freshwater during a 3.33% AEP event shows that approximately 40% of the total area of *Corallina* would be inundated (**Figure 19A.4**). The impact would be likely, adverse, direct and widespread across the foreshore. However, the areas of foreshore would be subject to normal tidal events that would re-suspend any deposited material, and the estuary already maintains high levels of suspended sediments. Acknowledging that the value of the *Corallina* has been assessed as **medium**, the overall magnitude of the impact is predicted to be **very low**, as the receptor would experience little to no degradation, with any disturbance in the range of natural variability. Consequently, the impact of Option 1 is assessed as **minor**, adverse for this receptor.

Option 2 (*Corallina*)

19A.5.32 The discharge of Option 2, the single outfall at Location A, runs just to the west of the most easterly patch of algal turf (**Figure 19A.5**). It is therefore predicted to be an impact of only **very low** magnitude to the **medium**-value *Corallina*. Overall, a **minor** impact is anticipated.

Option 3 (*Corallina*)

19A.5.33 Option 3, the single outfall at Location B (HPC drainage ditch), would potentially result in adverse impacts on a small area of *Corallina* and the habitat that it maintains, due to the modelled lateral extent of the discharge (**Figure 19A.6**). The impact would be likely, adverse, direct and localised. However, as for Option 1, the areas of foreshore would be subject to normal tidal events that would re-suspend any deposited material and the estuary already maintains high levels of suspended sediments. The overall magnitude of the impact is predicted to be **low**, as the receptor would experience little or no degradation with any disturbance in the range of natural variability. Consequently, the impact of Option 3 is assessed to be **minor,** adverse for this **medium**-value receptor.

iv. Assessment Outcome

19A.5.34 For *Sabellaria*, Options 1 and 2 would bring only minor effects from sediment deposits, yet moderate effects would result from Option 3. For *Corallina*, Option 1 would bring moderate effects from sediment deposits, whereas Options 2 and 3 would have only minor effects. Therefore, the single outfall at Location A (Option 2) would be the best compromise to mitigate impacts of sediment deposits.

d) Effects of Scour

19A.5.35 A further consideration is the potential impact of larger volumes of discharge in terms of the potential physical scour imposed by the flow itself and consequent disturbance of the habitats involved. Peak volume rates expected under a 3.33% AEP event are not so different from those currently estimated for the HPC drainage ditch (20,470m^3, at 13.5m^3.s^{-1}). Given that Option 2 is predicted to have the least impact on the intertidal receptors in terms of sediment deposits and a lesser effect than Option 1 for freshwater discharge, only Option 2 has been considered in this section.

19A.5.36 Additional modelling of Option 2 (the preferred discharge option) was carried out to explore a worst-case scenario. In addition to the 3.33% AEP event, the following volumes were incorporated into the model: pumped groundwater, sewage effluent, tunnel excavation emergency discharge, plus commissioning phase 'cold-flush' treatment (Ref. 19A.1). This resulted in a 3.33% AEP event plus effluent stream flow rate of 13.674m^3.s^{-1}. **Figure 19A.7** illustrates that this worst-case plume for Option 2 and demonstrates no radical difference from the earlier model for Option 2.

19A.5.37 Detailed habitat and biotope mapping is illustrated in **Volume 2, Chapter 19**, **Figures 19.08** to **19.10**. **Figure 19A.8** appended to this appendix illustrates the simulation for Option 2 for the local intertidal area and, for comparison, the estimated discharge pattern associated with the existing HPC drainage ditch. The total intertidal area affected by the Option 2 discharge flow would be approximately 8,170m^2 at the estimated 1 in 30 year freshwater runoff rate. The areas of EUNIS biotopes that would be affected by these same flows would be:

- A1.32: LR.LLR.FVS: Fucoids with variable salinity*:* **1189m^2**;
- A1.322: LR.LLR.FVS.FspiVS: [*Fucus spiralis*] on sheltered variable salinity upper eulittoral rock: **123m^2**;
- A1.323/A1.326: LR.LLR.FVS.FvesVS/FserVS; [*Fucus vesiculosus*] on mid eulittoral variable salinity boulders and stable mixed substrata and/or [*Fucus serratus*] and large [*Mytilus edulis*] on variable salinity lower eulittoral rock: **63m^2**;
- A1.324: LR.LLR.FVS.AscVS [*Ascophyllum nodosum*] and [*Fucus vesiculosus*] on variable salinity mid eulittoral rock: **22m^2**;
- A1.326: LR.LLR.FVS.FserVS: [*Fucus serratus*] and large [*Mytilus edulis*] on variable salinity lower eulittoral rock: **56m^2**;
- A1.46 (MudBed): Variable depth mud and/or sandy mud on flat bedrock, coded as hydrolittoral soft rock: **3658m^{-2}**;
- A2.111: LS.LCS.Sh.BarSh: Barren littoral shingle: **441m^2**;
- A2.431: LR.FLR.Eph.BLitX: Barnacles and [*Littorina* spp.] on unstable eulittoral mixed substrata: **2575m^2**; and
- A2.711: LS.LBR.Sab.Salv: *Sabellaria alveolata* reefs on sand-abraded eulittoral rock: **44m^2**.

19A.5.38 Thus, this discharge route mainly crosses rock substrata which is largely, if not altogether, impervious to scour. The area of mixed substrata is in the mid-intertidal zone and thus is subjected to spring/neap tidal processes of suspension/deposition/ re-suspension and wave influence. In addition, the biotopes described are widespread within the area and typical epifauna and epiflora of rocky shores. The value of the aggregate receptor is therefore considered to be **low** and the magnitude of the impact also **low**. A **minor,** adverse impact is thus anticipated.

19A.6 Overall Conclusion

19A.6.39 Whilst the various outfall options have the potential to cause different adverse effects, depending on biota sensitivity and location, in summary, most effects will be minor. However, Option 1 and Option 3 would have more significant effects than Option 2 on the intertidal habitat.

19A.6.40 Given these results, the outfall site at Location A (Option 2) is proposed as the most favourable site to ensure that impacts on intertidal biota are minimal.

19A.6.41 Other issues, such as the release of ammonia-containing, sanitary, waste effluent and the related biochemical oxygen demand have not been explored in this report. However, the Environment Agency has indicated that the permit will likely be set at the Water Framework Directive environmental quality standard of 21µg.l^{-1} at the point of discharge.

1. Introduction

1.1 Purpose of this Report

EDF Energy is seeking to construct a new nuclear power station (hereafter referred to as ‘Hinkley C’) on land to the west of the existing Hinkley A and B stations. Entec UK Ltd (now part of AMEC Environment and Infrastructure UK Ltd) was appointed to undertake the assessment of the impacts of the proposed Hinkley C development on biodiversity, excluding coastal/marine biodiversity other than birds. This report details the results of habitat surveys that were conducted in 2009, comprising a Phase 1 Habitat survey, hedgerow assessment and woodland condition survey. Relevant previous survey work, undertaken in 2007 and 2008, is also summarised. The results of the detailed vegetation surveys completed using the National Vegetation Classification (NVC) methodology are reported separately.

1.2 Background Information

1.2.1 Survey Area

The boundary of the area within which it is proposed to develop Hinkley C was progressively refined in response to, *inter alia*, engineering and other design requirements, and environmental information. At the time of the habitat surveys that were undertaken in 2009, the area within which it was envisaged that Hinkley C would be located was referred to as the Strategic Siting Area (SSA - see Figure 1.1). The boundary of the SSA was therefore used to define the area for the 2009 habitat surveys; hence all references to the habitat survey area boundary in chapter 11 of the ES relate to the SSA. The SSA boundary includes all the land within the final ‘Construction Boundary’.

1.2.2 Site Description

The majority of the land within the SSA is agricultural, comprising 16 arable fields and 16 grassland fields with various levels of agricultural improvement. The fields are primarily bordered by mature hedgerows. Six small, rectangular broad-leaved woodlands are located within the northern part of the SSA and a square block of young broad-leaved plantation has been created in the central part of the area, with smaller areas of isolated scrub scattered along the northern boundary and in the eastern parts of the SSA. Two watercourses flow west to east through the SSA (further seasonal ditches also occur) and a further watercourse is present on the southern boundary of the SSA. Three ponds occur within the SSA.

The SSA is adjacent to the Bristol Channel. A low cliff, between 0.2m and 10m in height, forms an escarpment between the land and sea.

The land immediately adjacent to the west SSA is similar in character to that within the western part of the SSA, i.e. it comprises agricultural fields (both arable and improved pasture), which are separated by intact species-poor and species-rich hedgerows. A small number of ponds occur and the upper reaches of the Bum Brook flow through the area.

The land east of the SSA is different in character to that within the SSA. It forms part of Bridgwater Bay SSSI and comprises large open fields separated by drains, with very few hedgerows present. The fields immediately adjacent to the SSA have been agricultural improved and are relatively species-poor. However, those fields to the south and east are less intensively grazed and support a more varied sward and have a greater diversity of plant species.

The proposed development falls into the Vale of Taunton and Quantock Fringes Natural Area[1] (English Nature, 1998), which describes the lowland landscape around the major towns of Taunton, Wellington and Minehead between the Quantock Hills, Brendon Hills, Exmoor and the Blackdown Hills. The Natural Area is characterised by a wide variety of habitats and species, including hedgerow and hedgebanks, calcareous grassland, streams, woodland and scrub, nightingale, otter and bats, all of which occur or could occur within the site.

The Natural Area immediately to the east of the site is the Somerset Levels and Moors Natural Area (English Nature, 1997).

[1] The classification of areas of the country into distinct Natural Areas (NAs) was undertaken by English Nature (now Natural England) in order that areas of the countryside identified by unique combinations of physical attributes, wildlife, land use and culture could be grouped together. Overall, 143 NAs, including 24 Coastal NAs have been identified.

2. Methodology

2.1 Methods

2.1.1 Phase 1 Habitat Survey

Distinct habitats within the survey area were identified and mapped based on the Phase 1 habitat ecological survey methodology (JNCC, 2003). Additional information such as the typical plant species composition of the habitat types, whether stock are present or other management information was also recorded where appropriate. Any features considered to be of particular biodiversity interest were subject to a more detailed description in a target note; these have then been incorporated into the main text.

As the standard Phase 1 habitat survey methodology is, in the main, concerned only with vegetation communities, initial surveys (in 2007 and 2008) were extended[2] to allow for the provision of information on other ecological features, particularly to identify the presence/potential presence of legally protected species, such as bats, badgers and water voles. This was not a necessary component of the 2009 Phase 1 habitat survey (which covered the entire SSA and was undertaken on the 12, 13 and 21 May and 03 June 2009 by Gemma Lee MIEEM), given that the requirement for protected species surveys had already been identified.

2.1.2 River Corridor Survey

A river corridor survey was completed for each watercourse within the SSA following the guidance provided in the River Corridor Surveys - Conservation Technical Handbook (NRA, 1992). Each watercourse was surveyed on the 20 July 2009. During the survey, information on the physical and biological features of the channel were recorded within the aquatic, marginal, bank and adjacent land zones in order to characterise the watercourse. The river corridor survey allows a more detailed survey to record the plant species present within and adjacent to the channel and also highlights culverts, bridges and other channel features.

The output of the survey is a series of maps illustrating the course of the channel, the habitat types within and adjacent to the channel and the dominant plant species. The Key to the maps produced is included in Appendix A.

2.1.3 Hedgerow Assessment

All hedgerows considered to be at least 30 years old within the SSA were assessed against '*The Hedgerows Regulations 1997*'. Therefore, for each hedgerow a 30m section (per every 100m of hedgerow) was surveyed and the following information recorded on a standard Entec pro-forma:

- site information (including a grid reference);
- hedgerow dimensions (i.e. Height, width and length);

[2] Institute of Environmental Assessment (1995) *Guidelines for Ecological Assessment* Chapman and Hall

- number of woody species;
- hedgerow features (including ditches, banks and standard trees);
- number of connections to other hedgerows, woodlands or ponds; and
- ground flora plant species.

A photo was also taken of every hedgerow surveyed. For hedgerows over 100m long (where more than one 30m section was surveyed), an average of the number of woody species was taken.

The Regulations provide criteria against which the historical and ecological importance of hedges can be assessed. During this survey only the ecological importance was assessed, not the archaeological importance which also forms part of the Hedgerow Regulations. For a hedgerow to be classified as being ecologically important it must meet at least one of the following criteria:

- contains at least seven woody species in a 30m stretch; or
- at least six woody species in a 30m stretch and at least three features; or
- at least six woody species in a 30m stretch and the presence of native black poplar (*populus nigra*), small leaved lime (*tilia cordata*), large leaved lime (*tilia platyphyllos*) and wild service tree (*sorbus torminalis*); or
- at least five woody species in a 30m stretch and four features; or
- if adjacent to a bridleway or footpath at least four woody species in a 30 m stretch and three features.

Features referred to above include the following:

- a bank or wall along at least half the length of the hedge;
- an intact hedge;
- one standard tree per 50m of length;
- three valuable ground flora species (as defined in the regulations);
- a ditch along at least half the length of the hedgerow;
- good connections with other hedgerows; and
- a parallel hedge within 15m.

Using the information gathered, it has been determined which hedgerows should be considered as ecologically important under The Hedgerow Regulations.

2.1.4 Woodland Condition Survey

In order to characterise the woodlands within the SSA, in more detail than is possible under the Phase 1 habitat survey methodology, a woodland condition survey was completed. There is no standard methodology or guidance available for this type of survey. However, as the ultimate aim of the survey is to provide information to determine the biodiversity value of the woodlands, the assessment criteria within the Guidelines for the Selection of Biological SSSIs (Chapter 2 Woodlands, JNCC, 2006) have been used a framework for the data collection.

The broad assessment criteria from this document are as follows:

- diversity;
- naturalness;
- rarity;
- size;
- ecological position;
- potential value;
- representativeness; and
- fragility.

In order to investigate the value of the woodlands against the criteria listed above, information (based on the field measures of the Nature Conservation Review criteria for British Woodlands contained within the Guidelines for Selection of Biological SSSI) was collected for each woodland through a desk study and field survey.

Hence, the Ordnance Survey basemap was used to calculate the area of each woodland. Whether the woodlands are listed on the Ancient Woodland Inventory (and therefore have been in existence prior to 1600AD) was determined using the Multi-Agency Geographical Information for Countryside website (www.magic.gov.uk). Historical maps from the website http://www.old-maps.co.uk, were then used to investigate whether those woodlands not on the Ancient Woodland Inventory were, nevertheless, present between 1887 and 1904.

During the field surveys, a detailed list of the plant species present within the ground flora, understorey and canopy layers of the woodland was compiled, with notes on dominant species also taken. This information has been used to compare the woodland plant communities present within the SSA with those described in the woodland section of the National Vegetation Classification (NVC) (Rodwell, 1991) to determine how typical, diverse and natural the woods are. Information regarding the structure of the woodland, whether the wood supports any other habitat types and the classification of the adjacent land use was also recorded.

Any evidence of historical or recent woodland management was also recorded during the field surveys. For those woodlands managed by British Energy[3], this information was augmented with information from the yearly land management reports, which record the management that has been completed.

[3] British Energy became part of EDF Energy in 2009

3. Results

3.1 Phase 1 Habitat Survey

The location of the various habitats recorded during the 2009 survey is shown on the Phase 1 Habitat map in Figure 3.1. A description of the habitat types present within the SSA is provided below.

3.1.1 Arable

As described in section 1.2.2, half the agricultural fields within the SSA are currently being used for arable crop production. Most of these fields have been sown with grain crops (such as wheat and corn), but a few have been sown with grass seed and mown for silage. All of the fields are intensively managed with very small or no field margins. Plant species recorded around the edges of the fields typically include species that are tolerant of disturbance such as common fumitory (*Fumaria officinalis*), scented mayweed (*Matricaria recutita*), scarlet pimpernel (*Anagallis arvensis* subsp. *Arvensis*), common poppy (*Papaver rhoeas*), knotgrass (*Polygonum aviculare*) and common field-speedwell (*Veronica persica*).

3.1.2 Grassland

Improved and Poor Semi-Improved

Approximately half of the agricultural fields within the SSA comprise improved or poor semi-improved grassland.

The improved fields (around the Power Station external car park and adjacent to the central watercourse) are currently (or have previously) been grazed by cattle and are dominated by perennial rye grass (*Lolium perenne*) with white clover (*Trifolium repens*), cock's-foot (*Dactylis glomerata*), meadow foxtail (*Alopecurus pratensis*), shepherd's-purse (*Capsella bursa-pastoris*) and common chickweed (*Stellaria media*). In some of the fields the sward is more structurally diverse and supports a greater range of species such as creeping cinquefoil (*Potentilla reptans*), bulbous buttercup (*Ranunculus bulbosus*) and meadow vetchling (*Lathyrus pratensis*) (TN1).

There are three areas of poor semi-improved grassland within the SSA. In the northern part of the site three fields are within an environmental stewardship scheme and are being managed to encourage reversion to calcareous grassland (TN2). At present, however, these fields support few species indicative of calcareous grassland. Instead, they are dominated by grasses, particularly meadow foxtail, false-oat grass (*Arrhenatherum elatius*), tall fescue (*Festuca arundinacea*) and rough meadow grass (*Poa trivialis*) with common herbs such as hop trefoil (*Trifolium campestre*), red clover (*Trifolium medium)*, ground ivy (*Glechoma hederacea*) and common vetch (*Vicia sativa* subsp. *segetalis*). The presence of glaucous sedge (*Carex flacca*) suggests the early stages of reversion to a more species-rich, calcareous sward.

A further field (Pixies Mound Field - TN3) is also being managed to encourage a more diverse and calcareous influenced sward. However, as with the fields by the coast, a limited number of indicative calcareous species are present including yellow oat-grass (*Trisetum flavescens)* and common centaury (*Centaurium erythraea*). Much of the vegetation is instead dominated by teasel (*Dipsacus fullonum*) and, where rabbit grazing is high, ground ivy and selfheal (*Prunella vulgaris*). A more detailed description of this vegetation community is provided in the Hinkley National Vegetation Classification Report (Entec, 2007).

Two fields adjacent to the watercourse (TN4) located in the centre of the SSA are also considered to support poor semi-improved grassland. Due to the location of the fields in the valley, they support some wetland plant species rather than the calcareous species found in other areas of the site. The fields are again dominated by grasses, primarily meadow foxtail, Yorkshire fog (*Holcus lanatus*) and cock's-foot (*Dactylis glomerata)* with small amounts of marsh foxtail (*Alopecurus geniculatus*) and red fescue (*Festuca rubra*). Hard rush (*Juncus inflexus*), jointed rush (*Juncus articulatus*) and false fox-sedge (*Carex otrubae*) are also present with abundant meadow buttercup (*Ranunculus acris*) and cuckooflower (*Cardamine pratensis*).

Semi-Improved Calcareous

There are four main areas of calcareous grassland within the SSA. These are located along the coastal strip (TN5), within two small fields adjacent to the coast (TN6), to the east of Pixies Mound and Branland Copse (TN7) and around the Sewage Treatment Works (STW) (TN8). The first two areas are described in more detail in the Hinkley National Vegetation Classification Report (Entec, 2007), whilst the third and fourth areas are described in the Hinkley National Vegetation Classification Report 2009 (Entec, 2009).

The calcareous grassland along the coast (TN5) occurs in a linear strip between the cliffs and agricultural fields to the south. Much of the grassland supports a range of common species including cleavers (*Galium aparine*), teasel, selfheal and hairy bitter-cress (*Cardamine hirsuta*). Pyramidal orchid (*Anacamptis pyramidalis*), wild carrot (*Daucus carota*) and agrimony (*Agrimonia eupatoria*) are common in these areas with infrequent bee orchid (*Ophrys apifera*) and grass vetchling (*Lathyrus nissolia*). A small area (near an information/interpretation sign) supports a lower growing sward and species indicative of calcareous grassland including yellow-wort (*Blackstonia perfoliata*), carline thistle (*Carlina vulgaris*), salad burnet (*Sanguisorba minor*) and common birds-foot trefoil (*Lotus corniculatus*).

The grassland at TN6 is dominated by the grasses creeping bent (*Agrostis stolonifera*), cock's-foot, red fescue, common bent (*Agrostis capillaries*) and crested dog's-tail (*Cynosurus cristatus*), but also supports a wide range of herbs commonly found on calcareous substrates including agrimony, glaucous sedge, yellow-wort, burnet-saxifrage(*Pimpinella saxifrage*) grass vetchling and dyers greenweed (*Genista tinctoria*) also occur.

To the south of the existing Power Station (TN7), calcareous grassland occurs in small pockets of sloping ground between areas of scrub. The sward is short due to rabbit grazing and supports a wide of grass and herb species including early dog-violet (*Viola reichenbachiana*), creeping cinquefoil, perforate St. Johns-wort (*Hypericum perforatum*), yarrow (*Achillea millefolium*), agrimony and fern grass (*Catapodium rigidum*).

The composition of the calcareous grassland around the STW is similar in composition to the area indicated by TN7, although it is slightly less diverse, with a greater degree of dominance of grasses such as Yorkshire fog and common couch (*Elytrigia repens*). Herbs recorded include primrose (*Primula vulgaris*), yarrow, creeping cinquefoil, common knapweed (*Centaurea nigra*) and common bird's-foot trefoil.

3.1.3 Woodland and Scrub

Woodland

Seven areas of semi-natural broad-leaved woodland occur within the coastal part of the SSA. All support an open canopy of mature trees with a dense scrub understorey. These semi-natural woodlands are described in more detail in section 3.3.

Within the SSA areas of plantation woodland also occur and these are described in more detail below.

In the southern part of the SSA there are two areas of broad-leaved plantation woodland. The larger of these is known as Bishop's Wood (TN9) and was planted in winter 1998/1999. Hawthorn (*Crataegus monogyna*), sycamore (*Acer pseudoplatanus*), hazel (*Corylus avellana*), wild privet (*Ligustrum vulgare*), dogwood (*Cornus sanguinea*) and downy birch (*Betula pubescens*) have been planted and are around 2-3m tall. Underneath the open canopy the ground flora is relatively species-rich supporting cowslip (*Primula veris*), common vetch, imperforate St John's-wort (*Hypericum maculatum*), common bird's-foot trefoil and hedge woundwort (*Stachys sylvatica*). The smaller area of plantation woodland (TN10) has been planted with a similar range of native broad-leaved species. However, tall ruderal vegetation, such as nettle (*Urtica dioica*) and creeping thistle (*Cirsium arvense*), dominates the ground flora.

Two further areas of mature broad-leaved plantation woodland occur along the eastern edge of the Power Station security fence and along Bum Brook.

Scrub

Patches of scrub occur mainly in the eastern and northern areas of the SSA, often in mosaics with semi-improved calcareous grassland.

An extensive area of scattered and dense scrub, approximately 40m by 15m, is located to the south of the existing Power Station (TN7). The commonest scrub species within this area are bramble (*Rubus fruticosus agg.*), blackthorn (*Prunus spinosa*) and hawthorn, with dogwood, elder (*Sambucus nigra*) and hazel less frequent. Around the STW similar species have been planted.

A dense area of European gorse (*Ulex europaeus*) also occurs on a slope in one of the improved fields to the west of the Hinkley B Training buildings (TN11). This area has reduced in size since 2007 due to management to control its spread.

Along the coastal strip, scattered areas of dense scrub occur between the coast path and the cliff. These areas comprise a range of relatively low growing (due to the prevailing wind) species including dogwood, blackthorn and hawthorn.

3.1.4 Water Features

Watercourses

Two watercourses occur within the SSA (TN12 and TN13). The results of the River Corridor Survey for the watercourse at TN12 are presented in Appendix B and for the watercourse at TN13 in Appendix C.

Two further watercourses are present on the southern boundary of the SSA (TN14 and TN15).

Watercourse at TN12

The first watercourse within the site (TN12) issues at ST197456 within the SSA boundary, flowing east, then north through Whitewall Brake (broad-leaved woodland, ST202460) and into the sea at ST202461. It is approximately 1km in length and varies in width between 0.5m and 1m. The watercourse passes through three culverts.

The banks are steep (up to approximately 80cm tall) from the origin of the watercourse to Whitewall Brake, from where the channel appears to have been re-profiled and the banks are shallower (around a 45^o slope). The banks consist of earth throughout. Approximately 70% of the stream bed has a muddy substrate, whilst in Whitewall Brake gravel predominates. The north-eastern section is culverted under a farm track and footpath (for approximately 3m) into Whitewall Brake. This part of the watercourse has sparse bank-side and channel vegetation limited to fool's water-cress (*Apium nodiflorum*), hemlock water-dropwort (*Oenanthe crocata*) and bramble. The stream exits the wood and percolates through the unconsolidated rocky shore to the sea.

This watercourse tends to have a steady flow of water estimated at ~20-30cm deep during the wetter, winter months. However, sections of the watercourse dry out completely in the summer and autumn, particularly the section upstream from Whitewall Brake. The water level of the stream within Whitewall Brake was estimated at 10cm during May 2009. The banks support a range of ruderal and marginal species, which quickly shade the water in the summer. Species present include bramble, creeping thistle, great willowherb (*Epilobium hirsutum*), nettle, hemlock (*Conium maculatum*), hemp-agrimony (*Eupatorium cannabinum*), water figwort (*Scrophularia auriculata*) and fool's water-cress. The mature trees within Whitewall Brake, including crack willow (*Salix fragilis*) and hawthorn, also shade this section of the watercourse throughout the year.

Watercourse at TN13

This watercourse is approximately 1km in length and flows west to east across the centre of the SSA before joining with the drains on Wick Moor underneath the Power Station entrance road. The watercourse is between 0.5m and 1m wide and varies in depth between 0.1m and 1m. The watercourse passes through five culverts and under one stone bridge.

The far western section of the watercourse appears to be dry in most years as it currently supports fairly well established grassland and ruderal vegetation including nettle, false oat-grass (*Arrhenatherum elatius*) and broad-leaved dock (*Rumex obtusifolius*), and probably only holds water in very heavy and prolonged rain.

The central section of the watercourse is located within an improved grassland field grazed by cattle. Because of this, the banks are very poached and disturbed and support a limited range of species, with only small amounts of creeping thistle, hard rush, false fox-sedge, creeping buttercup (*Ranunculus repens*) and cocksfoot on the bank and fool's-watercress and brooklime (*Veronica beccabunga*) present in the channel. The base of the watercourse in this section is silt and mud, which combined with the cattle disturbance, results in limited water clarity. This section of the watercourse dried out significantly between May 2009 and July 2009, such that it no longer flowed and only pools of water were present. A small number of scattered hawthorn, dog-rose (*Rosa canina*) and bramble bushes line the shallow banks (~100cm in height) of the watercourse in this location.

The eastern section of the watercourse forms a boundary between the fields north and south of it. These are also grazed by cattle but at present the poaching is less severe (than the central section) and only on one side of the bank (hedgerows prevent cattle access to both sides). This section also appears to have been dredged in 2007 or 2008 with the arisings left on the adjacent banks (which are characterised by a ruderal community dominated by creeping thistle). The watercourse here is bounded by a dense hedgerow west of the road which becomes a line of scrub towards the central section. Vegetation beneath the hedgerow is sparse and the earth at the base is compacted. The bank underneath the hedge is approximately 20cm tall. The bank opposite the hedgerow is generally species-rich, supporting a range of ruderals and grasses including meadowsweet (*Filipendula ulmaria*), hard rush, reed sweet-grass (*Glyceria maxima*), false oat-grass and hemlock water-dropwort. Within the channel, common reed (*Phragmites australis*) is locally dominant (up to 20% cover) and duckweed (*Lemna minor*) covers up to 95% of the water surface. Common starwort (*Stellaria media*) occurs with duckweed and covers approximately 5% of the water surface. Water crowfoot (*Ranunculus aquatilis*) also occurs in dense sub-merged patches where the water is deeper. Water forget-me-not (*Myosotis scorpioides*), brooklime and creeping buttercup also occur within the channel.

Watercourse at TN14

This watercourse is ~1m wide and has steep earth banks up to 70cm in height. The bed of the watercourse is predominantly muddy, with vegetated mud platforms at the base of the banks.

This watercourse has a steady flow of water. An estimated 70cm of water was present during March 2007, but the western section dries up during the summer.

The east section, around the Sewage Treatment Works retains water throughout the year and is dominated by common reed and duckweed with few other species present. The banks are approximately 40-50cm tall on the north side and ~30cm tall on the south side with some sections being heavily poached by cattle from the adjacent fields.

The west section is bounded on the north side by scrub woodland and the substrate is predominantly decaying leaf litter. The northern bank is approximately 20cm tall and the southern bank is 40-50cm tall. The southern bank supports a wide range of ruderal and grass species including false oat grass, purple loosestrife (*Lythrum salicaria*), bramble, nettle, hemlock and fleabane (*Pulicaria dysenterica*). Duckweed covers approximately 85% of the water surface and water-plantain (*Alisma plantago-aquatica*) also occurs.

Watercourse at TN15

This watercourse comprises the Bum Brook and Bayley's Brook, which join adjacent to the SSA and then separate near to Stolford into the West Brook and East Brook. The watercourse varies in width and depth, but along most of the area adjacent to the SSA it is approximately 1m wide and 30-50cm deep.

The watercourse flows east from Pond 8 (Hinkley Great Crested Newt Report, Entec, 2009) located on Benhole Lane, and forms a field boundary between arable and pasture fields. The watercourse is very shaded in this section due to the extensive bank vegetation, which includes bramble, nettle, Himalayan balsam (*Impatiens glandulifera*) and great willowherb with overhanging semi-mature crack-willow trees. The banks comprise earth in this location and are ~70cm tall. The water clarity is poor, but the flow is fairly fast. At ST 203445, the Bum Brook joins Bayley's Brook underneath a concrete footbridge.

To the east of this (downstream) there are no trees and scrub on the banks. Instead the banks are vegetated by rough grassland, hence this section is not shaded. The banks are taller in this Section, being between 60cm and 80cm tall, and are a mixture of earth and stone. One bend in the watercourse has been reinforced with a stone wall. The water flow here continues to be fairly fast and the water clarity is good. The base substrate is a mixture of silt and pebbles. Species recorded on the banks include cow parsley (*Anthriscus sylvestris*) and hemlock water-dropwort. Branched bur-reed (*Sparganium erectum*) and fools water-cress occur within the channel. Further downstream, a hedgerow is present on the southern side of the watercourse which again shades the channel.

Water Bodies

There are three water bodies within the SSA (TN16, TN17 and TN18). Further ponds occur within 500m of the SSA. These are described in more detail within the Hinkley Great Crested Newt Report, 2009 (Entec, 2009).

Water Body at TN16

This pond (known as Pixies Pond) is ~12m long by ~8m wide. In 2007 common reed covered an estimated 75% of the water surface with an area of open water in the centre, but clearance in 2008 reduced the common reed cover to 40%. The banks are reinforced using wooden stakes on the northern side and are shallow (~10cm) around the rest of the perimeter. Bulrush (*Typha latifolia*), meadowsweet, marsh-marigold (*Caltha palustris*) and water mint (*Mentha aquatica*) occur around the edges of the pond. The pond is surrounded by a small strip of grassland and scrub.

Water Body at TN17

This water body is a large pond (~15m x 15m) that is approximately 60% vegetated by common reed with only 40% of the pond surface being open water. Plant species diversity is limited due to the dominance of common reed with small amounts of bittersweet (*Solanum dulcamara*) and great willowherb present. The water body is in excess of 1m deep (actual depth could not be determined due to the dense common reed around the pond preventing safe access) and the water clarity is poor. The pond has very shallow margins around the edges without proper banks. The northern and western edges of the water body have overhanging crack willow trees creating some shading.

Water Body at TN18

This pond is located within a hedgerow boundary adjacent to an arable field. The pond has a mixture of willow and hawthorn growing in the centre, the bases of which are currently submerged, which suggest the pond is prone to drying out regularly and in July 2009 the pond was dry. There are very few aquatic or marginal broad-leaved plants and although there are areas of open water, the pond is 90% shaded from the surrounding scrub and hedgerows. The pond is approximately 20m by 8m in size.

3.1.5 Other Habitat Types

Cliff Vegetation

The northern boundary of the SSA comprises a chalk maritime cliff. The top of the cliff and the ledges on the vertical northern face are vegetated by calcareous grassland and scrub (described above). In most places along the edge of the SSA, the high tide line is the bottom of the cliff and therefore marks where the inter-tidal area begins (which is outside the scope of the terrestrial ecology surveys). In a small number of locations there is some vegetation at the base of the cliff.

The eastern end of the cliff (nearest the Power Station - TN 19) is short in height (between 0.4-2m) and has been reinforced with gabions. The high tide strand line is located approximately 2-3m from the base of the cliff. In-between the cliff base and the high tide mark a small number of plants are growing most of which have colonised from the surrounding rough grassland including curled dock (*Rumex crispus*), hogweed (*Heracleum sphondylium*) and cow parsley, with sea-beet (*Beta vulgaris ssp. maritima*) being the only species that is typically found along the strand line.

Between 20-30m west of TN19 the cliff increases in height and remains relatively high along the rest of the SSA boundary, varying in height between 3-10m. The cliff face is vertical and flat and along the majority of the section adjacent to the SSA there are few locations that vegetation could colonise due to the lack of soil. However, where ledges do occur or there have been slippages some vegetation is present.

This vegetation is relatively species-rich and is very similar in composition to the calcareous grassland present along the cliff top. Grasses and ruderal species tend to dominate the vegetated areas with cock's-foot, red fescue and annual meadow-grass abundant. Teasel is also abundant with oil-seed rape (*Brassica napus* subsp. *Oleifera*), ribwort plantain (*Plantago lanceolata*) and bramble common. Low growing herbs are less frequent, but salad burnet, carline thistle, ground ivy, common bird's-foot trefoil and scarlet pimpernel are also present. Species present which occur less frequently (only noted in one or two locations) include dog-rose, stinking iris (*Iris foetidissima*), bittersweet and wild carrot.

With the exception of the area at TN19, the high tide mark is located at the base of the maritime cliff. Therefore, along the vast majority of the cliff adjacent to the site there is no terrestrial vegetation present (because this area is very regularly inundated by sea water).

Tall Ruderal

Small areas of tall ruderal vegetation occur within the SSA. These are often associated with the hedgerow bases, but have not been mapped on Figure 3.1 due to their small size. Species frequently present include nettle, bramble and hemlock. Two areas of tall ruderal vegetation, supporting nettle, creeping thistle and bristly ox-tongue (*Picris echioides*), also occur on the bunds around the edge of the external Power Station car park (TN20).

Swamp

A small area of swamp vegetation occurs to the east of the STW (TN21). This is dominated by common reed, with encroaching scrub. The ground is only seasonally wet.

3.2 Hedgerow Assessment

Within the SSA most of the boundaries are marked by hedgerows, with a few fence lines in the northern area. The hedgerows vary in quality from single-species and heavily managed to relatively unmanaged and species-rich.

Table 3.1 lists every hedgerow surveyed within the SSA and highlights whether it is considered to be ecologically 'important' under the Hedgerow Regulations. If a hedgerow is 'important' the reason why this conclusion has been reached is stated. Appendix D contains all the hedgerow survey pro-forma which details the characteristics of each hedgerow. The location of each hedgerow is shown on Figure 3.2.

Hawthorn and blackthorn are the commonest hedgerow species within the SSA. Field maple (*Acer campestre*), English elm (*Ulmus procera*), dogwood, dog-rose and field-rose (*Rosa arvensis*), wild privet and hazel are also frequently present. Many hedgerows also contain a small number of elder, ash (*Fraxinus excelsior*), wayfaring tree (*Viburnum lantana*) and spindle (*Euonymus europaeus*). Willow, oak (*Quercus* sp.) and gorse (*Ulex europaeus*) are present only rarely.

The ground flora associated with all the hedgerows surveyed is species-poor and generally contains few of the species notable under the Hedgerow Regulations. Of these notable species lords-and-ladies (*Arum maculatum*), wood false-brome (*Brachypodium sylvaticum),* herb-Robert (*Geranium robertianum*) and early dog-violet were recorded. The remaining species present; nettle, bramble, false oat-grass and cow parsley, are ruderal and indicative of the agricultural improvement of the surrounding land.

Many of the hedgerows within the SSA are located on banks or adjacent to ditches or both, but few of the hedgerows contain standard trees. Most of the hedgerows are also intact, with less then 10% gaps along their length, which is likely to be due to management completed by landowners within the SSA (i.e. laying and replanting).

3.3 Woodland Condition Survey

Each of the semi-natural broad-leaved woodlands present within the SSA is described below and their locations are shown in Figure 3.3. A summary of the woodland features is provided in Table 3.2 at the end of this section.

3.3.1 Woodland A (Newclose Covert)

Woodland A is located on a gentle south to north upward slope and is partly sheltered from the prevailing wind by the slope to the north. It is surrounded on all sides by agricultural fields (both pasture and arable). Three hedgerows join the wood, providing some ecological linkage to the wider area.

Whilst the woodland is shown as extant in 1887, all four of its boundaries are marked by remnant hedge banks suggesting it may have previously a field. The hedge banks support primarily hawthorn and field maple (which show evidence of previous hedgerow management through laying), with occasional blackthorn and crab apple (*Malus sylvestris*).

The interior of the woodland is fairly uniform, comprising abundant ash of similar age and structure. Many of the ash trees are approximately 10-15m tall with straight vertical stems, although a number are older and there is evidence that some have been coppiced in the past. A small number of mature oak trees are also present. A number of the ash trees have woodpecker holes and signs of rotten branches and/or trunks. Dead trees have been left *in-situ* within the woodland.

The understorey is sparse and predominantly comprises elder with ash and English elm re-growth. In the northern and south-western parts of the woodland there are fewer mature trees and the understorey comprises dense patches of wild privet with small numbers of dogwood and spindle plants.

The ground flora is impoverished, despite light reaching the ground through the patchy canopy, and is dominated by extensive ivy cover and large dense patches of nettle. Other ground flora species recorded include wood false-brome, wild madder (*Rubia peregrine*), pendulous sedge (*Carex pendula*), enchanter's nightshade (*Circaea lutetiana*), cow parsley and spear thistle (*Cirsium vulgare*).

Whilst the woodland appears to have been managed historically, there is no evidence of recent management. The wood is currently used as shelter for game bird rearing.

3.3.2 Woodland B (Haysgrove Brake)

Similar to Woodland A, Woodland B is located on a gentle north to south upward slope. It is surrounded on all sides by agricultural fields (both pasture and arable) and one hedgerow joins the wood. A ditch is present to the north of the wood, although it only holds water intermittently. Woodland E lies adjacent to the northern edge of Woodland B.

The central part of Woodland B is dominated by English elm trees, all of which comprise tall (~8-10m), thin trunks with few horizontal branches. The trunks are relatively close together and during the summer the elm canopies greatly reduce the amount of light reaching the ground flora. Where elms dominate the canopy of the woodland few understorey species occur, mainly limited to occasional elder. In the south-west corner of the woodland a number of dead elms are present.

The south and west boundaries of the wood appear to comprise remnant hedgerows on banks adjacent to dry ditches. This combined with the information from historical OS maps suggests the woodland may have previously been a field that was encroached by scrub, which has later developed into broad-leaved woodland. Hawthorn and field maple are the commonest species growing on the hedge banks, with occasional dogwood, blackthorn and elder. A second line of hawthorn and blackthorn is present along the outside of the western boundary. The plants here appear to be younger and may have been planted at a later date than the hedge banks.

The eastern edge of the woodland also supports a number of mature field maple and hawthorn trees. Several mature field maples and oak trees also occur along the northern edge of Woodland B, adjacent to the ditch.

Ivy dominates the ground flora throughout the woodland. Where light does reach the ground a slightly more diverse woodland flora is present including hart's-tongue fern (*Asplenium scolopendrium*), hedge woundwort, stinking iris, lord's-and-ladies, herb Robert, ground ivy and soft-shield fern (*Polystichum setiferum*) . Large patches of dense nettle and occasional bramble thickets also occur.

This woodland supports a large main badger sett and as a result many pathways and areas of bare ground occur around the sett in the centre of the wood.

No evidence of historical management was observed within the woodland (e.g. coppicing). However, the woodland has been managed fairly recently as a proportion of the elm trees in the southern part of the wood have been felled and left in small linear stacks between the remaining trees.

3.3.3 Woodland C (Seaberton Brake)

Woodland C is located on a gentle north to south upward slope and is surrounded on all sides by agricultural land (both arable and pasture). A public footpath is present along the south and west outside edges of the woodland. The footpath is bounded by a mature hedgerow on the opposite from the woodland. This hedgerow is parallel to the woodland on the south and west sides. No other hedgerows join the woodland.

A clear bank with mature trees is present along the eastern edge of the wood. Field maple and ash are the predominant species and many comprise several stems, which indicates they have at one time been coppiced.

The interior of the woodland supports few mature trees, limited to scattered mature field maple many of which are located in the centre of the wood. The remainder of the woodland canopy comprises tall, leggy hawthorn and blackthorn trees. Elder also forms part of the canopy in places, although it is more generally restricted to the understorey. Wild privet is locally dominant in the understorey, whilst spindle only occurs along the southern boundary of the wood. A small number of semi-mature pedunculate oak (*Quercus robur*) trees are also present.

The ground flora in Woodland C is dominated by ivy and dense patches of nettle. Stinking iris, lord's-and-ladies, hart's-tongue fern and ground ivy occur regularly in small numbers. At the western edge of the wood the canopy is more open and the ground is slightly more diverse with creeping buttercup, cleavers (*Galium aparine*), wood false brome and field forget-me-not (*Myosotis arvensis*) present.

Woodland C falls within the Hinkley County Wildlife Site and is actively managed by EDF Energy. Recent management of the woodland has included replanting species such as ash within the centre of the wood and clearing dense scrub to create glades where more direct sunlight can reach the ground. The current woodland structure reflects this management such that there are alternate areas of dense scrub and glades, cleared of scrub, present in an east-west orientation through the central part of the wood.

3.3.4 Woodland D (Whitewall Brake)

Woodland D is located adjacent to the coastal strip on flat land, with pasture present on the remaining three sides. An unnamed watercourse flows through the centre of the woodland and discharges to the rocky shore to the north. Two hedgerows link to the southern part of the woodland.

The woodland is very different in character on each side of the watercourse. To the west of the watercourse the wood is dominated by English elm, goat willow (*Salix caprea*) and crack willow. The canopy is relatively open (as many of the elms are dead or diseased), but the shrub layer is restricted to occasional elder. The ground conditions are wet in this area with the frequency of pendulous sedge reflecting this. Nettle, hart's-tongue fern and bramble are also abundant.

The woodland to the east side of the watercourse predominantly comprises mature pedunculate oak and field maple with areas of dense hawthorn, blackthorn and holly (*Ilex aquifolium*). Elder and hazel are frequent in the understorey and ash is occasional in the canopy layer. The ground flora is relatively species-rich (when compared to the other woodlands within the SSA) and supports stinking iris, lord's-and-ladies, hart's-tongue fern, male-fern (*Dryopteris filix-mas*), enchanter's nightshade and wood false-brome.

The woodland to the east side of the watercourse can also be divided into three areas. The southern area has been subject to recent management (see below) and comprises a mixture of mature trees and clearings. The central area comprises predominantly mature oak and field maple with a relatively sparse understorey and a ground flora dominated by ivy and hart's-tongue fern with frequent clumps of male-fern. The northern area (closest to the coast) consists of dense hawthorn and blackthorn bushes with occasional holly and no mature trees.

There is evidence of both historical and more recent management in Woodland D. A number of the older hazel and field maple trees appear to have been coppiced previously, but not recently. British Energy undertook management more recently in the south-eastern part of the wood by removing dead elms in an area ~10m by 20m and replanting it with young oak trees. This area is currently dominated by nettle, bramble and elder. A further smaller area was cleared at the southern edge of the wood in 2008 and is allowing more light to reach the ground flora.

3.3.5 Woodland E

Located adjacent to and north of Woodland B, Woodland E is small and triangular. It is situated on flat ground bounded by a small unnamed watercourse to the south (separating Woodland E from Woodland B). On the remaining sides of the wood lie arable and pasture fields.

The northern boundary of Woodland E is marked by a steep bank supporting mature field maple, hazel, blackthorn and a single pedunculate oak tree. Hazel trees also occur along the southern boundary of the woodland with crack willow present along the watercourse.

The ground flora is very similar to other woodlands in the area, being dominated by ivy, with hart's-tongue fern abundant along the edges of the watercourse. Also present is hedge bedstraw (*Galium mollugo*), wood false-brome, common vetch, creeping thistle, nettle and hemlock water-dropwort.

All the hazel trees within Woodland E have been coppiced in the past. More recently the woodland has been used a cover to raise pheasants but active management does not appear to have been undertaken in last few years.

3.3.6 Woodland F

Woodland F is similar to Woodland E in size and location as it is also situated on flat ground and is bounded to the south by the same unnamed watercourse.

Whilst this area is shown as broad-leaved woodland on the historical Ordnance Survey maps, it does not currently support any mature trees, suggesting that it may have been felled since 1904. At present the woodland appears to have originated as a result of the surrounding hedgerows encroaching into this triangle of land. The dominant species is English elm, which forms the canopy layer, although most of the trees are either dead or diseased. Hawthorn and blackthorn form quite a dense understory and the ground flora is dominated by ivy.

3.3.7 Woodland G (Govetts Copse)

Woodland G is located on a gentle north to south upward slope. Along the southern boundary of the woodland is a public footpath with a dense mature hedgerow and arable fields beyond. Improved grassland pasture is present to the west and east of the wood. The northern boundary is adjacent to a track between fields and also the edge of the Power Station external car park.

The woodland supports few mature canopy trees limited to five ash trees, with a maximum of two trunks per tree and around 12 large, mature hawthorn trees. The understorey is relatively species-rich and dense comprising hawthorn, field maple, wild privet, elder and dogwood, with occasional spindle. Where there are gaps in the understorey and more light reaches the ground, nettle dominates the ground flora. Elsewhere, ivy dominates the ground flora with abundant cleavers, frequent stinking iris, lord's-and-ladies, wood false-brome and ground ivy, and occasional hairy bittercress and ground ivy.

A remnant hedge bank is present along the western boundary of the woodland upon which two of the mature ash trees are located. West of the hedge bank two rows of mature, planted broad-leaved scrub are present, comprising hawthorn, blackthorn, field maple, elder and dogwood.

There is no evidence of historical management of the woodland apparent. However, it was managed by British Energy in recent years, including the clearance and replanting of field maple within the understorey in the northern section, which has resulted in a more diverse ground flora.

3.3.8 Woodland H (Branland Copse)

Woodland H is located on flat ground adjacent to the electricity substation that is part of the existing Power Station complex. The woodland is bounded to the north and west by the power station access road and to the east by the substation. At the southern boundary of the woodland is a poor semi-improved grassland field (Pixies Mound). The south-eastern corner of the wood grades into a scrub and grassland habitat mosaic.

This woodland is characterised by a mature canopy layer comprising pedunculate oak, ash and field maple. Five Monterey pine (*Pinus radiata*) trees also occur in the north-east corner of the woodland. A number of banks and associated ditches occur within the woodland and the mature ash trees are often located upon these banks. Many of the mature trees (particularly ash) have woodpecker holes or broken and rotting branches.

The understorey in the centre of the wood is generally open and relatively diverse with elder, hawthorn and holly frequent, and English elm, hazel and spindle occasionally present. The understorey species create a denser area around the edges of the woodland where there are fewer mature trees creating shade.

The ground flora is dominated by ivy with frequent lord’s-and-ladies, hart’s-tongue fern and stinking iris. Small areas are more species-rich supporting ground ivy, primrose and early purple orchid. Nettle and broad-leaved dock are also frequent in the ground flora.

A pond was historically present within the woodland (as noted in the Hinkley Land Management Reports). This is thought have been located in the central part of the wood near to the western edge where three ditches converge to form a damp hollow. This area no longer holds water throughout the year, although a small amount of water collects temporarily during the wetter, winter months.

The woodland was managed recently by British Energy. Management activities completed include the removal of the dense ivy cover in one part of the ground flora, which has successfully encouraged more species to occur, and selective clearing and replanting of the understorey to maintain the open structure and to continue to allow light to reach the ground. Bird boxes have also been installed on a number of the mature trees.

3.3.9 Woodland I

Woodland I is located to the north of Woodland H, separated from it to the south by the power station access road. This woodland is also located on reasonably flat ground. To the east and north of the wood is the existing power station and to the west is a further access road. The woodland is surrounded by security fencing and is disturbed infrequently.

This woodland is very similar in character to Woodland H, except it appears to have been managed less recently and has a more dense understorey and canopy. The canopy is similar to the other woodlands surveyed, comprising mature ash, English elm, field maple and pedunculate oak. Woodland I also supports small amounts of Monterey Pine (*Pinus radiata*) and sycamore in the southern section.

The understorey is species-rich and supports frequent wild privet, hazel, blackthorn and hawthorn with occasional wayfaring tree, holly and dogwood. The understorey is particularly dense along the east, west and north edges of the woodland.

The field layer is dominated by ivy. The southern part of the woodland (around the pine trees) is much lighter than the rest of the wood and supports a greater diversity of ground flora species include greater periwinkle (*Vinca major*) (probably introduced), perforate St John’s wort, bluebell (*Hyacinthoides non-scripta*), woodruff (*Galium odoratum*) and stinking iris. Nettle and cleavers are common in the ground flora throughout the woodland. In the centre of the woodland hart’s-tongue fern, male-fern and a small area of enchanter’s nightshade are present.

Two banks are present within the wood; one is situated east-west in the southern part of the wood and the other lies north-south through the centre of the wood. Several mature hawthorn trees are located on these banks suggesting they may represent defunct field boundaries. There is also evidence that the hazel within the woodland has previously been coppiced. There is no evidence that the woodland has been significantly managed in the last few years, although it was managed by British Energy through selective felling/clearance and replanting fairly recently.

Table 3.2 Summary of Woodland Condition Features

Woodland	Grid Reference	Size (ha)	Current Structure	Woodland Vegetation Types	Other Habitat Types	Adjacent Land Use	Species Present	Current and Past Management	Historical Presence
A	ST199458	0.3	Established woodland dominated by ash. Sparse understory and underground flora.	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	None	Arable and poor-semi-improved grassland	Common woodland species only.	Evidence of coppicing and hedge laying. No apparent recent management	Broad-leaved trees present from 1904 (conifer in 1887)
B	ST200456	0.9	English elm comprises canopy with limited understorey. Edges more diverse	English elm dominates	Ditch present along northern boundary	Arable and poor semi-improved grassland	Common woodland species only.	Evidence of felling of elms and historical hedge laying around edges	Scrub woodland in 1897, marked as broad-leaved woodland in 1904
C	ST203457	0.9	Established woodland, remnant hedges at the edge and scrub understorey in centre	Closest affinity to NVC community W21 *Crataegus monogyna – Hedera helix* scrub.	None	Arable and poor-semi-improved grassland	Common woodland species only.	Edge remnant hedges previously laid, centre area managed by selective felling, clearance and re-planting to promote diversity.	No woodland shown in 1887 (2 linear fields only), broad-leaved in 1904
D	ST202460	0.9	Open woodland in western part, denser to east with mature oak and field maple	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	Watercourse through centre of woodland	Arable and poor-semi-improved grassland	Common woodland species only.	Evidence of historical coppicing, recent management through selective felling, clearance and re-planting to increase diversity.	Broad-leaved/ scrub woodland present on east side of stream in 1887 and 1904. Woodland not present on west side until more recently

Table 3.2 (continued) Summary of Woodland Condition Features

Woodland	Grid Reference	Size (ha)	Current Structure	Woodland Vegetation Types	Other Habitat Types	Adjacent Land Use	Species Present	Current and Past Management	Historical Presence
E	ST200457	0.1	Although small the structure is well-developed. Ground flora species-poor	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	Ditch through centre of woodland	Arable and poor semi-improved grassland	Common woodland species only.	Evidence of previous hazel coppicing.	No woodland shown in 1887, broad-leaved in 1904
F	ST197456	0.1	Many of the elm are either dying or are young and thin. Limited structure and species-poor ground flora	English elm dominated	Damp ditch around southern edge of wood	Arable and poor-semi-improved grassland	Common woodland species only.	No evidence of management	Shown as broad-leaved woodland throughout, size contracts between 1887 and 1904
G	ST205451	0.4	Few mature trees within canopy, dense understorey layer	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	None	Arable and poor semi-improved grassland	Common woodland species only.	No evidence of past management, currently managed by selective clearance and re-planting to increase diversity.	Conifer and scrub indicated in 1887 in the north part of the wood. Mixed woodland shown in 1904.
H	ST207458	2.8	Predominantly mature standard trees with open understorey.	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	Glades have been created	Buildings and hard-standing, scrub and calcareous grassland mosaics.	Common woodland species only.	No evidence of past management, currently managed by selective clearance and re-planting to increase diversity.	Present as broad-leaved woodland in 1887 and 1904, size increases in the north between these years

Table 3.2 (continued) Summary of Woodland Condition Features

Woodland	Grid Reference	Size (ha)	Current Structure	Woodland Vegetation Types	Other Habitat Types	Adjacent Land Use	Species Present	Current and Past Management	Historical Presence
I	ST207459	1	Few standard trees in canopy, with a dense understorey and patches of more diverse ground flora	Closest affinity to NVC community W8 *Fraxinus excelsior-Acer campestre – Mercurialis perennis*.	None	Buildings and hard-standing, scrub and calcareous grassland mosaics.	Common woodland species only.	No evidence of past management, currently managed by selective clearance and re-planting to increase diversity.	No woodland present in 1887. Broad-leaved woodland in 1904

4. Conclusions

4.1 Habitats

The Phase 1 Survey found that the vast majority of the habitat within the SSA was a mix of intensively farmed arable and pasture land. These habitats support a limited range of common plant species and their loss would be of no more than local importance. Areas of woodland, scrub, calcareous grassland and linear features such as hedgerows and water courses with associated riparian vegetation are of greater potential importance, and are discussed in greater detail below.

The habitat mosaic to the south of the existing power station, comprising scrub and calcareous grassland, creates a species-rich and structurally diverse habitat that is used by a wide variety of fauna. The other areas of calcareous grassland within the site (including the cliff vegetation) are also species-diverse and, whilst they do not support rare plant species, the combination of species present suggests little agricultural improvement (reflecting their origin[5]).

Apart from within the habitat mosaic south of the existing power station (the eastern arm of the SSA), only small areas of scrub occur within the SSA. Throughout the SSA the scrub supports a fairly diverse range of woody species and provides food and shelter for fauna.

The two watercourses within the SSA are small and seasonal, and the vegetation in both shows signs of agricultural improvement. The northern watercourse in particular dries up along the majority of its length and becomes extensively overgrown with tall grass and ruderals, thereby restricting typical aquatic and emergent vegetation. The central watercourse retains more water and is less overgrown allowing a range of aquatic and emergent plant species to occur. Both watercourses also provide infrequently managed and undisturbed habitat corridors through the SSA.

Conclusions relating to the hedgerows and woodlands are provided below.

4.2 Hedgerows

Of the 60 hedgerows surveyed 37 are considered to be ‘important’ under the Hedgerow Regulations.

A total of 17 of the hedgerows are ‘important’ for supporting seven or more woody species within the 30m survey area(s), although 25 of the hedgerows support seven or more woody species within their entire length. The maximum number of woody species recorded growing in a hedgerow was 12 at Hedgerow 42. Hedgerows 4, 11, 30, 31 and 50 supported 10, 11, 11, 10 and 10 species respectively, which demonstrates the high level of species diversity present within the hedgerows in the SSA.

[5] These communities developed on spoil associated with the building of the existing plant.

Although footpaths are located adjacent to a number of hedgerows, only two hedgerows (numbers 2 and 34) are ‘important’ solely because of this (i.e. they would not be ‘important’ due to the limited species present without the footpath). The remainder of the hedgerows next to footpaths are either not ‘important’ or are ‘important’ because they support a higher number of woody species.

4.3 Woodlands

All of the semi-natural broad-leaved woodlands with the SSA are small in size, ranging from 0.1ha to 2.8ha, although all are connected (or virtually connected), to each other by hedgerows. All the woodlands are also situated adjacent to land that is either bare of vegetation or is intensively managed for agricultural purposes. This contributes to the fragile nature of the woodlands by restricting colonisation of typical woodland species and reducing species-diversity. The few hedgerow connections within the site maintain some connectivity between the woodlands.

Although the structure and characteristic dominant species in each woodland vary slightly, all the woods apart from Woodlands C and F, correspond broadly to National Vegetation Classification (NVC) community W8 *Fraxinus excelsior-Acer campestre-Mercurialis perennis.* This is due to the dominance (e.g. Woodland A) or presence of ash and field maple in each of the woods, despite the absence of dog’s mercury (*Mercurialis perennis*). Based on the species-poor ground flora in Woodlands A, D, E, G, H and I, they show most affinity with the *Hedera helix* sub-community of W8. Woodland B supports few ash or field maple trees as it is dominated by English elm. Due to this dominance of elm, Woodland B corresponds more closely to the *Geranium robertianum* sub-community of W8, in which elm frequently occurs in varying abundance.

Woodlands C and F support little ash and field maple, whilst scrub species such as hawthorn and blackthorn are dominant. Therefore, these woodlands correspond better with NVC community W21 *Crataegus monogyna – Hedera helix* scrub. Again, due to the dominance of ivy in the ground flora the woodlands fit best with the *Hedera helix – Urtica dioica* sub-community of W21.

Both these NVC communities occur commonly throughout the UK and can comprise species-rich and structurally diverse woodlands. However, the *Hedera helix* sub-communities of both W8 and W10 present within the SSA are typically species-poor and characteristic of shady, unmanaged woods in south-west Britain, often those of recent origin. The absence of dog’s mercury tends to indicate the recent origin of the woodland.

None of the woodlands within the SSA are considered to be ancient (i.e. documentary evidence indicates they were not present prior to 1600AD) and many have only developed to their current state over the last 100 years. A relatively recent origin of the woodlands is likely to contribute significantly to their species-poor and structurally similar character.

However, it appears from the recent management activities completed in Woodlands C, D, G, H and I that these woodlands have the potential to support a greater diversity of species with suitable management intervention. Additionally, whilst the woodlands are species-poor and do not support rare plant species, they do provide habitat for a range of fauna, including notable bird species such as nightingale and legally protected species such as badger.

APPENDIX 4

ABBREVIATED PLANT NAMES

All plants should be recorded using an abbreviated version of their scientific name. The following list is indicative; additions should be abbreviated using the convention of the first letter name (i.e. the first letter of the generic name and the first three letters of the specific name). Duplicate abbreviations thus created should be clarified by using the BSBI abbreviation or code number. Plants not identified to species should be recorded using initial of generic name and (sp) in brackets. Nomenclature follows Stace (1991).

DICOTYLEDONS

Herbs

Anod	*Apium nodiflorum*	Fool's Water-cress
Asyl	*Angelica sylvestris*	Wild Angelica
Bere	*Berula erecta*	Lesser Water-parsnip
Bcer	*Bidens cernua*	Nodding Bur-marigold
Btri	*B. tripartita*	Trifid Bur-marigold
Cobt	*Callitriche obtusangula*	Blunt-fruited Water-starwort
Csta	*C. stagnalis*	Common Water-starwort
Cpal	*Caltha palustris*	Marsh-marigold
Cpra	*Cardamine pratensis*	Cuckooflower
Cdem	*Ceratophyllum demersum*	Rigid Hornwort
Cmac	*Conium maculatum*	Hemlock
Dful	*Dipsacus fullonum*	Wild Teasel
Dpil	*D. pilosus*	Small Teasel
Ehir	*Epilobium hirsutum*	Great Willowherb
Ecan	*Eupatorium cannabinum*	Hemp-agrimony
Fulm	*Filipendula ulmaria*	Meadowsweet
Lped	*Lotus pedunculatus*	Greater Bird's-foot-trefoil
Lfcu	*Lychnis flos-cuculi*	Ragged-Robin
Leur	*Lycopus europaeus*	Gipsywort
Lvul	*Lysimachia vulgaris*	Yellow Loosestrife
Lsal	*Lythrum salicaria*	Purple-loosestrife
Maqu	*Mentha aquatica*	Water Mint
Msco	*Myosotis scorpioides*	Water Forget-me-not
Mspi	*Myriophyllum spicatum*	Spiked Water-milfoil
Nalb	*Nymphaea alba*	White Water-lily
Nlut	*Nuphar lutea*	Yellow Water-lily
Ocro	*Oenanthe crocata*	Hemlock Water-dropwort
Oflu	*O. fluviatilis*	River Water-dropwort
Phyb	*Petasites hybridus*	Butterbur
Pamp	*Polygonum amphibia*	Amphibious Bistort
Phyd	*P. hydropiper*	Water-pepper
Pdys	*Pulicaria dysenterica*	Common Fleabane
Raqu	*Ranunculus aquatilis*	Common Water-crowfoot
Rcir	*R. circinatus*	Fan-leaved Water-crowfoot
Rfla	*R. flammula*	Lesser Spearwort
Rflu	*R. fluitans*	River Water-crowfoot
Rpel	*R. peltatus*	Pond Water-crowfoot
Rpen	*R. penicillatus*	Stream Water-crowfoot
Rsce	*R. sceleratus*	Celery-leaved Buttercup
Rnaq	*Rorippa nasturtium-aquaticum*	Water-cress
Rhyd	*Rumex hydrolapathum*	Water Dock
Saur	*Scrophularia auriculata*	Water Figwort
Sgal	*Scutellaria galericulata*	Skullcap
Sdul	*Solanum dulcamara*	Bittersweet
Soff	*Symphytum officinale*	Common Comfrey
Tfla	*Thalictrum flavum*	Common Meadow-rue
Udio	*Urtica dioica*	Common Nettle
Voff	*Valeriana officinalis*	Common Valerian
Vaaq	*Veronica anagallis-aquatica*	Blue Water-Speedwell
Vbec	*V. beccabunga*	Brooklime
Vcat	*V. catenata*	Pink Water-Speedwell

MONOCOTYLEDONS

Grasses

Aela	*Arrhenatherum elatius*	False Oat-grass
Asto	*Agrostis stolonifera*	Creeping Bent
Caqu	*Catabrosa aquatica*	Whorl-grass
Dces	*Deschampsia cespitosa*	Tufted Hair-grass
Gdec	*Glyceria declinata*	Small Sweet-grass
Gflu	*G. fluitans*	Floating Sweet-grass
Gmax	*G. maxima*	Reed Sweet-grass
Gnot	*G. notata*	Plicate Sweet-grass
Paru	*Phalaris arundinacea*	Reed Canary-grass
Paus	*Phragmites australis*	Common Reed

Sedges & rushes

Cacu BSBI 340	*Carex acuta*	Slender Tufted-sedge
Cacu BSBI 341	*C. acutiformis*	Lesser Pond-sedge
Cfla	*C. flacca*	Glaucous Sedge
Chir	*C. hirta*	Hairy Sedge
Cnig	*C. nigra*	Common Sedge
Cobt	*C. obtrubae*	False Fox-sedge
Cpan	*C. paniculata*	Greater Tussock-sedge
Cpen	*C. pendula*	Pendulous Sedge
Crip	*C. riparia*	Greater Pond-sedge
Epal	*Eleocharis palustris*	Common Spike-rush

Jacu	*Juncus acutiflorus*	Sharp-flowered Rush
Jart	*J. articulatus*	Jointed Rush
Jeff	*J. effusus*	Soft-rush
Jinf	*J. inflexus*	Hard Rush
Slac	*Schoenoplectus lacustris*	Common Club-rush
Ssyl	*Scirpus sylvaticus*	Wood Club-rush

Other monocotyledons

Apaq	*Alisma plantago-aquatica*	Water-plantain
Alan	*A. lanceolatum*	Narrow-Leaved Water-plantain
Bumb	*Butomus umbellatus*	Flowering-rush
Ecan	*Elodea canadensis*	Canadian Waterweed
Hmra	*Hydrocharis morsus-ranae*	Frogbit
Ipse	*Iris pseudacorus*	Yellow Iris
Lgib	*Lemna gibba*	Fat Duckweed
Lmin	*L. minor*	Common Duckweed
Ltri	*L. trisulca*	Ivy-leaved Duckweed
Pcri	*Potamogetan crispus*	Curled Pondweed
Pluc	*P. lucens*	Shining Pondweed
Pnat	*P. natans*	Broad-leaved Pondweed
Ppec	*P. pectinatus*	Fennel Pondweed
Pper	*P. perfoliatus*	Perfoliate Pondweed
Ssag	*Sagittaria sagittifolia*	Arrowhead
Seme	*Sparganium emersum*	Unbranched Bur-reed
Sere	*S. erectum*	Branched Bur-reed
Spol	*Spirodela polyrhiza*	Greater Duckweed
Tlat	*Typha latifolia*	Bulrush
Warr	*Wolffia arrhiza*	Rootless Duckweed
Zpal	*Zannichellia palustris*	Horned Pondweed

TREES & SHRUBS

Acam	*Acer campestre*	Field Maple
Apse	*A. pseudoplatanus*	Sycamore
Aglu	*Alnus glutinosa*	Alder
Ahip	*Aesculus hippocastanum*	Horse-chestnut
Cave	*Corylus avellana*	Hazel
Cbet	*Carpinus betulus*	Hornbeam
Csan	*Cornus sanguinea*	Dogwood
Cmon	*Crataegus monogyna*	Hawthorn
Eeur	*Euonymous europaeus*	Spindle
Fexc	*Fraxinus excelsior*	Ash
Fsyl	*Fagus sylvatica*	Beech
Iaqu	*Ilex aquifolium*	Holly
Palb	*Populus alba*	White Poplar
Pcan	*P. canescens*	Grey Poplar
Pnig	*P. nigra*	Black-poplar
Ptre	*P. tremula*	Aspen
Pspi	*Prunus spinosa*	Blackthorn
Psyl	*Pinus sylvestris*	Scots Pine
Qrob	*Quercus robur*	Pedunculate Oak
Rfru	*Rubus fruticosus*	Bramble
Salb	*Salix alba*	White Willow
Scap	*S. caprea*	Goat Willow
Scin	*S. cinerea*	Grey Willow
Sfra	*S. fragilis*	Crack-willow
Snig	*Sambucus nigra*	Elder
Ugla	*Ulmus glabra*	Wych Elm
Vopu	*Viburnum opulus*	Guelder-rose

FERNS

Eflu	*Equisetum fluviatile*	Water Horsetail

SELECTED ALIEN PLANTS

Afil	*Azolla filiculoides*	Water Fern
Chel	*Crassula helmsii*	New Zealand Pigmyweed
Fjap	*Fallopia japonica*	Japanese Knotweed
Hman	*Heracleum mantegazzianum*	Giant Hogweed
Icap	*Impatiens capensis*	Orange Balsam
Igla	*I. glandulifera*	Indian Balsam
Mgut	*Mimulus guttatus*	Monkeyflower

Appendix D
Hedgerow Survey Results

Hedge Survey Proforma

Site Name: Hinkley	Date: 19/03/07
Central NGR: ST 214456	Hedge ref number: H1
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 4m

LENGTH: 100m

WIDTH: 1m

PERCENTAGE GAPS: 5%

DESCRIPTION: A short section of hedge that is generally unmanaged adjacent to a public footpath and a watercourse.

WOODY SPECIES PRESENT[1]	Hawthorn	Dog Rose	Blackthorn
Hazel	Elder		
		English elm	**TOTAL: 3 (+1)**

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 2	WOOD:	POND	**TOTAL: 2**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 19/03/07
Central NGR: ST 206456	Hedge ref number: H3
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 5m — LENGTH: 217m

WIDTH: 1m

PERCENTAGE GAPS: 5%

DESCRIPTION: Hedge has evidence of previous management (laying and replanting), with some gaps.

WOODY SPECIES PRESENT[1]	Hawthorn	Dog Rose	Wild privet
Ash	Field Maple	Hazel	
			TOTAL: 6

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE 3	WOOD: 2	POND	**TOTAL: 5**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 19/03/07
Central NGR: ST 203457	Hedge ref number: H9
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 4m

LENGTH: 171m

WIDTH: 1m

PERCENTAGE GAPS: 0%

DESCRIPTION: A short section of remnant hedgerow unconnected to other hedgerows and forming part of green lane

WOODY SPECIES PRESENT[1]	Hazel	Field maple	Dogwood
Hawthorn	Wild privet	Spindle

FEATURES (those present in red)

BANK OR WALL (along at least ½ of the length)	1 STANDARD TREE Per/50M	DITCH (along at least ½ of the length)	PARALLEL HEDGE WITHIN 15M
ADJACENT TO BW/FP (only relevant if there are four woody species and two features)	HEDGE INTACT (gaps totalling less than 10%)	3 FLORA SP (within 1m in any direction of the outermost edges of the width of the hedge)	**Box X** BLACK POPLAR, LARGE SMALL LEAVED LIME, WILD SERVICE TREE

CONNECTIONS

a connection with another hedgerow scores one point and a connection with a pond or a woodland in which the majority of trees are broad-leaved trees scores 2 points. A hedgerow is connected with something not only if it meets it but also if it has a point within 10 metres of it and would meet it if the line of the hedgerow continued. Scores of over 4 equal 1 feature.

HEDGE	WOOD: 2	POND	**TOTAL: 2**

SUMMARY OF WHAT CONSTITUTES AN ECOLOGICALLY IMPORTANT HEDGE (in red if applicable)

7 WOODY SPECIES IN A 30M LENGTH	6 WOODY SPECIES AND 3 FEATURES	6 WOODY SPECIES AND ONE IN BOX X	5 WOODY SPECIES AND 4 FEATURES
4 WOODY SPECIES AND 2 FEATURES IF ADJACENT TO BW/FB	CONFIRMED PRESENCE of legally protected species	PRESENCE of endangered, extinct, rare of vulnerable plants or invertebrates listed in the books referenced in the REGs.	

[1] Red text = those within 30m survey area.

WOODLAND FLORA SPECIES

(Those present in red)

Barren strawberry (Potentilla sterilis)

Bluebell (Hyacinthoides non-scriptus)

Broad buckler fern (Dryopteris dilatata)

Broad-leaved helleborine (Epipactis helleborine)

Bugle (Ajuga reptans)

Common cow-wheat (Melampyrum pratense)

Common dog violet (Viola riviniana)

Common polypody (Polypodium vulgare)

Dog's mercury (Mercurialis perennis)

Early dog violet (Viola reichenbachiana)

Early purple orchid (Orchis mascula)

Enchanter's nightshade (Circaea lutetiana)

Giant fescue (Festuca gigantea)

Goldilocks buttercup (Ranunculus auricomus)

Great bell-flower (Campanula latifolia)

Greater wood-rush (Luzula sylvatica)

Hairy brome (Bromus ramosus)

Hairy woodrush (Luzula pilosa)

Hard fern (Blechnum spic*ant)*

Hard shield fern (Polystichum aculeatum)

Hart's tongue (Asplenium scolopendrium)

Heath bedstraw (Galium saxatile)

Herb paris (Paris quadrifolia)

Herb-Robert (Geranium robertianum)

Lady fern (Athyrium filix-femina)

Lords-and-ladies (Arum maculatum)

Male fern (Dryopteris filix-mas)

Moschatel (Adoxa moschatellina)

Narrow buckler-fern (Dryopteris carthusiana)

Nettle-leaved bell-flower (Campanula trachelium)

Oxlip (Primula elatior)

Pignut (Conopodium majus)

Primrose (Primula vulgaris)

Ramsons (Allium ursinum)

Sanicle (Sanicula europaea)

Scaly male-fern (Dryopteris affinis)

Small cow-wheat (Melampyrum sylvaticum)

Soft shield fern (Polystichum setiferum)

Sweet violet (Viola odorata)

Toothwort (Lathraea squamaria)

Tormentil (Potentilla erecta)

Wild strawberry (Fragaria vesca)

Wood anemone (Anemone nemorosa)

Wood avens (Geum urbanum)

Wood false brome (Brachypodium sylvaticum)

Wood horsetail (Equisetum sylcaticum)

Wood meadow grass (Poa nemoralis)

Wood melick (Melica uniflora)

Wood millet (Millium effusum)

Wood sage (Teucrium scorodonia)

Wood sedge (Carex sylvatica)

Wood sorrel (Oxalis acetosella)

Wood speedwell (Veronica montana)

Wood spurge (Euphorbia amygdaloides)

Woodruff (Galium odoratum)

Yellow archangel (Lamiastrum galeobdolon)

Yellow pimpernel (Lysimachia nemorum*)*

PICTURE(S) OF HEDGEROW:

Hedge Survey Proforma

Site Name: Hinkley	Date: 21/05/09
Central NGR: ST 196458	Hedge ref number: H15
SURVEYOR: Gemma Lee	No. of Photos:

Hedges should be surveyed if they are over 20m in length, are less than 20m but meet another hedge or have gaps less than 20m in length. Hedges around houses or gardens are excluded. Count number of woody species in 30m per 100m of hedge and divide aggregate by 2 (hedges up to 200m) or 3 (hedges over 200m).

APPROXIMATE HEDGE STRUCTURE:

HEIGHT: 2-3m

LENGTH: 186m

WIDTH: 1.5m

PERCENTAGE GAPS: 0%

DESCRIPTION:

WOODY SPECIES PRESENT[1]	Hawthorn	Blackthorn	Hazel
Field maple	Dogwood		
			TOTAL: **5**

FEATURES (those present in red)
